Dr. L. S. Conner thought the combination of change in pitch and change in the sense of resistance imparted to the finger was more important than either one of these alone.

A Case Illustrating the Influence of Arterial Spasms upon the Left Heart.—Dr. Judson Daland, of Philadelphia, read this report, which served as a text for a general discussion on the relation of arterial changes to the heart. The case reported was that of a girl of ten years who had previously been in robust health. The child had a strange fondness for table salt and for a certain kind of table sauce. After having taken about three ounces of this sauce one evening, there were aching bones, headache, fever, anorexia, difficulty in swallowing, and slight convulsions. The urine contained one-fourth by bulk of albumin, and also some red blood cells. The pulse was 95 to 110, and was somewhat irregular. The radial arteries felt like wires under the finger. The physical signs seemed to point to an acute dilatation of the heart rather than to a true hypertrophy. In a few days all of the symptoms and signs had subsided, and when she was discharged, after fifteen days, the urine and blood-vessels were almost normal again. The exact composition of the table sauce could not be ascertained, but it was probable that its chief active ingredient was Cayenne pepper.

Dr. William H. Thomson said that he did not doubt that in scarlet fever and in acute rheumatism there was often an acute dilatation of the heart, which was dependent largely upon arterial spasm. In his opinion, it was one of the most trustworthy means of making the diagnosis of scarlet fever prior to the appearance of the eruption. When a child had been suddenly attacked with vomiting and high fever, with, perhaps, sore throat, there was every reason to suspect scarlet fever if in addition there was a small and high-tension pulse. He had made a series of observations on the specific gravity of the urine in cases of chronic nephritis, and had been astounded at the remarkable fluctuations in the specific gravity from day to day, and even from hour to hour. There was, however, nothing like a periodical fluctuation. In each case the urine for the twenty-four hours had been collected, and the quantity of urea estimated, and in no instance had it been above 13 gm. During the period of observation there had been no change in the diet or medication, and none of the patients had had a hysterical attack. The explanation seemed to be that a sort of vasomotor storm took place in the splanchnic area. These observations also showed that the heart was called upon to deal with intermittent strain, and hence the tendency to cardiac hypertrophy. It had long been known that cases of extensive atheroma of the aorta and of the large arteries might occur without hypertrophy of the heart. It was strain that first produced atheroma. The pulmonary artery did not show atheroma except in cases of mitral stenosis. In all cases of cardio-vascular disease the first question the physician should ask himself was, "Where is the strain?" In his opinion, arteriocapillary disease was always due to a toxæmia, and the one great prophylactic and the one great therapeutic measure in the treatment of chronic vasomotor diseases was fresh air, because this did the most to counteract the chemical changes going on in the blood.

Dr. Beverley Robinson said that physicians often relied to some extent upon appreciable arterial changes to help them in making the diagnosis of the more obscure cases of cardiac hypertrophy. He had noted in many chronic conditions marked fluctuations in the constituents of the urine at different times in the twenty-four hours. Referring to treatment, the speaker said that, as it was generally accepted that under certain conditions cardiac hypertrophy was the most conservative effort of nature, one should not rashly prescribe nitroglycerin and endeavor to overcome the hypertension of the arteries. He closed with a scathing criticism of what he called one of the medical fads of the day, *i.e.*, persons going abroad to certain spas in order to have their arterial changes favorably modified, and returning home with numerous charts to show that they had a little more or a little less heart than when they went away. He expressed most emphatically his belief in the comparatively limited and well-defined limits in which the Schott-Nauheim treatment was useful.

Dr. Morris Manges thought Dr. Daland had overlooked the effect of the myocardial changes which inevitably took place in the acute infections. When the coronary vessels were not involved, it had been shown that the strain could be well borne for a long time. General arteriosclerosis might exist without any hypertrophy of the heart at all. The case reported by Dr. Daland, while interesting, should not be used too freely in the effort to explain arteriosclerosis and arterial spasm.

Dr. Andrew H. Smith said that it was now pretty well settled that the aortic tree and its branches might be considered a continuation of the heart, and that there was active muscular work going on throughout the whole arterial system down to the smallest branches containing muscle. There must be a nervous influence behind all such muscular effort, and hence arterial spasm should be a subject of great importance. If the effort of the heart were actively seconded by a sort of peristaltic action throughout the arterial system, the work of the heart must be lightened. On the other hand, if the muscular effort were against that of the heart, the strain on that organ must be very greatly augmented. Toxic materials in the blood acted upon the muscular coat by direct irritation.

Dr. Richard Van Santvoord said that in his own practice he frequently met with a pulse which felt small and weak to his finger, and yet the sphygmograph showed the pulse to be one of high tension. He had also come to believe that the loudness of the second sound of the heart was not an indication of high arterial tension or of strength of the heart. Loud heart sounds were often observed in persons evidently in a state of great debility. This was probably to be explained by the fact that the snap of the valve depended upon the difference in the blood pressure on two sides of the valve.

The Climate of Long Island.—Dr. Le Grand Denslow read a paper on this subject. He said that Long Island as a whole was comparatively flat, though there was a chain of hills having an average height of one hundred and fifty feet. The greater part of the island consisted of sand and clay. The eastern end and the south shore were the coolest portions in summer. The winter temperature was slightly higher at the eastern than at the western end. Long Island was influenced by the prevailing westerly winds. The average summer temperature of the eastern end, as represented by Block Island, was lower than that of any other point on the Atlantic coast between New York and Florida, except Nantucket. One of the most marked climatic features of the eastern end of Long Island was the amount of sunshine, there being at Cutchogue over one hundred more days of sunshine than at New York City. The speaker said that he was unable to account for this limited area of dryness and sunshine situated so near New York City that it could be reached by a journey of from one to three hours, but this region should prove very suitable for the relief of many cases of heart, lung, and kidney diseases, and for rheumatic affections.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 4, 1901:

	Cases.	Deaths.
Tuberculosis	283	147
Typhoid fever	22	11
Scarlet fever	642	38
Measles	319	9
Diphtheria and croup	288	45
Smallpox	86	10
Cerebro-spinal meningitis	0	5

Hard on the Physicians.—A Hoosick Falls correspondent writes to the *Troy Times* that quotations from tombstones seem to figure prominently of late in the *Troy Times* and other leading newspapers of to-day, and suggests that that village, being always up to date, has a contribution to offer that may be worthy of a place among the most odd and quaint, and which can be seen and read at any time in the daylight. In Maple Grove cemetery, south of the post office, there is a headstone, upon which is the following:

> "Her body was stolen by fiendish men,
> Her bones anatomized,
> Her soul we trust has risen to God,
> Where few physicians rise."

Salubrious Cuba.—The New York *Evening Sun*, commenting editorially upon Major Gorgas' glowing report of the sanitary reforms introduced into Havana by American methods, says: "Colonel Waring, of New York, introduced the system of sanitary treatment which has converted Havana into a health resort, so to speak. It has been extended to other Cuban cities, and it appears that the results have been fully as satisfactory as in the case of Havana. For instance, the death rate of Santiago in February was 2.05 per 1,000, and that of Guantanamo only 5.77. Both places were notoriously unhealthy before the war. February, however, has generally shown a lower death rate in Cuba than any other month. Major Gorgas can rejoin that, even so, the death rate in Havana for February of this year was lower than for any preceding February during twelve years. The virulent fever months in Havana have usually been July, August, September, and October. If these months in 1901 pass with a fairly clean bill of health, we shall know that yellow-jack is no longer a menace to Havana, for the returns in 1899 and 1900 were most encouraging. The sanitary reforms which the United States have given Cuba should be a durable title to her gratitude."

Health Reports.—The following cases of smallpox, yellow fever, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended May 3, 1901:

		Cases.	Deaths.
Smallpox—United States and Insular.			
California, San Francisco	April 13th to 20th	2	
Illinois, Chicago	April 20th to 27th	9	1
Freeport	April 20th to 27th	1	
Indiana, Evansville	April 20th to 27th	1	
Kansas, Wichita	April 13th to 20th	30	
Kentucky, Lexington	April 20th to 27th	2	
Massachusetts, Fitchburg	April 13th to 20th	2	
Holyoke	April 20th to 27th	1	
Michigan,* Bay City	April 13th to 20th	5	
Detroit	April 20th to 27th	1	
Minnesota, Minneapolis	April 16th to 22d	8	
Nebraska, Omaha	April 13th to 20th	11	
N. Hampshire, Manchester	April 20th to 27th	5	
New York, New York	April 13th to 27th	94	18
Ohio, Cincinnati	April 19th to 26th	4	
Pennsylvania, Allegheny City	April 12th to 19th	3	
Johnstown	April 13th to 20th	1	
Philadelphia	April 13th to 27th	12	2
Steeltoa	April 20th to 27th	1	
Williamsport	April 20th to 27th	3	
Tennessee, Ducktown	April 20th	Present.	
Memphis	April 13th to 20th	24	
Nashville	April 20th to 27th	14

THE RECENT BUFFALO INVESTIGATIONS REGARDING THE NATURE OF CANCER.[1]

By ROSWELL PARK, A.M., M.D.,

PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO.

At the risk of tedium on your part, I have ventured to select as the subject of my address to you a topic upon which I have been repeatedly heard during the past few years. This subject of cancer has been for the pathologist the mystery of the ages, and continues to be the subject of active and profound study in all quarters of the world, with now a promising hope of eventual solution. It would appear to be about the only local disease concerning which there is still much of the uncertain and the unknown. Diseases like scarlatina and syphilis, for instance, for which we readily acknowledge a contagium vivum, are widespread, and in no sense localized among the tissues; but the more one studies cancer the more he becomes convinced that in its inception it is purely local, and that the process of generalization is relatively slow save in certain rare instances. The older views about the constitutional nature of the disease, then, may be set aside as absolutely untenable, and we have nothing left to do now except to consider it in its thus limited relations.

Pathologists, who study it purely from the deadhouse point of view, have confronted some of the greatest problems which it has to offer, but have also missed some of its most important aspects. On the other hand, the operating surgeon, who sees in this mystery only the question of how far he may go with the scalpel, misses also the fundamental theories of its origin and the consideration of its etiology upon which its whole successful therapy must be based. Only by a combination of ante- and post-mortem studies can its nature be solved. All this became so exceedingly evident to me many years ago that I began a series of studies upon the disease, both with regard to its nature and its operative treatment, which have been my excuse for the numerous communications which I have made upon the subject.

Microscopical sections alone may well arouse the numerous hypotheses which are now in vogue as to the peculiar behavior of cells and their reactions. But the clinician who is to study the disease in its various phases may well criticise every theory which ascribes cancer to purely intrinsic causes, even though he be forced to acknowledge that he cannot absolutely demonstrate an extrinsic cause. Nevertheless, so much has been done in the past five years that I, for one, have not hesitated to avow myself a firm believer in the later teaching as to the infectious nature of the disease, a theory, indeed, which I have held to and taught for nearly fifteen years.

The parasites of cancer, be their nature what it may, are in all probability polymorphic in extreme degree and masquerade under many forms, changing with their different stages of reproduction. So much of the personal equation enters into their consideration and investigation that one must know an individual and his methods before one knows exactly what estimate to place upon his work and the weight to be attached to his views. Take the work, for instance, of Borrel.[1] In 1892 he published a monograph on the cellular evolution and parasitism of epithelioma, in which he claimed that for four years he had continuously and carefully studied the subject, and convinced himself that there was no doubt about the parasitic feature of these cases; he claimed priority in establishment of parasitism for Malassez.[2] Borrel, like most French investigators, is attached firmly to the parasitic hypothesis, but is of the belief that the parasites in question are protozoa, *i.e.*, are of animal origin. In the plates which he published nine years ago, there may be seen the same peculiar appearances which most other observers since his time have noted. In this connection one may say that the most striking feature of all these studies, as one compares the plates of various writers, is the fact that they all agree as to the extraneous nature of certain cells which they picture in various stages of cell division or reproduction, though they nearly all differ in the peculiar interpretation of those phenomena which they illustrate, differing as well in names as in classification of the parasites, differing even in the kingdom to which they assign them, *i.e.*, animal or vegetable. It is most suggestive in one regard, though somewhat disturbing in another, to see practically the same parasitic forms described and figured by an Italian writer as showing the presence of blastomycetæ, while the French would call them protozoa, and most of the German scholars would indicate them as mere products of cell degeneration. This only illustrates, however, that, to a considerable extent at least, the variations which appear so great between different observers merely concern differences of interpretation. I do not see how one can study the illustrations of this subject, still less the actual sections, without being firmly of opinion that parasitic forms are certainly present, although he may be absolutely in the dark as to their minute nature; just as no man can come long into contact with the clinical features of the disease without feeling that cancer must be considered as an expression of infection of some kind, but not necessarily committing himself as to the minute nature of the infectious element.

Let me here repeat the essential feature of an argument which I brought before this association in 1898, with regard to the infectious nature of cancer. I have found that the length of time over which this infection, if such it be, may extend, as well as the period of incubation, are in many cases the principal arguments which the opponents of this view advance against its accuracy. Such argument as this, however, must fail from what we already know of other infections. For instance, there are infections which kill within a few hours from the appearance of their first lesions, such, for instance, as bubonic plague, cholera, etc.

[1] Being the president's address before the American Surgical Association, at its Baltimore meeting, May 7, 1901.

[1] "Evolution cellulaire et parasitisme dans l'épithélioma," 1892.

[2] Archives de Méd. Exp., 1890, 2.

These constitute the most acute and disturbing type of their kind. The time limit of others is measured by days, as, for instance, in the case of tetanus, variola, pneumonia, and meningitis. In yet others the course of the disease is run within only a few weeks, as in the case of typhoid fever. Tuberculosis and actinomycosis, again, run their course in a few months, while in the case of syphilis and leprosy ordinarily the time in which they kill by their own ravages is measured only in years. No violence then is done to the general acceptance of the theory of infection if we suppose that cancer is a disease whose duration of infection may extend anywhere from weeks to years.

There is no other disease which is characterized by metastasis in which the pathologists decline to see evidences of parasitism. When one considers the more acute expressions of metastatic infection which he may see in surgical and puerperal sepsis, for example, or the slower forms seen especially in tuberculosis, they all convey the same meaning to the careful studient, *i.e.*, they imply that some infectious element has been transported from one part of the body to another, there to set up disturbance similar to that existing at the point of departure. Why should this explanation be acceptable in the cases of all other diseases and so difficult of acceptance in the case of cancer? For myself, as I have often remarked, every metastasis of cancer has the form and significance of an inoculation experiment, only performed under the most favorable because natural conditions.

The primary question after all is the general one of parasitism. Are not parasites at fault? It has not yet been reduced to a question of just which parasite. However, if analogy assists one at all, he must not forget that there are numerous organisms which may produce pus formation, and these not alone belonging to one animal kingdom. Why, then, may it not be so with cancer, that not one organism alone, but perhaps numerous forms are at fault? In my opinion, it may and probably will be found that cancer is not a question of any single organism, possibly not even of a single class.

Roger Williams, though acknowledging its inoculability, has very little faith in the transmission of cancer from one human being to another, even by contact, and he quotes Demarquay, who collected one hundred and thirty-four cases of cancer of the penis, whereas in only one instance was the wife affected with uterine cancer.

With regard to its inoculability he acknowledges that the evidence is so weighty as to be practically conclusive. Aside from instances to which I have already alluded in other papers, I quote, *e.g.*, the following: Cripps has reported the case of a woman with extensive cancerous ulceration of the left mammary region, who, being unable to wear any dress, has kept her arm bent at a right angle and in constant contact with the disease for several months; in consequence of which the skin in the vicinity of the elbow became the seat of a cancerous ulcer several inches in diameter. A similar instance has been already reported by De Morgan. Instances of the spread of disease by contact infection from the uterus to the vagina have been reported by Thorn and many others. Thorn's case was in a woman, aged forty-six years, whose uterus had been deflected to the right and retained by adhesions. Owing to this bad position the cancerous excrescence was constantly in contact with the left side of the vagina, where another cancer developed which fitted that on the cervix "like a saucepan lid." Elsewhere the vagina was free from disease. Numerous cases are on record in which the primary outbreak of the disease in the fundus has been followed by similar lesions of the cervix. The cases in which cancer of the upper alimentary tract has been followed by others lower down are common, and Moxon has described the spread of the disease along the trachea to the lungs in a similar way. Cancer in the pelvis is often apparently due to infection with nodules detached from cancerous growths in the upper part of the abdomen, while visceral cancer projecting into the peritoneal cavity often infects the exposed tissue with which it comes in contact. Numerous cases are now on record of cancer along the track of the trocar used in tapping for ascites due to cancerous disease. Surgeons now quite generally admit this traumatic dissemination of the disease by inoculation of wounds during operations. Schopf reports cancerous infection of the lateral incisions into the vagina and vulva necessitated in the course of vaginal hysterectomy for cancer.

Roger Williams closes his section on this subject by repeating the warning now so often given, that care should be taken to avoid cutting into the malignant neoplasms during their removal, for "such is the great tenacity of life and the wonderful proliferative power of even the most diminutive fragments of cancer, that when left behind they only too often constitute fresh centres of disease." If this is not a virtual admission of the infectious nature of the disease by one of its strongest opponents, I scarcely know how to regard it.

It will probably not be amiss if now I ask your attention to some recent work which has been done in the State laboratory, conducted under the auspices of the University of Buffalo. We have enjoyed exceptional facilities in that laboratory for the study of cancer, it having been founded for the purpose, and generously maintained and supported by the State. Some years ago I outlined in a paper, which partly treated of this subject, the general lines of investigation which I thought it would be necessary to follow in order to arrive at more accurate notions regarding the nature of cancer. Those included not only the ordinary histological and bacteriological methods of investigation, but I also at that time insisted that the subject should be studied from a biological and from a chemical standpoint. The latter method had never been undertaken in any systematic way until we began it in this laboratory, where we have now a competent biological chemist, and are at last able to study the disease in some of those relations which have been hitherto either misunderstood or not understood at all. The studies already made have seemed to render it clear that death in cases of cancer comes about, as in so many other diseases, by a sort of terminal infection, which is a conspicuous feature of the disease, and has not hitherto attracted sufficient attention. It appears to us as though the end is finally brought about by a distinct toxæmia, and particularly by a sort of hæmatogenous infection. This has been made clear by a study of the experimental rather than of the clinical side of the disease. In all our animals inoculated and injected, this feature has become so very distinct as to be positively striking. The exact nature of these terminal changes has not yet been made out beyond what is implied in the term "hæmatogenous." Moreover, as I have previously indicated in another paper, the cachexia which is so pronounced a clinical feature of cases of cancer is produced by varied and varying causes, and it is hard to ascribe to the distinct toxæmia of this disease its proper rôle. Much more can be learned about the disease by experimental research than by speculation concerning clinical features.

In a paper which I presented to this association in 1898, I argued at some length for the infectious or parasitic nature of this disease. At that time I had just returned from Italy, and was particularly conversant with the work done by the Italian investigators, who seemed to be almost unanimous in belief as to the vegetable, *i.e.*, fungous nature of these parasites.

If in the succeeding years views regarding their nature have gradually changed, it may be but a natural outcome of further acquaintance with the bodies in question and a more complete recognition of their extraordinary polymorphism, as well as our ignorance regarding the protozoa, especially of their life histories. The predictions of the Italians have failed in many respects, and it is by no means so easy successfully to inoculate animals with the yeast as had been generally supposed, but the differences that have come about in our own views in Buffalo have been essentially the outcome of our own experimental work. Perhaps I can best illustrate this by epitomizing some of the work as recently reported by my colleague, Dr. Gaylord, who really has directed it and is entitled to the credit of it.

In August, 1898, I explored the abdomen of a patient, the case being one in which a clear diagnosis of intra-abdominal carcinoma could be made; but beyond that no accurate conclusions were reached, because of the distention by ascitic accumulation. The fluid from the patient's abdomen was collected in abundance, and it was in this fluid that the bodies which have since so attracted attention were by us first observed. Anatomically the case eventually proved to be one of adeno-carcinoma, probably arising from the appendix, spreading, involving the greater portion of the peritoneal surface of the omentum and mesentery, and then undergoing mucoid degeneration to such an extent that when the abdomen was opened at the operation simply a mass of soft cancerous contents was exposed. The fluid, which was removed through a sterile tube, and remained bacteriologically sterile at the end of two weeks, contained a large number of small hyaline bodies which, under the microscope, were seen to change in size and form and to pass through a cycle of development up to what appeared to be a spore-forming stage. These bodies were at first mistaken for fat droplets, but did not react to ether or osmic acid, as fat usually does. They were injected into animals. Those which received injection into the peritoneal cavity developed no tumor formation, but marked peritonitis and enlargement of local lymph nodes. In their peritoneal fluid the same characteristic spherical nucleated bodies, or sacs filled with granules, were found. When these bodies were kept a few days in a thermostat they not only changed their form but apparently developed into larger structures, in many of which pseudopodia were seen. In one slide at least twenty such organisms were arranged around an air bubble, all of them with long pseudopodial projections, as though by some chemotactic excitation. Another animal whose jugular had been injected was found, fifty days after injection, with white nodules in the lungs, which on microscopical examination proved to be minute adeno-carcinomata. The tumor cells, as well as cells from enlarged follicles found in the spleen, were seen to contain adventitious bodies of unusual appearance. Those of the splenic pulp corresponded to Russell's fuchsin bodies, while in the perivascular spaces Plimmer's bodies, *i.e.*, half-grown organisms, were found in large numbers, just as he has found them in carcinoma on man.

Attempts to cultivate these organisms at the time were not successful; but success was met with later, the culture medium giving the best results being that recommended by Celli for the cultivation of amœbæ, *i.e.*, a bouillon made with fucus crispus. Other animals inoculated at this time also developed evidences of peritonitis, splenic enlargement, and pulmonary œdema. In their peritoneal fluid, as well as blood, and in the organs, large numbers of these parasites were detected, while sections since stained by Plimmer's method revealed the presence of numerous parasites in all of the viscera, especially in the lymphatics.

As an outcome of the experiments we were specially directed toward investigation of fresh scrapings from cancer. Starting with the assumption that the small spherical bodies which so closely resembled fat are not fat, Dr. Gaylord endeavored to determine how the great discrepancy between the large number of parasites found in fresh cancer and the small number in sections could be accounted for. Moreover, examination of numerous tumors shows that in all rapidly growing tumors a great number of organisms are present. Comparing tumors removed by operation with those removed post mortem, it became evident that the organisms either increase rapidly during the period just before death or that they proliferate in the tissue immediately after death. In two cases of large tumors examined immediately after operation, and found to contain numerous organisms, which yet remained sterile to ordinary methods, the following observations were made: Repeated examinations of successive scrapings made at intervals of several hours showed that the relative size of the organisms increased. In the course of ten hours repeated scrapings showed that amœboid forms were greatly increased in number, and that after twenty-four hours the "morula" or spore-bearing stage had been reached. At the end of three days the spore sacs were completely replaced by groups of hyaline bodies considerably larger than those which the sacs originally contained. From this it would appear that the so-called fatty degeneration of carcinoma cells is at least in some part due to the presence of organisms which have been mistaken for fat droplets or for epithelial cells in advanced fatty degeneration.

It was also possible to determine that cancer juices (or so-called cancer milk of some of the older writers) consist almost entirely of pure culture of these organisms; also that fluid from malignant ovarian cysts contains them in large numbers, as does also the peculiarly characteristic soft mass found in the cavities of certain adeno-carcinomata of the ovaries. Thus in practically all scrapings from cancer could be seen either small hyaline refractive forms, which in suspension possess a characteristic oscillating motion, or larger forms with projecting pseudopodia, or saccular forms containing very refractive spherical bodies. By incubating hanging-drop preparations of fresh scrapings from cancer, the smaller forms can be followed in their development as they increase in size; and if kept upon a warm stage they may be seen to throw out especially developed nuclei and conclude their life history by a formation of a sac in which they develop their spores. Since the specific gravity of these organisms is less than that of water, they rise to the surface in the hanging drop, and are to be sought directly beneath the cover slip, and not in the lower portion of the fluid.

Having learned the nature of these changes in the hanging drop outside the body, it became necessary next to determine why they could not be more easily demonstrated in the tissues by ordinary staining-methods. It was then found that nearly all the fixatives in common use cause the disappearance of all the spore sacs and the greater part of the more developed organisms. Only two small, more resistant forms remained, and these would take the ordinary aniline stains. These now appear to be those forms seen so long ago by Russell and so generally known by his name. A little later in their life history these reach such a stage of development and size that it is often impossible to state whether they are parasites or tissue elements. In one case, however, of carcinoma of the bladder in which these organisms appeared in large numbers in the urine, Gaylord was able to detect these forms between epithelial cells and attached to the surface of the tumor after its removal.

Another experience encountered in the summer of

1898 made a profound impression upon our minds. An autopsy was made upon a patient who had died of carcinoma of the uterus. It disclosed advanced general peritonitis, with abundance of fluid, such as would ordinarily be produced by perforation and extension. It was found, however, that there was absolutely no perforation, and the peritonitis seemed to be due to a general infection whose source was to be traced. Further preparation was made by Gaylord from the surface of the peritoneum, the spleen, the lungs, and the blood, showing large masses of pale hyaline forms seen so often in fresh scrapings, in the peritoneal fluid of cancer, and in the blood and fluids of experimental animals.

In January, 1899, before the Medical Society of the State of New York, Dr. Gaylord and myself both stated that we believed he had recognized and demonstrated the presence of parasites in cancer and had successfully reproduced cancer in animals, but that we were at that time not in a position to state positively the nature of these parasites. Since that time most elaborate studies have been made, both of experimental animals and by post-mortem examinations of patients dying of cancer, and Dr. Gaylord is now able to demonstrate that all the organs of patients dying of cancer, including sarcoma and epithelioma, as well as the blood, contain large numbers of the organisms.

What now shall be said with regard to the yeasts and the fungi which numerous observers, especially among the Italians, believe to be the actual parasites of cancer? It certainly is true that Sanfelice has produced neoplasms, essentially tumors, in animals, by inoculation with the yeasts which he cultivated; but this occurred only in isolated instances, and can be regarded as proving only that the yeasts are pathogenic but not certain cancer producers. That fact had already been made plain by Busse, independently of the Italian observers. The yeasts certainly have their pathogenic rôle and are now known to produce certain skin lesions, as well as to be associated with certain internal diseases, and occasionally with the formation of pus. Nothing has yet been established to prove that they may not in occasional instances produce cancer; but so far at least as the Buffalo researches are concerned, we have to report that the Italian observations have been neither absolutely disproven nor confirmed. Sanfelice was unable to cultivate the organisms from the region of inoculation, but was, in many instances, able to regain them from the regional lymph nodes. By transferring these from animal to animal he enhanced their virulence to such an extent that they became fatal to the animals in which they were injected.

Further difficulty is added to this line of investigation by the extraordinary polymorphism of many of these minute organisms. Even the yeasts and fungi undergo numerous changes in size, and doubtless this is probably true to greater extent of the protozoa.

Plimmer, of London, has rendered most signal service in this direction by his extraordinary patience and the number of his investigations. During a period of six years he examined microscopically twelve hundred and seventy-eight carcinomata. In eleven hundred and thirty of these cases he found those parasitic bodies which are now associated with his name. They were found in all portions of the cancer, but especially at the growing edges. They appear only in the active cells, and not in those which are undergoing degeneration. They appear also between the cells and even in the leucocytes. In the more rapidly growing tumors they are found in large numbers. He has found even as many as sixty in one cell. Comparing sections of cancer with those of other growths, granulomata, etc., as well as normal tissues, he stated positively that he had never seen in any instance save in cancer bodies which resemble these parasitic forms or which have their reactions. The claims made by Plimmer have been almost faithfully corroborated by work done in the Buffalo laboratory, and substantiate his claim that these bodies are present in practically all carcinomata. They may be demonstrated in the fresh state, although here it is somewhat difficult to differentiate them from the fat droplets which they resemble. The most minute forms might be confused with cocci. The maturer forms appear either as spherical bodies with delicate outlines, or in full form, as well within as without the cells. Sometimes pseudopodia may be seen, in which case their contained granules remain, for the most part, in the larger portions of the structure. Sometimes the extra-cellular bodies may be noticed to change their form by placing them in a thermostat. Summing up these investigations of Plimmer's bodies, it may be stated that they present characteristic appearances, and can be differentiated from cell degenerations of the usual type as well as from other structures which they may resemble. It has never been possible to make out degenerative changes in the epithelial or other cells in cases of cancer which can really be confused with the so-called Plimmer's bodies.

It is extremely probable that most, if not all, of the observers who have described and figured cell inclusions have been watching the typical Plimmer's bodies. This is particularly true of Sjöbring.

Culture experiments made in our laboratory by the ordinary bacteriological methods have been uniformly negative in result. In order to show that they have been assiduously tried, I would say that sixty-four different media, including about everything that has ever been suggested and some original formulæ, have been employed, and of various degrees of acidity and alkalinity. Per contra, the organisms have been usually obtained by cultivation after experimental inoculation in animals. In those instances in which the yeast was employed, it has been possible to produce a pretty typical blastomycetic mycosis with abscess formation, or characteristic infectious granuloma.

Matters rested in this state in our laboratory for two years, our staff—and especially Dr. Gaylord—varying in opinion, as the evidence seemed to present itself one way or the other, inclining at times to the view that the parasites were fungi, and at other times that they were protozoa, the difficulties of the research being such that it seemed most difficult to weigh the evidence and reach a satisfactory conclusion. This was, however, at last and recently hastened by the investigations of Copeman and Funk on the protozoa of vaccine lymph. Sections of rabbit cornea, which had been inoculated with vaccine virus, showed not only that the half-grown formation of the vaccine organism is closely related in appearance to Plimmer's and Russell's bodies, but that the life cycle of this organism seemed to epitomize that of the cancer parasites which we had been studying. Going over the old work which had been done by methods previously in use, in the light of these latest researches on vaccine organisms, very positive conclusions can now be reached.

It would appear, for instance, that the protozoa are capable of producing in man (as Pfeiffer showed that they might produce both in man and in animals) lesions of widely different nature from mere infection of epithelium. For instance, in a pustule found upon the surface of a cancerous breast which I removed in February of this year, Dr. Gaylord found a quantity of material, consisting of leucocytes, red corpuscles, and a very large number of cells which proved to be protozoa. On cutting into the breast and making fresh scrapings these were found to consist of closely packed epithelial cells, fat droplets, and a considerable number of small greenish hyaline bodies of high refractive

index, and corresponding in every way to the Plimmer's bodies and to the parasites already described. Sections stained in the ordinary way, as well as by Plimmer's method, show also the same condition. Sections of the region of the pustule above mentioned show a tremendous number of spherical and oval Russell bodies, as well as large cells with more than one nucleus, many of them containing spherical bodies like Russell's. This pustule would appear to have been the result of an embolic deposit of parasites from the cancer itself, and we naturally interpreted it as indicating that the organisms of cancer are capable of producing other lesions than mere epithelial infection.

In a short time full report will be made of the results of inoculation of seventy-two animals. The material with which they were inoculated consisted of peritoneal fluid, fluid from the interior of malignant ovarian cysts, bacteriologically sterile cancer, and dried cancerous lymph nodes, rubbed up with salt solution. Some of the latter contained metastatic cancerous deposits, while in a number Russell's bodies were detected. In each case the fresh material was carefully examined and the presence of parasites determined before inoculation.

Briefly epitomizing the results obtained, we have the following interesting features: Fourteen guinea-pigs inoculated in the peritoneum with peritoneal fluid containing the organism had an average life of fifty-eight days; four, inoculated in the peritoneum with cancer mush, an average length of fifty-eight days; eleven, inoculated in the peritoneum with dry cancerous lymph nodes, forty-five days; while six guinea-pigs inoculated with material from these animals already infected gave an average length of life of twenty-nine days, but little more than half the length of time for the animals inoculated directly from man. Only one interpretation can be put upon this, and that is the increased virulence obtained by passing the organisms through even one animal. By other experiments organisms grown in a collodion sac within the peritoneal cavity of rabbits were so enhanced in virulence that a healthy rabbit inoculated in the ear vein died within fifteen days of general hæmatogenous infection. Thus, it will be seen that animals are rapidly infected when inoculated with cancerous material proven to be bacteriologically sterile, and consisting essentially of pure culture of the cancer parasites. All these animals rapidly emaciated and presented, on opening of the abdominal cavity, enlarged peritoneal lymph nodes, an increase in fluid, and enlargement of the spleen. Several of the animals presented also minute nodules in the lungs, which we are quite justified in interpreting as beginning adeno-carcinoma, while similar nodules were noticed in other instances in the liver and the spleen. In all of the organs thus far examined by Plimmer's method, large numbers of parasites were found in various stages of development. The lungs, in all instances, show that the parasites have penetrated the bronchial epithelium, causing a typical proliferation and epithelial nests beneath the basement membrane, practically such lesions as Pfeiffer described ten years or more ago in many of the lower forms of animal life.

The mention of protozoa as active agents in the production of cancer will strike no one as a novelty. The lowest forms of animal unicellular life have been regarded, as it were, as disease-producing agents for a number of years. Among the most conspicuous investigators of this subject has been L. Pfeiffer, of Weimar, who has published monographs at various times on this special subject. Published as they were, they seem to have attracted less attention than they deserve, or would if they had been printed in some journal of wide circulation. So early as 1890, Pfeiffer had written and studied most extensively on this subject, and his investigations are remarkable examples of the fidelity and patience with which some of the Continental investigators pursue studies.

Then we have had recent description of Eisen's cancriamœba, showing that so far as the microscope alone could take him he was working in the right direction. There is also, for instance, Korotneff's Rhopalocephalus carcinomatosus, which he has figured and described with infinite pains.[1] There are, further, Bosc's descriptions and plates of myxosporidia, coccidia, etc., which present very similar appearances. But the most elaborate monographs of all dealing with this side of the subject are those of Pfeiffer.[2] He attacks the matter from the comparative standpoint, which is by far the most successful one, and shows, for instance, how epithelial proliferation is provoked in the lower forms of life, and by many parasitic forms belonging to the protozoa. Thus Clepsidriana will produce in the intestine of the golden beetle (Chrysomela) and the horned beetle (Carabus) epithelial proliferation by which a heaping up of cells and almost miniature tumor formation are produced. This is particularly true in the case of the intestinal lesions produced in the beetle by Actinocephalus. Tumor formation in the spertoblastic cells of the earth-worm is produced by certain of the monocystidia, while Klossia produces a similar effect in the kidney tissue of certain snails. Coccidiosis is now well known, especially in the rabbit and the domestic mouse, as the explanation of certain neoplastic lesions. Infection by certain sporidia produces general muscle tumors in the hog, sheep, horse, and other animals. The name myositis gregarinosa is given to certain muscle tumors caused in the horse by sarcosporidia, and to tumors in the œsophagus and pleura of sheep produced by similar organisms. Pfeiffer found also muscle tumors produced in pickerel and other fish by myxosporidia, as well as tumors of various viscera, and even the heart substance. These parasites also produce neoplasms in nerve trunks, thus leading to lesions which he describes as polyneuritis parasitica. They also produce tumors in the swimming bladders of the horse-mackerel (Caranx), which he considers expressions of endothelial infectious tumors.

A close study of these comparative lesions and of tumor formations in human beings leads Pfeiffer to say: "When the cancer parasite is an obligate cell, parasite cultivation, according to ordinary bacteriological methods, cannot succeed; or, if at all, probably only in the hen's egg as a medium" (p. 97).

Having thus called your attention to some of his researches upon the rôle which the protozoa play in comparative pathology, let me remind you of what he has done and found concerning their activity as disease-producing agents among human beings. The dermatologists meet frequently with a disease which we call molluscum contagiosum, which is known among the Germans often as epithelioma contagiosum. A similar lesion is met with also in birds, and especially among domestic fowl, pigeons, etc., and is seen upon the head, neck, eyelids, inner surface of the thighs, and about the anus. In birds it seems to be often accompanied with a formation of false membrane upon mucous surfaces, giving rise to the term avian diphtheria. This, however, is a most unfortunate expression since it has nothing whatever to do with our diphtheria. In human beings similar tumors appear on all parts of the body, and seem to possess a certain degree of contagiousness or infectiousness. Thirty years ago Virchow called attention to the resemblance between the so-called molluscum bodies and certain protozoa found in the intestine and liver of rabbits. In 1873

[1] "Sporozoen als Krankheitserreger."

[2] "Die Zell-Erkrankung und die Geschwulstbildung durch Sporozoen" and "Die Protozoen als Krankheitserreger."

Bollinger called attention also to the resemblances between these new formations and what was known as bird-pox. He it was who first gave it the name of epithelioma contagiosum. In 1890 Pfeiffer fully described the peculiar infection of the epithelial cells by protozoa, and figured characteristic appearances in his book. He also showed, as have Darrier and Wickham, the protozoan nature of Paget's disease of the nipple, agreeing with these other authors as to the nature of the disease, and illustrating the gradual invasion of the milk ducts by these parasites.

Pfeiffer also called attention to the changes occurring in epithelial cells in herpes zoster and the eruptive diseases of children. He showed how in a fresh herpetic vesicle the epithelial cells could be found packed with protozoa, and how the latter could be also seen in the fluid and in the tissues. Similar vesicles produced by burning, by croton oil, etc., did not show these evidences of parasitic infection. This is of practical interest in connection with some of the herpetic eruptions seen along with cases of cancer. In a later monograph published in 1895, Pfeiffer claimed to be among the first who had determined the animal nature of certain parasites seen in tumors, and especially in carcinoma and sarcoma. He did not claim to have succeeded with inoculation experiments, but was sure of the microscopic appearances. In this publication he gave numerous illustrations of the parasites in the epithelial cells, which, save for a certain coarseness of drawing, would pass muster to-day. He shows, for instance, the parasitic infection of muscle cells, and even their nuclei, with zooglœa spores; and it is impossible to examine his brochure without feeling that he was far ahead of his generation in his recognition of the important rôle played by these animal parasites.

Pfeiffer also set the first example in a careful study of endemic cancer and of localities in which it occurs. He presents a small map of the village of Grossobringen in the neighborhood of Weimar. The little village contains about six hundred inhabitants. During the previous twelve years nearly three times as many had died of cancer as of tuberculosis. He showed that in this small town the mortality rate from cancer was much higher than of the adjoining country or villages. While it cannot be said that he presented a reasonable explanation therefor, this report of Pfeiffer's must still stand as an illustration of topographical study of the most important kind, antedating Behla's similar investigation of the town of Luckau, to which reference has often been made. But I must pass on, lest other matters of importance in this connection be neglected.

Certain observances have been made regarding these parasitic forms, which may be stated somewhat succinctly as follows:

These organisms can be found in regional lymph nodes before epithelial deposits are detected in the same. This would seem to imply that they travel ahead of the epithelial cells, and would seem also to take away the force of that argument which was perhaps put forward first by Rindfleisch, who spoke of the infectivity of epithelial cells. The parasites thus being much smaller may much more easily enter the lymph stream when liberated.

The constant occurrence of young forms of parasite around the periphery of a growing tumor, where they more easily get into both blood and lymph streams, is also of significance, taken with the above. Just how early they make this entrance into the current is a matter yet to be determined, as also whether there is any clinical or pathological sign by which such event may be indicated.

In all cancer cadavers so far examined, we have found organisms in all the organs and even in the peripheral blood, in every instance showing how widely the organisms are thus diffused and the far-reaching effect of a primarily local infection. Also all patients so far examined in whom cachexia has been extreme have given the same result so far as the peripheral blood was concerned. The organisms seem to be always found in this fluid.

Malignant lymphoma is a disease about which in times past no small differences of opinion have existed. This would appear from the variety of names which have been given to it, if on no other account. It certainly presents a great variation in degree of malignancy, some cases being exceedingly rapid and acute, and some slow. In two cases of mine of more rapidly growing type, one of which was fatal without operation, the other undergoing it and resulting in recovery, parasites were found in the circulating blood; in the former instance seven days before death. Such cases as these would seem to be instances of primary lymph or recurring infection. The more rapid in type, the greater the danger and degree of hæmatogenous infection. The slower forms of this kind are commonly those which are usually known as Hodgkin's disease, appearing in its slow type, or at least are barely distinguishable from it. The microscopic changes in the lymph nodes, disregarding changes in the blood, which are seen in malignant lymphoma, Hodgkin's disease, and leukæmia, are barely distinguishable from each other if at all. So too the changes in the spleen in chronic leukæmia, chronic malaria, and splenomegaly (Banti's disease), barring, of course, increase of leucocytes in the former and the presence of malarial parasites in malaria, are barely distinguishable from each other. There seem to be two quite different types of lymph infection—those in which the lymph nodes especially are involved, as in malignant lymphoma and Hodgkin's disease, and those in which the spleen especially is involved, as in the disease last mentioned. The position of malaria at one end of this list and of malignant lymphoma at the other, protozoa being responsible for each of them, would seem to imply that all the intermittent conditions must necessarily be regarded as protozoan infections aside from the actual microscopic findings. In this respect the recent work of Löwit, which is exceedingly suggestive, must not be overlooked.

Those diseases in which enlargement of the spleen forms a prominent feature have been in times past attacked surgically until the number of failures in attempting to relieve lymphatic spleens has led almost to the abandonment of splenectomy for this purpose. The primitive form of splenomegaly (Banti's disease) has given much better result after operation than any of the other morbid conditions of the spleen; and this may now be explained, since in this condition the infection is still local, in whole or in part, and more resembles malignant lymphoma. If leukæmia is a protozoan disease, as Löwit claims, it is on a par with malaria, and must be regarded as a specific infection of blood cells similar to malaria, in which case splenectomy would be very much less promising. It is only when the lymph nodes or spleen are primarily infected, and most conspicuously involved, that the case becomes essentially a surgical one.

Cancer begins as a purely local infection. This is a statement which I have repeated for many years, and which would seem to be verified by our recent work in Buffalo. It kills by becoming generalized. This is also true of tuberculosis, and while there are possible exceptions in each case, the general statement thus made can scarcely be denied. Miliary carcinomatosis is not much more rare than miliary tuberculosis, and these constitute apparent exceptions to the above rule. Even they, however, do not prove that the disease did not have a local beginning. In each case

operation, if done before general infection has occurred, or metastasis has taken place, is exceedingly promising if done thoroughly. This statement, of course, is backed up by universal experience, but finds its explanation in what I have already said. Operations done later are palliative in that thereby a large focus, or dépôt, or principal source of supply is removed, its removal not only lessening danger of general dissemination, but permitting the blood to assert its own normal parasiticidal properties.

More specific illustration of this statement may be found in cancer of the stomach, in which a successful gastro-enterostomy saves the patient from death by starvation, but does not avert his final cachexia and terminal hæmatogenous infection. It prolongs his life only indirectly and for but a short time. On the other hand, radical operation when successfully done seems really to prolong life and to remove cachexia, as theoretically should be the case when the principal source of infection is extirpated.

Take the case again of a successful splenectomy for primary splenomegaly. It at all events produces great temporary benefit, if not indeed absolute cure. It has been hitherto supposed that the splenic enlargement was due to absorption of toxic substances from the intestines. If this were really the explanation, splenectomy would be ridiculous. On the other hand, if the primary infection be in the spleen, and the source of supply limited to that organ, then its removal would be most strongly indicated, and should prove of the greatest benefit. It remains yet to be positively demonstrated that Banti's disease is really a protozoan infection, since I doubt if yet any inoculations of such splenic pulp have ever been made into animals. It is, however, a promising field for research.

If these statements have aught of actual value, this value is extreme, since they should teach that in dealing with primary lymphatic infections of such structures as the spleen and lymph nodes, extirpation done early is of the greatest importance and should not be neglected. It is most indicative also, in my estimation, that in our laboratory experiences Gaylord succeeded just as well when inoculating animals by using old dry lymph nodes as by introducing fresh elements. This suggestion is, so far as I know, original with him, and seems to have a far-reaching importance, that organisms may remain in the dry tissues for considerable lengths of time and still prove effective when inoculated. This is, however, just what we see with vaccine lymph, for instance, while the resemblances between the protozoa of such lymph and those of cancer have been already strongly touched upon.

I want to make it as evident as possible that carcinoma as a type of disease is, in every instance, an example of epithelial infection. Without infected epithelium we have no cancer cells nor cancer formation. Sarcoma, on the other hand, is an infection of connective tissue, probably by the same organisms, the tissue cells reacting somewhat differently. It would seem, so far as we have gone, that different forms of parasite have specific tendencies in one direction or the other; but it will take years of minute and careful study to show which kind of parasite prefers one or the other of these tissue cells. Up to a time within a few years ago, and quite easily within our recollection, malaria was almost as much a mystery as has been cancer. Now we recognize at least three distinct types of malarial parasite, and talk and think of these organisms as if we were reasonably acquainted with them. We have then ample grounds, reasoning by analogy, for supposing that cancer organisms may in some manner manifest specific inclinations. Moreover, those animals which were inoculated with sarcoma showed predominant sarcomatous lesions, although epithelial infection was not entirely wanting. For instance, in the first animal inoculated from my first case, which was so carefully worked up, although the predominant lesion was adeno-carcinoma of the lung, it was nevertheless found that all of the splenic follicles (which are of connective-tissue origin) were likewise infected.

Authentic instances of mixed sarcoma and carcinoma are in man rare clinically; but we may note, for instance, in Cullen's recent work the frequency with which myoma and uterine cancer are associated, and this is made still more apparent by Wadworth's recent paper illustrating the frequent occurrence of these lesions.

An entirely different aspect of this question is still left untouched by our researches, and one to which in time past I have invited your attention, and that is the possibility of spontaneous retrocession, or disappearance of malignant growths. I had thought to get together for presentation to you at this time the views and reports of various surgeons in all parts of the world upon this topic, but was prevented doing this by press of other work. I have for years maintained that in rare instances malignant tumors have undergone a spontaneous and mysterious retrocession, for which it was impossible to account in any known way. While some surgeons have denied that this was possible, others have maintained, as I did, that it has occurred under their personal observation. Most recently in this connection similar instances have been reported by one of our medical confrères, Osler,[1] whom we surgeons always delight to honor. There is nothing in the protozoan theory of cancer which makes this appear less possible or plausible than before, nor is there anything which shows it to be impossible. We see startling recovery from other infections in cases in which hope had been abandoned, and there is no reason to think that such a thing is impossible, even in dealing with so dreadful a condition as cancer.

CONTRACTURE OF THE NECK OF THE BLADDER.*

By CHARLES H. CHETWOOD, M.D.,
NEW YORK,
PROFESSOR OF GENITO-URINARY SURGERY AT THE NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL; VISITING SURGEON TO BELLEVUE HOSPITAL.

In treating the subject of contracture of the neck of the bladder, the literature of which is limited and obscure, this paper will encroach upon the prolific and more discussed subject of prostatic hypertrophy—first, because these two maladies have much in common and have been more or less confounded, and second, because one of the purposes of this writing is to introduce as a substitute for the Bottini galvano-caustic operation a more surgical procedure, the claims of superiority of which are based upon such advantages as greater precision, lower mortality, fewer complications, and the promise of better results.

Such unstinted praise, appearing as it does at the opening of an article, would seem fulsome indeed were it not sustained by the practical showing of a fair array of clinical cases to be hereafter reported.

This same malady has been described by different writers under various designations. In a thesis embodying this subject ("De la contracture douloureuse du col de la vessie"), Sockell[1] undoubtedly has in mind the condition under present consideration, but does not give a definition which conveys a clear understanding of its real nature and cause.

Some early writers describe contracture of the vesical sphincter under the denomination of neuralgia (névralgie du col), while others have embraced it in a

[1] American Medicine, vol. i., p. 65, April 13, 1901.

* Read before the Association of Genito-Urinary Surgeons, May 2, 1901.

description of chronic cystitis of the neck of the bladder, and the same morbid condition has been described under such titles as spasm of the neck of the bladder, "valvule," urethro-vesical fold, barriers, etc.

Civiale,[2] one of the earliest writers upon this condition, recognizes a simple urethro-vesical fold of mucous membrane in some cases and in others a more dense barrier containing fibrous or muscular tissue.

Mr. Guthrie[3] mentions chronic thickening of the neck of the bladder, and enumerates symptoms of this

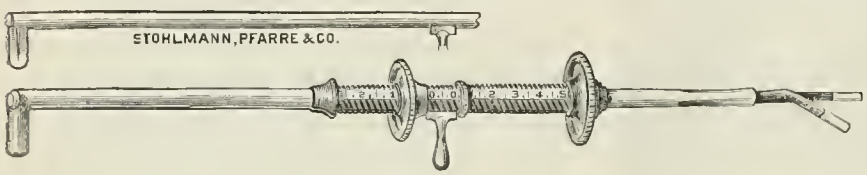

FIG. 1.—The Author's Original Perineal Galvano-Cautery Incisor.

condition, which are those peculiar to most cases of contracture.

Mercier[4] speaks of the existence of a urethro-vesical barrier produced by muscular spasm, the result of prolonged irritation.

Fuller[5] describes the condition of "chronic contraction of the prostatic fibres encircling the vesical neck," and likens this lesion to the tonic contraction of the sterno-mastoid muscle in torticollis.

Von Frisch[6] says: "In long-standing cases of spasm of the sphincter there results an inability to empty the bladder entirely, and there may arise from this a permanent insufficiency of the bladder muscle with residual urine amounting to from 100 to 250 c.c. and more." These somewhat varied opinions, representing different theories of writers whose views are entitled to recognition, while not entirely in accord, refer to either the same condition or to different degrees or phases of the same malady.

Definition.—What is meant in this paper by contracture of the neck of the bladder is a fibroid stenosis of the vesical sphincter or fibrous infiltration of the glandular and muscular tissues encircling the bladder neck, simulating symptomatically stone in the bladder and resembling senile prostatic hypertrophy by the mechanical hindrance it produces to the urinary outlet. Many of the cases of prostatic hypertrophy reported are simple cases of contracture, notably some of those operated upon by the Bottini method, or are of the contracture type of prostatic hypertrophy in that they present a fibroid collar at the vesical orifice, which contains more or less adenomatous tissue, and this condition may and does exist alone or in combination with central, unilateral, or bilateral prostatic outgrowth.

Cause.—The cause of this pathological condition is found in long-standing chronic inflammation centred in the region of the trigone (behind) or in the prostatic sinus (in front). It is commonly but not necessarily of gonorrhœal origin. Prostatic abscess, stone in the bladder, traumatism, or any of the conditions involving prolonged suppuration in the neck of the bladder or prostatic urethra may leave behind them this condition; and it may also coexist with prostatic hypertrophy, when it becomes one of the elements of the obstruction formed by this morbid growth.

Sir Henry Thomson[7] in his writings on diseases of the prostate recognizes the existence of this organic obstruction apart from that caused by prostatic hypertrophy. In his conclusions he states:

"That an organic obstruction may exist at the neck of the bladder when there is no enlargement of the median portion of the prostate.

"That in this case it is most commonly due to hypertrophy of the muscular fibres at the neck of the bladder produced by long-continued irritability of the viscus and generally occasioned by stricture of the urethra, inflammation or calculus of the bladder, and occasionally appearing without any of these conditions.

"And that sometimes the obstruction consists of a fold of mucous membrane and submucous tissue drawn upward by enlarged lateral lobes of the prostate, the median portion being slightly, but sometimes not at all, affected."

An example of the latter condition may be found in Case XII. operated upon by the writer.

Symptoms: The symptoms of contracture of the neck of the bladder, as already stated, are analogous to those of vesical calculus. The most predominant symptoms are urgency and frequency of urination, the calls to urinate varying from half-hourly to every two hours day and night. The desire is generally precipitant, and if not responded to promptly is productive of marked pain in the bladder region or involuntary urination. Difficulty in starting the flow is noted in some cases, and attacks of complete retention supervene in many instances. In long-standing cases the force of the stream is distinctly less than normal, and residual urine exists in varying quantity in most if not in all cases. As is the case in prostatic hypertrophy the urine generally contains the elements of catarrhal inflammation, while at times it is devoid of these qualities and is perfectly clear. Examination per rectum discovers nothing characteristic of this condition, although, as stated, prostatic hypertrophy may coexist. Examination by way of the urethra with a short-beaked sound meets an obstruction beyond the prostatic sinus, and after entering the bladder, the same obstruction will be recognized by turning the beak toward the bas fond. The urethral distance is not elongated unless there be a coexistent median or lateral prostatic enlargement.

Treatment.—The treatment of this condition, if intended to be radical, must necessarily be directed toward the removal of the existing obstruction to the urinary outflow. Such methods as forced dilatation and cauterization have been tried, and yield at best only temporary and transient relief of the affection and cannot be treated as worthy of consideration. The only satisfactory surgical means of attacking it, which has been tried and has accomplished the end in view, is free incision of the obstructing area through a perineal wound. Perineal cystotomy was performed a long time ago under the inspiration of Mercier, who was one of the first to conceive the idea of cutting down the neck of the bladder through the urethral channel by means of a specially devised instrument. But the complications and difficulties attending such an operation are similar to those met in connection with the Bottini galvano-caustic operation, among which may be mentioned hemorrhage, painful and prolonged bladder spasm, complete retention of urine, swollen testicle, prostatic abscess, and profound urinary infection. All of these dangers are very much lessened, if not removed, when a perineal opening is made and drainage instituted.

The Bottini operation, which was introduced some twenty-five years ago by the author whose name it bears, was advocated as an improvement upon the Mercier urethral prostatotomy, and was intended to lessen the danger of hemorrhage and to produce a more permanent result. That an incision made by means of a galvano-caustic knife is less prone to be followed by hemorrhage, and more likely to leave a permanent channel, appeals to reason; but it cannot be denied that, when conducted through the urethra, it is accompanied by all the other disadvantages at-

tending the same operation without the cauterizing element. One of the greatest objections to an intravesical operation done by way of the urethra is the lack of precision allowed in its performance. Recognizing this difficulty, there has been introduced of late an instrument permitting the Bottini operation to be performed under ocular inspection by the combination of a cystoscopic attachment to the incisor. But who can read the many contributions to the literature upon the subject without being impressed with the number of complications and difficulties which have occurred in connection with the Bottini operation even when performed by the most skilled hands? Taking into consideration the difficulties encountered during and after its performance, and recognizing that its advantages are such as can be incorporated in an operative procedure which is surgically precise, less dangerous, and more effectual, who will deny that such an operation is entitled to the honor of precedence?

This operation consists in adopting the perineal route as a means of approach to the neck of the bladder, and the galvano-cautery knife as a means of removing the obstruction or the obtruding inflammatory or hypertrophied outgrowth.

W. T. Belfield,[8] of Chicago, in 1886 reports two cases of prostatic hypertrophy operated upon by a technique which consisted in making a perineal wound and in applying the electric cautery through this opening to the enlarged prostate. In one of these cases the cauterizing operation was performed two weeks after a perineal drainage had been established, and resulted in a decided diminution of the symptoms up to the time of death seven months after the operation. The other case was unsuccessful on account of the failure of the battery.

F. S. Watson,[9] of Boston, in his admirable monograph on the operative treatment of the hypertrophied prostate, published in 1888, describes an instrument devised by him, called a galvano-cautery prostatectatome, for the purpose of attacking the enlarged prostate through a perineal wound or a suprapubic cystotomy. He describes this instrument as having the form of a short, broad-bladed lithotrite, the blades of which are reduced to a thin edge by a large central fenestra. Each blade contains a platinum wire loop connected by conducting wires through the inner shaft with a battery which affords the electric current. This instrument is intended to grasp a central portion of an enlarged prostate for its removal or to extirpate the gland piecemeal. No cases are reported. It will be seen that in both the above instances there is a lack of sufficient clinical material to demonstrate the value of the operation suggested, although it resembles that employed by the writer of this paper. This method is a modification of the Bottini technique. A specially constructed instrument performs the same function as the galvano-cautery knife of Bottini, but is operated through a perineal opening.

Instrument.—The first instrument constructed, and used by the writer thus far in the greater number of his cases, has been found quite satisfactory as regards principle, but has since been embellished and rendered more wieldy. Like the Bottini and Freudenberg instruments, there is an outer shaft in which slide the wires and cautery knife. The beak is turned to a right angle. The blade is about 1 cm. in length. The handle of the instrument is graduated so that the length of the cut is accurately determined. The sliding of the knife is controlled by the fingers instead of by the rotation of a wheel, so that the operator more readily appreciates the density of the tissues and the progress of the blade during cauterization. A movable stop upon the handle makes it impossible to cut beyond the distance determined upon before the current is turned on. One hand only is required to operate the instrument, so that the index finger of the other is free to be introduced in the rectum. No cumbersome cooling attachment is required. The circulation of a cold sterilized solution through the urethra, and out through the perineal wound, accomplishes the purpose of keeping the instrument sufficiently cool without affecting the blade. When a storage battery is used an amperemeter is attached, and the same amount of current is required as with the Bottini instrument—namely, about 50 amperes. When the street current can be had, which is much more satisfactory, a motor transformer and rheostat are needed. Fig. 1 shows the author's original incisor and Fig. 2 a later instrument with improved attachments. The older instrument is intended to be held in the hand against the web between the index finger and thumb, as the battery wires are attached behind the handle and run off horizontally. The new instrument is supported against the palm of the hand, the battery wires running off perpendicularly, and there has been added a cut-off, under the control of the fingers of the operator, which the original instrument did not have.

Operation (Fig. 3).—The patient is placed in the lithotomy position, the bladder having been previously washed with boric or boro-salicylic solution, a small portion of which is left in the bladder. If it has not already been done, the urethral distance and amount of residual urine should be noted. A small-sized grooved staff is introduced and a median perineal incision made upon this, opening the membranous urethra. The bladder having been reached, the staff is withdrawn and the finger introduced into the perineal opening. In cases of marked contracture of the neck of the bladder, whether accompanied by prostatic hypertrophy or not, when the vesical orifice is too small to admit the examining finger, this opening is not forced and torn by the finger of the operator, but the cautery knife is at once introduced for the first incision. In making this cut it is not necessary to be particular that the bladder contains fluid. The instrument is first tested and then introduced in the bladder through the perineal opening. The index finger of the left hand feels for the beak through the perineum. An assistant couples with the meatus a blunt glass nozzle attached to an irrigator containing cold saline or boric solution. The operator, who holds the handle of the incisor in one hand and recognizes its actual situation with the finger of the other in the rectum, turns on the current by means of the interruptor, and the assistant allows the cooling solution to flow. Ten seconds are allowed to lapse before the

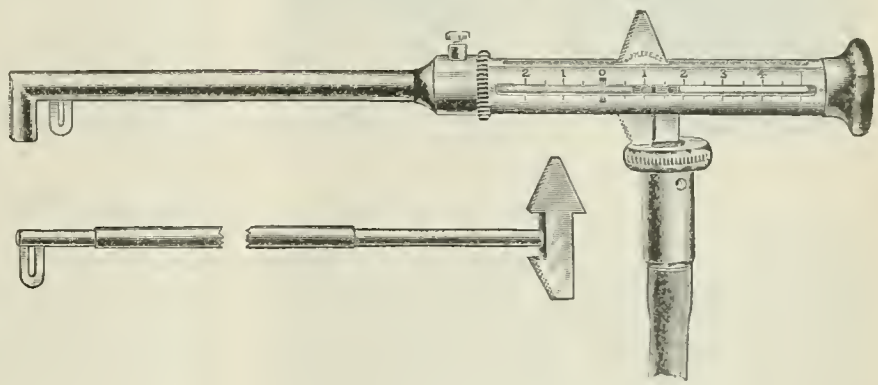

Fig. 2.—The Author's Improved Instrument.

knife is unsheathed. The operator then slowly withdraws the knife with the fingers of the right hand, readily appreciating that it is doing its work. This manœuvre is conducted very slowly. From one-half to three-quarters of a minute is generally taken to complete an incision of minor length and return the knife to the sheath, when the current is discontinued. The cooling irrigation is allowed to flow for a short time, and the instrument is then withdrawn. The finger of the operator can now readily enter the bladder and a careful and exact examination be made. In cases of simple contracture the work has been completed, as is often also the fact when there is a prostatic bar. When the finger distinguishes a marked unilateral or bilateral prostatic growth, these are either carefully burned through with the galvano-cautery knife, or in the case of a pedunculated lobe its removal is effected by means of an incision on either side. The bladder is now washed and a small perineal tube tied in place.

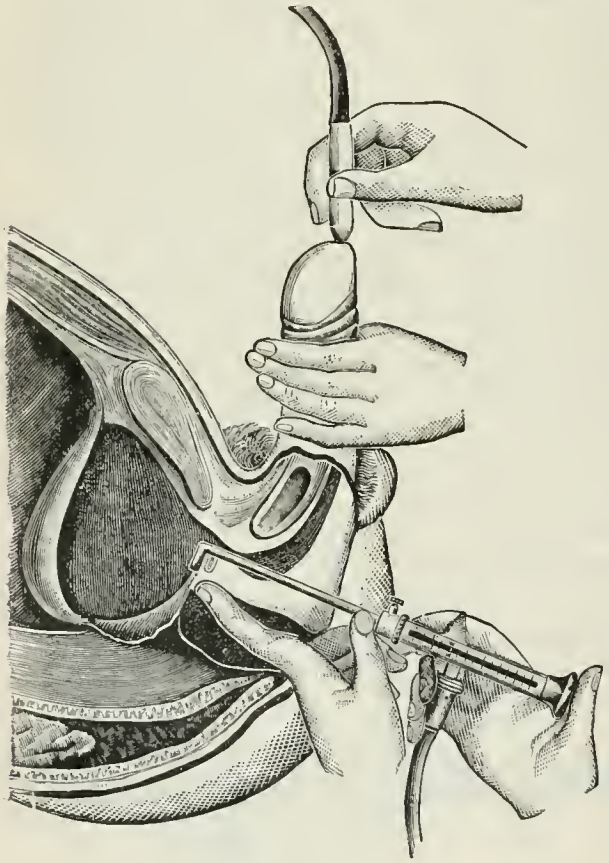

Fig. 3.—The Operation.

The patient is returned to bed, the whole operation having taken but a few minutes after he is under the influence of the anæsthetic. General anæsthesia is always employed, beginning with nitrous oxide and ending with ether. If the patient's kidneys are diseased, or if for any other reason chloroform is preferred, after the ether anæsthesia has been thoroughly established chloroform is substituted, and thus a minimum amount of the former anæsthetic is employed. The advantages of general anæsthesia need no comment. Those who have done the Bottini operation often seem to prefer its use, and the patients themselves demand it.

The after-treatment of the patient is important, and is practically the same as that employed for perineal section. Urotropin or cystogen is given in doses of gr. xl.–l. in twenty-four hours, and an anodyne may be administered, but is seldom required. The bladder is washed daily with boro-salicylic or nitrate-of-silver solution through the perineal tube. The bleeding is always slight. In none of the cases operated upon has it been persistent or annoying. The perineal tube is removed from the third to the sixth day, after which the re-establishment of the natural channel takes place, as after a perineal section, at the expiration of a variable period.

Sixteen cases have been operated upon by the writer. The ages of the patients have varied from thirty to seventy-three years, six of them being below the age of forty-five, and the remainder between forty-five and seventy-three years old. Six patients (i., v., vii., viii., ix., xi.) were cases of simple contracture of the neck of the bladder. Three patients (iv., x., xiv.) had reached the age when prostatic hypertrophy supervenes, and might aptly be called cases of the contracture type of hypertrophied prostate without marked lateral enlargement, and, besides these, five patients (ii., xii., xiii., xv., xvi.) had more or less unilateral or bilateral prostatic outgrowth. One case (ii.) was complicated with calculi. Two cases (iii., vi.) were tuberculous. Two patients (xiii., xiv.) had previously had epicystotomy performed, in one of which a suprapubic fistula remained. Two patients (i., v.) were diabetic. Out of this number there had been one death (xvi.) which occurred five weeks after the operation from pyelonephritis, the patient having secreted prior to the operation only 10 to 13 gms. of urea in twenty-four hours. Seven (i., ii., v., viii., x., xi., xv.) patients may be considered entirely cured; three (vii., xii., xiii.) are materially improved, and five (iii., iv., vi., ix., xvi.) partially improved.

In regard to those cases reported as being partially or materially improved, two of them are tuberculous, and these obtained no further benefit from the operation than what might be expected from ordinary perineal drainage, although the intensity of their symptoms has somewhat moderated, and the intervals between urination are slightly lengthened. The remainder of these improved cases are still under observation, and show signs of progressive betterment.

There is no evidence of permanent perineal fistula in any of the cases operated upon. In one only (iv.) has there been much tardiness in the closure of the wound. The cases (xiii., xiv.) complicated with suprapubic fistula resulted in complete closure.

There existed in all of the cases more or less residual urine, and in several there was urinary overflow, with the bladder retaining between seventy and seventy-five ounces.

The symptoms of urgency and frequency of urination, diurnal and nocturnal, were present to a greater or less degree in every instance, and, as a result of the operation, have disappeared or moderated in most of the cases.

The residual urine has entirely or practically disappeared as a result of the operation in all cases with the exception of one (xiii.), in which there still remains four ounces, there having been at the time of the operation thirty ounces of retained urine, and the residuum has shown evidence of progressive diminution at each examination subsequent to the operation.

Two of the patients (ix., xiv.) still under observation have more or less incontinence of urine, but as this is at times materially diminished, it is hoped that it will ultimately disappear.

Two patients (iv., ix.) developed after the operation swollen testicle, both of whom had previously had similar attacks of the same trouble. There was no suppuration either in the testicle or the ducts, the inflammation promptly subsiding under appropriate treatment.

In reviewing the histories of the foregoing cases, a noteworthy fact is the absence of complications which have been a feature in many of the operations performed according to the Bottini technique, as admitted by the various writers who have reported them.

One of these complications, perforation of the urethra by too long an anterior incision, has occurred in the experience of most operators who have employed the Bottini method, and, according to Meyer,[10] is more likely to happen in cases of the so-called soft variety of prostatic enlargement, on account of the impossibility of determining prior to the operation the compressibility of the tissues, and, as Meyer states, "unforeseen occurrences may then baffle the operator." To use his language, "for if, in the case of a fibrous prostate with lengthened urethra, he should exhaust the full length which the ordinary incisor permits of cutting, namely, 4 cm., the incision may easily be too short, and never properly divide the obstruction down to the prostatic urethra—an experience which I have had in a few cases—or if in a soft, compressible gland he should made an incision of from 2.5 to 3 cm. in length, he may at once do a real internal posterior urethrotomy and perforate the urethra, an accident that happened to me in two instances."

Granville McGowan[11] met with a similar unfortunate experience during the operation upon one of his patients, although a proper amount of precaution and gentleness was exercised; the patient died, having developed perineal abscess.

L. Bolton Bangs[12] reports two deaths due to acute sepsis. In one of these cases he states that the posterior incision probably opened the deep urethra.

Freudenberg, Meyer, and Granville McGowan all report cases of perforation of the space of Retzius by the anterior incision, which on this account has been discarded.

These are the complications which have been met during the performance of the Bottini operation, and it is obvious that with the perineal wound, through which the operator's finger can determine the compressibility of the tissues and the actual distance to be traversed by the cautery knife, the danger of these complications does not arise, and even if the anterior incision be long enough to encroach upon the urethra, with the drainage afforded by the perineal wound and the introduction of the tube it can do no damage.

With regard to the post-operative complications, the most dangerous of which are urethral fever, profound sepsis, and pyæmia, the existence of adequate drainage is certainly the most surgical means of guarding against such conditions as these, as well as the annoying occurrence of absolute retention, frequent and painful bladder spasms, and hemorrhage, which have characterized the histories of some of the cases operated upon by the Bottini method.

Those uncompromising advocates of the Bottini operation who oppose this modification will do so on account of the perineal incision employed; but how can such an objection stand in the face of its many advantages? Others may say that when an incision is made one might as well perform the more radical operation of extirpating the gland by means of a complete prostatectomy. In this particular the observations of F. S. Watson[9] are of interest. In examining the anatomical specimens of thirty cases of prostatic hypertrophy this writer found that in twenty-one out of the thirty, or more than two-thirds of the number, the median enlargement could have been successfully reached and incised, or partially or wholly removed, through the perineal route; and in seven cases the great distance of the median enlargement from the perineum rendered the suprapubic operation imperative, if any were done.

I can do no better than to quote from the conclusions of this writer at the end of his thesis: "In a given case open the membranous urethra, put in your finger and explore. Twice out of three times the operation can be completed by this route. In the other third of the cases the long perineal distance, or the form of the median enlargement, will make the suprapubic operation necessary."

The most ardent advocates of the Bottini technique admit that some cases are not suitable to this mode of procedure, and should be submitted to the more radical method of prostatectomy. Yet it has not been shown how to determine previous to operation upon a given case which method should be adopted. Cystoscopy is of doubtful expediency in advanced cases of prostatic hypertrophy, especially when there is evidence of pyelonephritis. Meyer relates a case in which cystoscopy was followed by protracted urethral fever that ended fatally.

The finger is much more serviceable in solving any and all the questions which may arise in doubtful cases.

A perineal incision permits an exploration, which is better and more rapid than cystoscopy, affords opportunity for an operation, based upon the Bottini technique, with the most absolute precision, which the Bottini method lacks, while if this operation be deemed insufficient or improper in a given case, the total extirpation of the hypertrophied prostate gland, either by the perineal or suprapubic route, can be accomplished.

It remains for future experience to develop how permanent are the results obtained in this somewhat varied collection of cases, and for other surgeons who may test this operation to define its limitations.

Report of Cases.—Case I.—J. H——, aged forty-five years. The patient has had chronic urethral discharge for over ten years, during which period he had several acute exacerbations. He has been troubled with too frequent urination for about one year. This difficulty came on slowly, and has progressively increased so that at the present time he rises from three to six times during the night and urinates every hour by day. The desire to urinate comes on suddenly, and is imperative. The urine is filled with pus, and examination reveals an excess of urates, acid reaction, a small percentage of albumin, and evidences of hyperæmia of the renal pelvis. The patient, having been submitted to various therapeutic measures without improvement, was prepared to accept surgical interference. Examination finds no peripheral prostatic enlargement per rectum; a dilated prostatic sinus and a bar at the neck of the bladder; urethral length seven inches; residual urine half an ounce.

Operation, November 20, 1900, median perineal cystotomy. The finger detects a very marked contracture of the neck of the bladder, which is burned with the galvano-caustic knife a little to the left of the median line at a slight angle 1 cm. in length. In this case the Freudenberg-Bottini instrument was used, and, the first cut being unsatisfactory, a second had to be made in the same line. Little reaction and a mild amount of bleeding follow. The perineal tube is removed at the end of six days. The wound closes satisfactorily, and the patient leaves the hospital at the end of three weeks with a small amount of dribbling between urination. At the end of six weeks after the operation the patient sends his urine for examination. The albumin has entirely disappeared; there is no evidence of renal hyperæmia; it is perfectly clear, and entirely free from pus and shreds. He reports that he urinates every three hours by day and once or twice at night. There is still some dribbling. Four weeks later the patient sends another specimen of urine, which is entirely clear, free from albumin, and contains no pus. The intervals between urination run as long as four or five hours, and he can pass the night without rising. There are only a few drops of dribbling between the urinary acts.

Case II.—November 27, 1900. H. L——, aged fifty-eight years, has had frequent urination for twelve

or fifteen years past, which came on gradually and increased progressively. For the first six years of this period he was compelled to rise two or three times at night and in the last six years five or six times ordinarily. In the past few months, however, his condition has been much worse; urination has been from every five minutes to every half-hour day and night, and is accompanied by intense pain, notably at the end of the act. Exercise and exertion of any kind intensify his symptoms. The urine is markedly purulent and ammoniacal. He has been treated at the hands of his family physician with bladder irrigation, and has had between two and three ounces residual urine. No improvement has attended this treatment. There is a small amount of blood squeezed out with the terminal urine. The patient's suffering is so great that no exploration is deemed advisable, a tentative diagnosis being made of prostatic hypertrophy with possible calculus. He is prepared for operation on the following day.

Operation. Examination of the patient under the anæsthetic results in finding the prostate per rectum moderately enlarged; the urethral length is not taken; residual urine three ounces. Median perineal cystotomy. Two small calculi, weighing ten and twelve grains, are found and removed with a bladder scoop. There is a left prostatic enlargement and a moderate median bar. The left lobe is incised with the galvano-cautery knife at a slight angle, so as to accomplish sufficient lowering of the median bar. A perineal tube is inserted; no reaction and little hemorrhage follow. The patient experiences immediate relief from all symptoms following the operation. The tube is removed at the end of six days. The patient leaves the hospital and returns home at the end of three weeks. He urinates about every hour day and night, and has a certain amount of dribbling between times.

February 11th. The patient urinates twice in the forenoon and two or three times in the afternoon; rises once or twice at night; has absolutely no pain, no leakage, no residuum. The urine is free from pus, and contains only a few shreds. The patient considers himself perfectly well.

Final report, April 24, 1901. The patient urinates about every four hours by day and rises only once at night, and sometimes not at all. There is no leakage, and the urine is free from catarrhal elements.

Case III.—December 15, 1900. G. K——, aged thirty-three years. The patient states that when twenty-five years of age one evening he tried to pass water as usual, but was unable to do so on account of, he says, clots of blood in the bladder. There was no cause assigned for this condition, he having been attending to his regular occupation previous to the occurrence. His bladder was washed at the time by his physician, and soon after he enjoyed his usual good health, with no signs of blood in the urine until two years later, when he again noticed the presence of blood in the urine. Two months later he had a third attack of hæmaturia, and thereafter his attacks became more frequent; first every couple of weeks, then every week, then every day. As the attacks of hæmaturia became more frequent, the desire to urinate also increased, and was accompanied by intense pain, which was absent when the hæmaturia first occurred, and until the last few months.

Operation, December 18, 1900, perineal cystotomy. There is a contracture at the neck of the bladder, but it is soft, non-resistant, although barely admitting the tip of the index finger. Incision is made with the galvano-cautery knife, about 0.5 cm. in length. No reaction from the operation and little bleeding follow. The patient is up and about at the end of three weeks, there having been no return of the hæmaturia. The perineal wound was somewhat tardy in healing, but finally closed entirely. The patient's urinary symptoms are slightly but not materially improved since the operation. Before the operation he had been compelled to urinate about every fifteen minutes by day and about ten times at night. At present (twelve weeks after the operation) he urinates ordinarily from every one-half to three-quarters of an hour day and night. Sometimes in the early morning he goes as long as two hours. An examination of this patient's urine prior to the operation revealed the presence of tubercle bacilli and the evidences of pyelo-nephritis.

Case IV.—J. S——, aged fifty-two years, had gonorrhœa about twenty-eight years ago, which, he says, lasted about eight months; had a second attack last July. For the past five and a half years he has been compelled to arise once or twice to urinate, and has had some frequency by day. This condition continued until December last, when he noticed a burning pain along the urethra, and was compelled to arise three or four times at night to pass water. He entered the hospital January 31, 1901. Residual urine, one-half ounce; no appreciable enlargement of the prostate can be felt per rectum. The searcher detects a barrier as it passes over the prostatic urethra and enters the bladder.

Operation, January 10th, perineal cystotomy. The finger through the perineum recognizes the bar at the vesical outlet. One incision is made slightly to the left-hand side with the Bottini instrument.* There are no reaction and no bleeding after the operation. The tube is removed at the end of five days. The patient walks around the ward at the end of three weeks, and complains of more or less continuous dribbling of urine between the urinary acts, when upon his feet. He leaves the hospital at the end of a month, and returns in three or four days with a swollen testicle on the left side without apparent cause. One week later, when the left epididymitis had subsided, his right testicle also swelled. The patient reports having had several previous attacks of the same trouble. Both testicles yielded to the ordinary treatment, but the incontinence continued. About eight weeks after the first operation, there being no cessation in the continued tendency to incontinence, it was thought an inadequate cut might have been made, and a second operation was proposed. Operation February 7th. The same procedure is repeated, but the specially devised galvano-cautery knife is employed. When the perineum is opened, the index finger finds still some contracture at the vesical orifice, but in lesser degree than before the previous operation. The patient has some febrile disturbance after the second operation, but no hemorrhage; he sits up in bed in two weeks, and walks about the ward at the end of three. The perineal wound is sluggish, and some of the dribbling passes by this route.

April 25, 1901. The patient urinates every three hours by day and about four times during the night. There is still some dribbling of urine through the penis and through the perineal wound.

Case V.—E. S——, forty-five years old; January 5, 1901. Four years ago the patient had gonorrhœa for the first time. This lasted for nine weeks. During the fourth week of this attack he had hæmaturia, which lasted four days. Last October he developed a slight discharge, which disappeared in three weeks. At the same time he passed blood at the end of each urination. The calls to urinate are, and have been in the last eight weeks, frequent and urgent, and the discharge of blood with each urinary act has continued up to the present time. The patient has also diabetes.

Operation, January 10, 1901, perineal cystotomy.

* This was one of the first operations performed and a special instrument was not in use. From lack of experience an insufficient amount of current was employed.

The neck of the bladder is tightly contracted, and is incised with galvano-cautery; no reaction follows. He is discharged from the hospital at the end of three weeks. The patient disappeared from observation until March 25, 1901, when he reports himself as being well. He urinates every three or four hours by day and rises sometimes once at night to pass the water, and sometimes not at all. There is no pain in connection with urination, and he has gained in weight and strength. The urine is clear.

Case VI.—E. S——, aged thirty-one years; January 10, 1901. When twelve years old, the patient states, he sustained serious internal injury, the result of a fall from a horse, following which he passed small clots of blood, and continued to do so for one year afterward. Subsequently he enjoyed good health up to four years ago, when, after a severe exposure to cold, he was confined to bed, with night sweats. At this time he again noticed the passage of blood in the urine, sometimes in clots and sometimes fluid. On the 30th of June last he was operated upon for a supposed stone in the kidney, but none was found. At that time perineal section was performed and a perineal tube inserted. Following these operations the patient thinks he was worse than before; the calls to urinate are almost continuous, and are accompanied by intense pain before, during, and after the act. Physical examination reveals dulness over the left apex and tubular breathing. Examination of the sputum reveals a few tubercle bacilli.

Operation, January 12th, perineal cystotomy. A moderate contracture of the neck of the bladder is found and is incised with the galvano-cautery knife. The bas fond is covered with velvety granulations, which are scraped away with a blunt curette. The patient suffers considerable pain the first few days after the operation. The calls to urinate are from every hour to every half-hour, and accompanied by great pain. One week after the operation the urine passes almost entirely through the penis. The intervals of urination have slowly lengthened, and the pain is materially decreased. A second exploration is made under the anæsthetic two weeks after the first operation, and the finger introduced through the perineal wound finds the neck of the bladder in good condition. The floor is again curetted with a dull scoop. Following this secondary operation the perineal wound again heals; the urine comes from the natural route at the end of three days. The intervals are about every half to three-quarters of an hour. The pain has lessened, but still continues to be annoying. The patient leaves the hospital at the end of about ten days, somewhat but not satisfactorily improved.

Case VII.—J. G——, aged thirty-three years, was admitted to the hospital January 8, 1901. The patient complained that for a number of years the calls to urinate had been frequent and urgent. He had contracted gonorrhœa sixteen years previously, when he was placed under treatment, but apparently not thoroughly cured. In the last six years he had been compelled to arise at night to pass water six or seven times. The stream has become small, and at times the urine passes in a dribbling manner. The patient was taken sick two or three months ago with sudden chills and sweating, which caused his confinement to bed. At present he complains of deep-seated pain in the perineum, of a bearing-down character, aggravated by sitting down. An examination per rectum reveals an enlargement and fluctuation in the prostatic region.

Operation, January 14th. Residual urine, two and one-quarter ounces. The perineal incision opens a large prostatic abscess. There is a very pronounced contracture of the neck of the bladder, which is incised with the galvano-cautery. No reaction from the operation and little hemorrhage follow. January 20th, the patient is allowed to sit up, and has no elevation of temperature. He is placed on regular diet. January 25th, the perineal wound has almost healed. A moderate amount of urine still escapes, but most of it is passed by the penis. The patient gets up once or twice at night to urinate, and the intervals by day are about half-hourly. February 5th, the perineal wound is closed up; the urinary calls are urgent, and there is some dribbling. February 18th, the patient is discharged at his own request. The frequency of urination has materially diminished, and there is no dribbling. He urinates two or three times during the forenoon and afternoon and about the same during the night.

Case VIII.—G. C. H——, aged twenty-nine years. January 21st. The patient comes complaining of frequency and urgency and precipitancy of urination, which symptoms have existed for over a year. He has also pain during and after the urinary act. Exercise aggravates his symptoms. He had gonorrhœa three times; the first attack eleven years ago, which persisted for two years, at which time the posterior urethra was involved; he had relapsing attacks from time to time up to two and a half years ago, when he had what he considered to be the third gonorrhœal attack. His present condition has been more or less continuous since this last attack, but the symptoms have been much more marked in the last year. He now urinates three to five times at night, and from every hour to every two hours by day. The urine is clear in the second flow and purulent in the first. There is a stricture at four and one-half inches, admitting a No. 17 French bougie. There are two ounces of residual urine.

January 22d, operation, perineal cystotomy. There is a pronounced contracture of the neck, which will not admit the finger. A left lateral cut at an angle of about 45° is made with the galvano-cautery knife. The anterior stricture is cut. There is little reaction from the operation, and no hemorrhage follows. The tube is removed January 24th. He has some difficulty in retaining his urine subsequent to the operation up to February 20th, when the perineal wound has practically healed, and the urine is controlled more satisfactorily. March 4th, the patient is discharged from the hospital. He passes water every five hours; has no complaint, with the exception of a slight discharge from the meatus. March 28th, the bladder now empties itself perfectly. He urinates every three to five hours by day, and does not habitually rise at night. There is slight dribbling at times, but this is not constant, and is growing gradually less.

Case IX.—January 25, 1901. P. A. P——, aged thirty-nine years, complains of bladder trouble fifteen years old. He now urinates every two or three hours by day and twice or three times at night ordinarily, but more often much more frequently. The residual urine found at this examination is three drachms. The patient states that the residuum is often much greater than this quantity, being sometimes several ounces. He has been subjected to treatment by deep instillations and sounds and injections, and has had acute attacks from time to time brought on by treatment.

Operation, January 29th, perineal cystotomy, which reveals a pronounced contracture of the bladder neck. A lateral incision is made by means of the galvano-cautery knife a little over 0.5 cm. in length. No reaction or hemorrhage follows. The tube is removed at the end of a week. After removal of the tube the patient suffers more or less from bladder spasm, and a catheter is tied in the urethra for three days. This is followed by left epididymitis, the patient having had several previous attacks of the same trouble. He

leaves the hospital at the end of four weeks, and starts for his home on the Pacific coast at the end of five weeks. He urinates every three hours by day and rises twice at night. There are still some pain at the end of the urinary act and a very slight amount of dribbling at times.

Case X.—E. R——, forty-six years old. January 31, 1901. The patient has had cause to complain of his bladder for about ten years. He urinates hourly day and night. At times he has been compelled to rise as often as fifteen times during the night. He disclaims ever having had venereal disease. After passing two ounces normally, ten ounces of residual urine is drawn, which is perfectly clear, and contains no pus and no shreds.

Operation February 5th, perineal cystotomy. There is a dense fibrotic bar at the neck of the bladder, which is incised with the galvano-cautery. There is no hemorrhage, no disturbance, or reaction. Size of cut 1 cm. The removal of the perineal tube, at the end of four days, results in a rise of temperature and symptoms of systemic infection. The tube is reinserted after being out three days and left in four days longer. There is a slight elevation when the tube is again removed, but this gradually subsides, and normal conditions hold after a few days. The residuum at the end of two weeks is but one ounce. This is gradually reduced until March 3d, when he leaves the hospital, there is none. He urinates about every three to four hours in the twenty-four, but states that he could hold the water longer if he tried. The urine is purulent, but not offensive. March 30th, he now urinates three to five times by day, and can go the night through with emptying the bladder but once; there is no residuum. The urine is still somewhat cloudy, but gradually clearing.

Case XI.—E. H. B——, aged thirty-nine years. February 14, 1901. The patient complains of trouble with his bladder. He urinates with variable frequency, from every five minutes when moving about, to every three hours when quiet. He urinates from five to eight times at night. There is pain during the act of urination, which is also variable, and is intensified by exercise. He has at times voided blood with the urine, the greatest amount having been after some unusual exertion. His trouble, he says, has been most marked in the last two months, but he has been compelled to rise two or three times at night for the last seven or eight years. He denies venereal history. There is no tuberculous family history. The prostate is inflamed and enlarged, not very tender; the urine is turbid, purulent, and slightly blood-stained. There is one and one-half ounces of residuum. Search for stone is negative. There are a rigid bar at the neck of the bladder and a long prostatic sinus. A gush of fresh blood follows the withdrawal of the searcher. The capacity of the bladder is five ounces; the urethral length, eight inches.

Operation, February 15th, perineal cystotomy. A marked contracture, barely admitting the tip of the index finger, is incised with the galvano-cautery knife. A perineal tube is inserted. No reaction and little hemorrhage follow. The tube is removed at the end of one week. The patient leaves the hospital and returns home at the end of three weeks.

Case XII.—H. W——, aged sixty-four years. February 20, 1901. The patient has had three attacks of gonorrhœa, the first of which occurred when he was eighteen years of age, and the last three years ago. For the past seven years he has had marked urgency and frequency of urination, having been compelled to arise once or twice during the night for the first two years, since when there has been a marked increase in the intensity of the symptoms. In the past five years there has been more or less constant dribbling of urine. At the present time he is compelled to make his water twelve to fifteen times during the day and eight to ten times at night, but little urine being voided at each time, and that only by a straining effort. He has had several attacks of retention of urine. The prostate per rectum is bilaterally and symmetrically enlarged and of dense consistency. The urine is alkaline in reaction, 1.016 specific gravity, and contains no albumin or sugar.

Operation, February 22d. The patient is catheterized and forty-seven ounces of retained urine is drawn. The urethral length is seven inches. A median perineal cystotomy is performed. The finger introduced into the bladder finds a moderate bilateral prostatic enlargement, but no median lobe. The neck of the bladder is drawn in a fold by the lateral outgrowths. Both lobes are incised with the galvano-cautery knife, thus lowering the median fold. The patient has no hemorrhage and no reaction. February 26th, the perineal tube is removed and a full-sized sound introduced. February 29th, the patient is out of bed, most of the urine escaping through the perineal wound. March 15th, the perineal wound has healed, all the urine now escaping from the penis, although the patient complains of having no control of the flow. He urinates every half-hour, there being a moderate dribbling in the intervals. March 20th, the patient's condition has markedly improved, he passing his urine voluntarily, there being but little dribbling, and that immediately after the act of micturition. The patient has gained in flesh, and declares that he feels better than he has felt in years.

Case XIII.—E. H——, seventy-three years old. February 25, 1901, this patient is brought to the hospital in an ambulance, having an attack of complete retention of urine. He has suffered for at least twenty years from frequent urination. A few days previously he had held his urine longer than usual. During the evening he passed the urine very frequently, and there was a constant dribbling between times. Toward morning he had complete retention. A physician was called, who tried medicinal measures, which failed. An attempt to catheterize was unsuccessful. On the same night a consultation was held, and a suprapubic puncture made and a cannula inserted into the bladder. The tube came out the following morning, and was reinserted, the irritation not having been relieved. The tube was left in place for twenty-four hours longer, and was then removed, after which he passed small quantities of urine through the natural passage.

February 26th, operation. A bi-coudé catheter is inserted without difficulty under the anæsthetic and two and one-half pints of retained urine removed. The urethral length is six inches. Perineal cystotomy is performed. A marked bilateral prostatic enlargement is found, and both lobes are incised with a galvano-cautery knife. This incision through the lateral lobes results in a sufficient lowering of the median muco-muscular fold, so that no posterior incision is required. A perineal tube is inserted and removed at the end of one week. No reaction attends the operation. The suprapubic puncture heals without attention. The patient leaves the hospital at the end or four weeks, passing all the urine through the penis, having a residuum of about six ounces. He urinates hourly, and there is a certain amount of involuntary dribbling, which is gradually growing less. He is much improved in general health, has no pain, and is well pleased with his condition.

April 19th. Final examination. He urinates every one and two hours and three or four times at night. There is only an ounce of residuum and a little trickling away of urine after the act. He shows progressive tendency to improvement.

Case XIV.—August 7, 1900. A. A——, aged

seventy-three years, complains of recurring attacks of cystitis. He has had suprapubic cystotomy, but the wound remains fistulous, and the bladder holds only five ounces. The urine dribbles continually, so that he has practically no urinary call, and he urinates, perhaps, a teaspoonful at a time.

September 19th, a perineal cystotomy is performed, and the neck of the bladder is incised with the bistoury. The neck is found to be exceedingly rigid. The fistula is then scraped and sutured. The tube is removed after twenty-four hours. January 3, 1901, the urine is exceedingly purulent and ammoniacal. The patient urinates every three hours with considerable pain. There is a residuum of one ounce. There is a tender lump at the seat of the old fistula; the incontinence has ceased. February 23d, the residuum is one-half ounce. The suprapubic fistula has reopened slowly.

Operation, February 28th, perineal cystotomy. The finger detects a very rigid collar surrounding the urethral orifice of the bladder, which is incised with the galvano-cautery knife 1.25 cm. in length, with 50 amperes current. A perineal tube is inserted. The tube is removed at the end of a week, having caused no local irritation. March 20th, the patient sits up all day for the first time, having been kept in bed solely on account of a spasmodic pain in the muscles of the neck. The bladder has been perfectly peaceful. The perineal wound is healed. The suprapubic fistula has entirely healed, and gives no trouble. He still has incontinence of urine, losing about half the entire amount involuntarily. Urination is every half or three-quarters of an hour. The patient's improvement has no doubt been retarded on account of his general condition, due to the persistence of painful spasm in the muscles of the neck, which has resisted all efforts for relief.

Case XV.—R. H. S——, aged sixty-nine years. December 17, 1900. The patient has had trouble with his bladder for many years. Examination of the urine, November 20th last, revealed 1.25 per cent. of albumin, cells from the pelvis of the kidney, and evidence of pyelitis. The patient's sister died of pulmonary tuberculosis, and he also has two children afflicted with the same malady in its advanced stages. He urinates every twenty minutes, except during the early morning, when the intervals become somewhat extended. The patient has attempted to relieve himself by the use of the catheter, but was compelled to discontinue it on account of severe hemorrhage. The urinary distance is seven inches. The prostate per rectum is felt to be quite small. On account of the constant spasm attendant upon the urinary act, the patient has developed a prolapse of the rectum, which adds greatly to his suffering.

Operation, March 12, 1901. One ounce of residual urine is drawn. Perineal cystotomy is performed. The neck of the bladder is exceedingly tight and will not admit the tip of the finger. A galvano-cautery incisor is introduced and a left lateral incision is made about 1.5 cm. in length. The finger is now introduced and finds the median enlargement quite movable on its attachment to the right side, having been severed by the first incision from the left; a second incision on the right side of this lobe loosens it sufficiently to permit its detachment by the finger through the perineal wound, the portion removed being one and one-half inches in length by one-half inch in thickness. A perineal tube is inserted. No reaction and little hemorrhage follow. The tube is removed at the end of forty-eight hours. The patient sits up at the end of three weeks, passing the urine in part through the perineum and in part by the natural channel. At the end of four weeks practically all the urine comes through the normal channel at intervals of about one hour. There is still some smarting pain at the end of the urinary act, but this is moderate as compared with his suffering previous to the operation, and he is much improved in general health and spirits.

Final examination, April 27, 1901. The patient was prepared to leave for his home in the South, but was prevented on account of a severe attack of facial neuralgia. He now urinates about every two hours by day and less often at night. There are no pain and no dribbling. There is no doubt but that he could retain the urine for a longer interval, but he is of a nervous temperament, and is constantly keeping his mind on the subject.

Case XVI.—J. F. H——, aged seventy-three years. The patient urinates from every twenty minutes to every hour by day and from every ten minutes to every three-quarters of an hour at night. One year ago the urination was every half-hour by day and every hour by night. The prostate per rectum is found symmetrically but not markedly enlarged. The bladder is distended above the pubis, and the patient suffers more or less constantly from overflow. No instrument is introduced into the bladder, as the patient gives evidence of having had uræmic attacks.

Examination of the urine, January 21, 1901. Quantity in twenty-four hours, 2,800 c.c. Reaction, acid. A small quantity of albumin. Specific gravity, 1.009. Amount of urea in twenty-four hours, 11.284 gm. A large amount of pus forms the bulk of the deposit. Some hyaline casts and groups of cells from the pelvis of the kidney are present. The patient is placed upon urotropin gr. xl. in the twenty-four hours.

Second examination of the urine, February 10, 1901. Quantity in twenty-four hours, 3,000 c.c. Reaction, acid. A trace of albumin. Specific gravity, 1.009. Quantity of urea in twenty-four hours, 13.92 gm. A large amount of pus, hyaline casts, and cells from the pelvis of the kidney are present. The patient's general condition has somewhat improved; his tongue has become more moist, the eye is clear, and the skin less dry.

Third examination of urine, March 4, 1901. Quantity in twenty-four hours, 2,280 c.c. Reaction, acid. A trace of albumin. Specific gravity, 1.009. Quantity of urea in twenty-four hours, 10.351 gm. A large amount of pus, hyaline casts, and cells from pelvis of kidney are found. The general condition is about the same, in spite of the damaged condition of the kidneys, and the amount of urea secreted being much below the minimum. After careful consideration, an operation is deemed more expedient than an attempt at establishing catheter life, although the danger of a surgical interference under existing conditions is fully realized. Yet it is decided to be a wiser course to concentrate the danger at one time than to spread it over a longer period by submitting the kidneys to the constant irritating influences of repeated catheterization.

Operation, March 22, 1901. Thirty-one ounces of retained urine is withdrawn, the patient having urinated immediately previous to entering the operating-room. Perineal cystotomy is performed. There is a pronounced median bar and a moderate lateral prostatic outgrowth, notably on the left side. One incision is made with the galvano-cautery knife 2 cm. in length, sufficiently deep to lower the neck of the bladder even with the bas fond, and at a slight angle sufficient to encroach upon the obtruding left lateral enlargement. The operation is conducted with as little expenditure of time as possible, and the patient stands it better than was expected. Twenty-four hours after the operation an analysis of the urine shows an increase of urea to 17 gm. in the twenty-four hours. Forty-eight hours after the operation there is 21 gm. of urea excreted, and seventy-two hours after the operation there is 28 gm. of urea excreted. The tube is

removed at the end of the fourth day. On the tenth day after the operation the patient has three chills, varying in duration from fifteen minutes to half an hour each, and his condition causes considerable concern. He rallies, however, in the next twenty-four or forty-eight hours, and on the seventeenth day after the operation the patient sits up out of bed. The urine all passes by way of the perineal wound by continuous dribbling, and there is still from six to ten ounces of residuum; but this, while purulent, is free from odor of decomposition.

April 15th, examination of urine reveals only one per cent. of urea, and the patient's general condition, instead of continuing to improve, shows evidence of failing. From this time on there is increasing evidence of kidney insufficiency, and the patient is no longer able to sit up out of bed. This failing condition progressively and gradually grows worse, and death occurs April 25, 1901, about five weeks after the operation.

In connection with this case it might be remarked that an operation was of questionable propriety. It is extremely doubtful, however, whether the kidneys in their damaged condition would have sustained an attempt at frequent catheterization, and the fact that the patient lived five weeks after the operation is evidence that he did not die from its immediate effects, but from the gradually increasing pyelo-nephritis.

Is There Such a Constituent of Urine as "Ureine"?—W. S. Haines and C. S. Woods, of the Rush Medical College Department of Chemistry, take exception to the alleged discovery of a new constituent of the urine, as claimed by Moor. Their objections are maintained in the following propositions: 1. It is in the highest degree improbable that, if such a substance existed, it would not long have been discovered in view of the vast amount of work which has been done on the chemistry of this fluid. 2. The foundation on which the discovery is based has no existence in fact, as several well-known components of urine will produce the reaction which Moor claims to be characteristic of ureine. 3. The latter is simply a strong aqueous solution of well-known urinary solids and of chemicals used in operating on the urine. 4. Considerations in connection with specific gravity of the urine afford conclusive proof of the non-existence of ureine. 5. If ureine is the poisonous element in urine, then the toxicity of the latter would disappear if the former were destroyed, but this is not the case, as experiment will easily show.—*Medicine*, April, 1901.

The Value of the Leucocyte Count in the Diagnosis and Prognosis of Appendicitis.—E. H. Season says that with most abdominal troubles the leucocyte count will help us more than any other single means at our disposal. The presence of a marked leucocytosis excludes simple colic and intestinal obstruction, excepting in those cases associated with ulceration or gangrene. A leucocytosis, if marked, would point to a general peritonitis, rather than to appendicitis, in cases in which these two affections were to be differentiated, though a leucocytosis may be absent in either. In conclusion, it is important to remember that the normal number of white blood corpuscles varies between 5,000 and 10,000 per cmm., and that a moderate leucocytosis exists in the new-born, during digestion, during pregnancy, post partum, after violent exercise, and after cold baths, while in tuberculosis, typhoid fever, and malaria the leucocytes are normal, or below normal, except in those cases associated with other complications. Finally during starvation or fasting the blood shows a leucopænia.—*Cleveland Journal of Medicine*, April, 1901.

The Cure and Prevention of Scarlet Fever by the Use of Diphtheria Antitoxin.—C. H. Dalton says that two years ago he accidentally discovered that diphtheria antitoxin was an excellent remedy in the treatment of scarlet fever, and later investigation proved that it was equally as efficacious in the prevention of the disease. He has now tried it in a large number of cases, so many, in fact, that he must conclude that it is a sovereign remedy in the treatment and prevention of the disease. He has used antitoxin in over thirty cases since, and has immunized the other children in the families. None of them had the disease. None of the patients died, and a number of them had the disease in a severe form. A fact which impressed him particularly was the mild form assumed after the use of antitoxin in a number of cases which were running a severe course. It is in the bounds of possibility that, if he had not used the antitoxin, the patients would have gotten along just as well and none of the other children would have taken the disease, but, in view of the large number of children involved and the contagious nature of the disease, it seems that this is highly improbable.—*St. Louis Medical Review*, April 6, 1901.

Alcoholism in Childhood.—M. Kassowitz has seen both functional disorders, such as delirium tremens, alcoholic mania, and epilepsy, and actual organic lesions follow the protracted use of alcohol in children, and believes that they are often produced by even the milder forms of stimulating beverages, such as beer and light wines, given in amounts universally regarded as harmless. It, therefore, seems justifiable to conclude that there is an especial susceptibility of the immature organism as a whole, and especially of its nervous system, to the effects of alcohol, and the prevalent belief that small amounts may in some conditions of weakness and disease be advantageously given to children as a tonic and roborant, is unfounded. Physiological investigation has shown that the older view that alcohol is a food and capable of preventing tissue destruction is groundless, for nitrogen elimination is increased and not diminished by it, and it is a close corollary to this observation that stunting in growth and development follows its protracted use in children. Furthermore, it is deficient in the very properties for which it is most often given, for it is a hindrance and not an aid to digestion, is dangerous as an antipyretic, its stimulating effect is fleeting and followed by muscular and nervous depression, and its use as an internal antiseptic in the infectious diseases is in the light of recent animal experiments wholly irrational, so that its administration to children in sickness or health is absolutely to be deprecated.—*Wiener klinische Rundschau*, April 7, 1901.

MEDICAL RECORD:

SOME CLINICAL ASPECTS OF CHRONIC NEPHRITIS.

WHILE the medical profession should be ever ready to honor those of its members who have distinguished themselves and advanced their art by important discoveries, the wisdom of employing eponymic designations in this connection is questionable, because they are necessarily undistinctive, at times confusing, and thus obstructive of progress. Thus the same name may be, and actually has been, applied to more than one condition; then, with the growth of knowledge it may be found that the limitations of the original name have not been perfectly defined; finally, there are few minds so capacious as to be able to store up all of the proper names that have at different times been proposed. Some of these difficulties are illustrated in the employment of the term "Bright's disease." Although the association of disease of the kidneys, albuminuria, and dropsy had been previously noted, to Bright belongs the credit of having first pointed out the dependence of the latter two upon the first; but several morbid conditions of the kidney were comprehended in the description of Bright, so that after all it seems better, for the sake of clearness and accuracy, to employ the generic designation nephritis with its several qualifications—acute, chronic, parenchymatous, interstitial, lardaceous, cystic, etc.

A view somewhat opposed to this is taken by Dr. Alfred G. Barrs (*British Medical Journal*, March 30, 1901, p. 753) in an address on "Some Clinical Aspects of Chronic Bright's Disease" recently delivered. He contends that the pathological distinctions made between the different forms of so-called chronic Bright's disease have little clinical value, and that there is no practical utility from a therapeutic or a prognostic standpoint in distinguishing between a large white and a small red kidney, even if it were possible to do so with certainty.

The important fact to determine, he thinks, is whether the condition be acute or chronic, as the chances of recovery are then good or bad respectively. Acute nephritis, Barrs believes, terminates either in recovery or in death, while chronic nephritis is so from the outset, and he suggests the possibility of a bacterial origin for the latter.

The opinion is expressed that the diagnosis of chronic Bright's disease cannot safely be made in the absence of albuminuria, although it is not denied that renal changes—Bright's disease in a pathological sense—may exist and the urine be free from albumin. No importance whatever is attached to the quantitative estimation for albumin, and the estimation of urea is not thought to be of any great value. The cardio-vascular changes, it is believed, are not so uniformly inevitable or so common as is generally held. The statement is made that arteriosclerosis, altogether independent of renal disease, is a far more common cause of cardiac hypertrophy than Bright's disease, and vascular disease of this nature is probably a cause as well as a result of rena ldisease. As a natural corollary chronic renal disease is not looked upon as having nearly such a common association with cerebral hemorrhage as has been supposed. Toxæmia, the inevitable result of progressive destructive disease of such a vital excretory organ as the kidney, is considered the direct and only cause of death in the vast majority of cases.

In the matter of diet Dr. Barrs makes it his rule that if the bowels are acting freely the patient may live on such ordinary mixed food, including meat, as he has appetite for and can digest. Water and other fluid sustenance should be taken freely; alcohol is to be avoided unless demanded by cardiac failure; climatic treatment may be a valuable adjunct. Of drugs nothing beyond the systematic use of purgatives, to keep the bowels acting freely, will be needed except for the treatment of special symptoms as they arise. Dr. Barrs has no great faith in the so-called vicarious action of organs, and he believes that the proper way out of the body for urea is the kidneys, and neither the intestines nor the skin can be made to take its place efficiently. Diuretics such as digitalis are frequently of the greatest use, but they almost as frequently fail. Diaphoretic drugs, such as pilocarpine, are sometimes unpleasant and even dangerous in their effects, the hot bath and the hot-air bath being depended upon to do all that can be done. Vaso-dilators have little if any diuretic action, but may relieve dyspnœa, headache, and vomiting. Bleeding, purgation, and sweating are employed for the relief of nervous and respiratory disturbances. Morphine and opium should not be used as a rule, but not infrequently the former alone will relieve distressing and painful respiratory and mental disturbances.

The views thus briefly summarized are, as will have been seen, not in accord with current opinion; but without agreeing with them we must at least give them respectful consideration, emanating as they do from a most responsible source. A discussion in detail would carry us too far and besides seems unnecessary. In all scientific controversy, however, the motto "Audi alteram partem" is a good one to adopt.

Medical Student Killed.—W. L. Royce, a member of the senior class of the Kentucky School of Medicine and an interne at the College Hospital, Louisville, was stabbed to death a few days ago by a negro who was employed as a helper in the dissecting-room.

RACE DISTRIBUTION OF CANCER IN BUFFALO.

At a recent meeting of the Buffalo Academy of Medicine, an account of which is published in the Buffalo *Medical Journal* for May, Dr. Lyon, of that city, read a paper of much moment upon the distribution of cancer in Buffalo for the past twenty years.

The death rate from cancer in Buffalo has shown a steady increase, rising from 32 to 53 per 100,000 population from 1880 to 1899. The age distribution agreed with other well-known statistics.

The significant and suggestive portion of the paper was that which dealt with the race distribution. The statement was made that Germans and Poles constituted 42 per cent. of the cancer mortality of the city, though making only 20 per cent. of the population. Those of native American birth constituted only 29 per cent. of the cancer mortality, as against 65 per cent. of the total population of the city.

The distribution of cancer by organs involved, in the different classes of population, was most important. Cancer of the stomach occurred in 47 per cent. of all males and in 25 per cent. of all females dying of cancer, or 34 per cent. of both sexes. For the Germans and Poles the corresponding figures were 52 per cent., 35 per cent., and 43 per cent., and for those born in the United States 37 per cent., 13 per cent., and 21 per cent.

From these statistics it will be gathered that the proportion of cancer of the stomach and cancer of all organs is more than twice as great in the Germans and Poles as in the native-born of Buffalo.

As Dr. Lyon remarks, this fact seems of great importance in pointing to diet as a probable factor in determining the frequency of location of cancer in the stomach, and he goes on to say, accepting this explanation, Then how can the diet affect this result?

The choice lies between two theories: (1) The diet may be supposed to infect the stomach with a cancer-producing organism, which organism occurs in certain articles of diet, more frequently used by the Germans. Or (2) it may be supposed that the German abuses his stomach by his food and drink and thus increases its liability to cancer. This theory is in accord with the trauma theory and that of Cohnheim. Dr. Lyon is of opinion that the evidence for the abuse of the German stomach is not strong enough to support this theory, and that the doubled frequency of attack of the German stomach, as compared with the American stomach, is best explained by the theory of direct infection through diet.

Behla's observations support the parasitic theory and cast suspicion on uncooked vegetables as the carriers of infection. It is notorious that the Germans are great eaters of raw vegetables, salads, and the like. Dr. Lyon concluded by declaring that; whatever the theory of explanation, the fact remains that the German stomach is remarkably liable to invasion by cancer.

That the Germans are peculiarly susceptible to cancer of the stomach is, so far as we are aware, a coincidence which has not been made the subject of public notice previously, and, before accepting the statement as proven, it will be well to study statistics bearing upon the question in Germany itself, as well as in other American cities besides Buffalo, which have a large German population, for it may be presumed that the food of the Teuton is much the same in all civilized countries.

If after this has been done it is clearly demonstrated that the German does suffer largely from cancer of the stomach, a sound *a priori* argument will have been provided that his diet may be a factor in its causation. At any rate, the point is worthy of investigation.

In the discussion that followed the reading of Dr. Lyon's paper, the question as to whether the German or native American most abused his stomach was gravely debated, and the consensus of opinion seems to have been that the German is the greater sinner in this respect. With this conclusion there will be, except among the Germans themselves, a unanimous agreement, for, although the American is careless with regard to his food and eats too quickly, he is not, like the German, a gross feeder.

GENERALIZED GONORRHŒAL INFECTION.

It is recognized as a fundamental principle in pathology that infectious processes are in general primarily local. From the site of local infection the invading bacteria may gain entrance into the blood-vessels or the lymphatics, or they may continue their attack by continuity or contiguity of structure. At each place of lodgment they give rise to lesions comparable in some degree to the original, and the resulting manifestations are local in character. By reason, however, of their vital activity and the reactions that occur between them and the fluids and cells of the body, certain toxic products are generated to which the constitutional symptoms are due. We thus have to do with two principal conditions: (*a*) Infection, which may be local or general; and (*b*) intoxication. General infection may be designated also bacteræmia; if dependent upon pyogenic micro-organisms, with the development of metastatic abscesses, the condition is one of pyæmia. Now, these terms are sufficiently descriptive and comprehensive, and should render unnecessary the further use of others, such as septicæmia and sapræmia, that were devised at a time when knowledge of infectious processes was less complete and less exact than at present.

It is self-evident that general infection can occur only with aerobic bacteria, and it seems a fair inference that such infection may be due at times to any of these bacteria. This has been demonstrated with regard to a number of micro-organisms, such as the typhoid bacillus, the plague bacillus, the diphtheria bacillus, the pneumococcus, the anthrax bacillus, the influenza bacillus, the tubercle bacillus, the streptococcus, and the staphylococcus; but even with the most of these the local infection is the more conspicuous, while the constitutional symptoms are due to the general intoxication.

Gonorrhœa was for a long time looked upon as merely a local infection, although its gravity, by rea-

son of extension by continuity, has been duly appreciated. The accumulating experience of the last decade, however, has all too abundantly shown that the gonococcus also may be the cause of severe and even fatal general infection. Synovitis, endocarditis, and myelitis are perhaps among the best known of the complications of this character. In a discussion of this subject Arthur H. Ward (*British Medical Journal*, March 30, 1901, p. 755) undertakes to show that the constitutional symptoms associated with gonorrhœal infection are due to absorption into the system of an irritating toxin generated by the gonococcus and causing systemic degenerations of varying degrees of severity. He holds that gonorrhœa is a general toxæmic affection, the microbes generating the toxin being usually localized on or around a mucous tract. Extension of the infection is thought to be favored by the paralyzing action of the absorbed toxin on the leucocytes, thus preventing encapsulation of the microbes. As a result the gonococci reach the circulation and are carried to the heart, the endocardium, the pericardium, the pleura, the joints, and elsewhere.

Such invasion of the organism, it is believed, is contributed to by unduly energetic measures aimed at the local infection, which, by depressing the local powers of resistance and abrading or lacerating the mucous surface, may directly open the way to infection. These dangers are to be averted by the avoidance of all measures capable of injuring or abrading the mucous lining of the urethra, such as instrumental treatment during the acute stage of the disease, the employment of injections under high pressure, or of abortive antiseptics. When constitutional infection has taken place the internal administration of germicides, such as quinine, mercury, arsenic, and salicylates, is recommended. Further, potassium iodide may be administered with large amounts of water; baths, massage, and exercise employed, and change of air recommended.

ANTI-TYPHOID INOCULATION.

As we pointed out a short time ago (April 27th, p. 659), the results of observations as to the utility of inoculation in reducing the morbidity and mortality of typhoid fever are not so entirely unequivocal and unanimous as to permit of a final decision in this matter. We were then able to quote statistics indicating a favorable influence attributable to inoculation. In the judicial spirit we have to quote to-day figures—though on a somewhat smaller scale—of an opposite character. In making a report on 295 cases of typhoid fever observed during the spring of 1900 at the General Hospital, Ladysmith, South Africa, Dr. David Melville (*British Medical Journal*, April 20, 1901, p. 952) states that among this number inoculation was practised in 30, in 6.67 per cent. of which death took place, as compared with 1.89 per cent. in uninoculated cases. Complications, further, occurred in 40 per cent. of the inoculated, as against 20.75 per cent. of the uninoculated cases. This is apparently a damaging exhibit for the cause of inoculation, but it proves almost too much, apart from the fact that the number of cases is entirely inadequate to eliminate the influence of accident. There is certainly no reason to believe that if inoculation does not protect from, it predisposes to typhoid infection. It may be found, besides, that the results of the experience here quoted may be in some way related to the mode of procedure adopted. Immunity is practically always only relative and never absolute, and its duration, as its degree, is susceptible of considerable variation. These facts must always be weighed in the final analysis.

News of the Week.

The Late Dr. F. J. Brockway.—"The members of the West End Medical Society desire to express their sorrow at the death of their fellow-member and former president, Dr. Fred. Brockway. This is to be taken not merely as a formal record of the feeling of the society as a body, but as the expression of a genuine sense of loss on the part of each individual member. While the death of our colleague makes us regret the loss to the profession of his solid abilities as a practitioner and teacher, on the other hand his sterling qualities as a man and friend, his absolute reliability, his sound common sense, and, last but not least, his fund of quiet humor, all constituted a claim to the personal regard of each member, such as to call forth that regard in its highest form. The society wishes Dr. Brockway's family to know of the great esteem it had for him, and it hereby expresses to them its deepest and most heartfelt sympathy.

"*Resolved*, That the above minute be entered in full on the records of the society, and that a copy be sent to the family of our deceased colleague. B. B. Gallaudet, M.D., J. E. Newcomb, M.D., Committee."

University of Pennsylvania.—Dr. Thomas R. Neilson has been elected clinical-assistant professor of genito-urinary diseases in the medical department.

Willard Parker and Reception Hospitals.—Dr. Louis Fischer has been appointed visiting physician to the Willard Parker and reception hospitals of the health department of this city.

Mount Sinai Hospital.—The ceremony of laying the corner stone of the new Mount Sinai Hospital, at Fifth Avenue and One Hundredth Street, will be conducted by Mr. Isaac Wallach, president of the hospital, on May 22d. The speakers will be Governor Odell, President Seth Low of Columbia University, Mr. Randolph Guggenheimer, Mr. Edward Lauterbach, and Dr. A. Jacobi.

Dr. Frederick Peterson, of this city, has been appointed by Governor Odell the medical member of the State Lunacy Commission to succeed Dr. Wise, who was removed by Governor Roosevelt. Dr. Peterson's appointment carries with it the office of president of the commission. The term is six years and the salary $5,000, with $1,200 allowed annually for expenses. Dr. Peterson is to devote about a third of his time to

his new duties, and is not obliged, therefore, to relinquish his practice in the city. He sets a good example in being willing to make a financial sacrifice, which we know he does, to fulfil the duties of an office in which much good can be accomplished in promoting the welfare of the insane and the course of medical science.

The Grave of Hippocrates is said to have been discovered recently in the course of some excavations at Larissa, in Thessaly.

The Plague at Cape Town.—Up to Saturday, May 11th, it is stated that there have been six hundred and ten cases of plague and two hundred and seventy-five deaths from the same at Cape Town.

A Trolley Ambulance.—The officials of the Brooklyn Rapid Transit Company have in mind the establishment of a receiving hospital for the extension of first aid to persons injured on the lines of the company. There will also be a trolley ambulance service provided.

A New Use for Quarantine.—According to a veracious correspondent of the London *Daily Chronicle*, the Sultan learned that a band of anarchists was on the way to Constantinople with the intention of assassinating him. In order to keep them out, he got up a plague scare and imposed a very strict quarantine.

The Louisiana Lepers' Home.—The Gustine plantation has been bought for a lepers' home, but may not be used for that purpose. Strong opposition against the establishment of the home in that locality has been aroused among the people of the surrounding parishes of Jefferson and St. Charles, and a mass meeting in protest was recently held. The school boards and boards of health of Jefferson and St. Charles parishes and the town council and board of health of the city of Kenner have also joined in the petition against the location of the lepers' home.

Prize Essays on Subjects Connected with Tropical Diseases.—It is announced in the *Journal of Tropical Medicine* that: 1. A prize of the value of £10, entitled the Sivewright Prize, presented by Sir James Sivewright, K.C.M.G., will be given for the best article on "The Duration of the Latency of Malaria after Primary Infection, as Proved by Tertian or Quartian Periodicity or Demonstration of the Parasite in the Blood." 2. A prize of the value of £10, entitled the Belilios Prize, presented by the Hon. E. R. Belilios, C.M.G., will be given for the best article on "The Spread of Plague from Rat to Rat, and from Rat to Man by the Rat Flea," to be substantiated by experimental proof. The papers must be sent to the editors of *The Journal of Tropical Medicine*, 83–89 Great Titchfield Street, London, W., by December 1, 1901. All papers sent in become the property of the journal, and will be published as the editors decide. The competition is open to qualified medical practitioners of every nationality. The papers may be written in English, French, German, Italian, or Spanish. The names of the prize winners will be announced in January, 1902, in the public press and in the medical journals. The judges are: Surgeon-General Roe Hooper, C.S.I., president of the Medical Board, India Office; Col. Kenneth MacLeod, LL.D., professor of clinical and military medicine, Netley; Patrick Manson, C.M.G., F.R.S., LL.D., medical adviser Colonial Office and crown agents of colonies.

Dr. Harriet E. Blach, of Amityville, has been appointed physician in the Long Island State Hospital at a salary of $1,000.

The American Laryngological, Rhinological, and Otological Society.—The seventh annual meeting of this society will be held in the New York Academy of Medicine on May 23, 24, and 25, 1901, under the presidency of Dr. Robert C. Myles, of this city. The secretary is Dr. Wendell C. Phillips, 350 Madison Avenue, New York City.

Smallpox continues to prevail in this city to a degree which does not speak favorably for the efficiency of the board of health under its present management. The members of the police force were vaccinated last week on the order of Commissioner Murphy, a policeman having been taken with smallpox a few days ago.

A Dangerous Post is that of physician to the ruler of Turkey, if we may believe a tale recently told by the London *Daily Express*. According to this paper, an aurist, who was lately treating the Sultan for an affection of the ear, accidentally touched the drum membrane, causing his patient intense pain. His Majesty, believing that an attempt was being made on his life, drew a revolver and shot the physician dead. A chamberlain hearing the shot entered, and the Sultan fired at him, wounding him.

Meeting of the American Medical Editors' Association.—The annual meeting of the American Medical Editors' Association will convene in the library rooms of the Ramsey County Medical Society, Lowry Arcade building, St. Paul, at 2:30 P.M., Monday, June 3d. The annual dinner will take place at 9 P.M. of the same day. The president of the association is Dr. Alexander J. Stone, of St. Paul, and the secretary Dr. O. F. Bell, Century Building, St. Louis, Mo.

An International Congress of the Medical Press will meet at Brussels on September 20, 1901. Any representative of a legitimate medical journal is entitled to membership in the congress, but there are also to be official delegates, four each from Germany and Austria, three each from France, Italy, Great Britain, and the United States, two each from Spain and Russia, and one each from the other nations of the world. At this meeting it is proposed to draw up a plan and rules for an International Association of the Medical Press. The secretary of the congress—the second of its kind, the first having been held in Paris last summer—is Dr. Pechere, Rue de la Loi. 140, Brussels, and to him all communications relating to the congress should be addressed.

Dr. Henry L. Woodward, Jr., of Glendale, Ohio, was the recipient of the "faculty prize" at the eighty-second commencement of the Medical College of Ohio,

now the medical department of the University of Cincinnati, on May 7th. This prize, a large gold medal, is awarded for "general excellence." The faculty prize man also receives from "a friend of the college" one year's subscription to a weekly medical journal. There were sixty graduates.

Willis Eye Hospital.—Dr. S. Lewis Ziegler has been elected surgeon in succession to Dr. George C. Harlan, resigned.

Pathological Society of Philadelphia.—At a stated meeting held May 9th, Dr. William S. Wadsworth read a report of "A Case of Ball-Clot in the Auricle; Death by Occlusion." The patient had been a muscular iron worker in apparently good health, but who had been on a debauch. Death resulted suddenly, and post-mortem examination disclosed an enlarged and hypertrophied heart and narrowing and obstruction at the mitral orifice, with vegetations upon the valve leaflets, and a globular thrombus as large as an ordinary lemon in the left auricle, covered by a sort of hood, which may have been attached to the auricular wall at one point. Dr. F. S. Pearce exhibited "Two Specimens of Hemorrhagic Pachymeningitis," the symptoms in one case being suggestive of ingravescent intracerebral hemorrhage, with spastic symptoms. The condition was unilateral in each instance. Dr. Pearce exhibited also a specimen of "Tumor of the Spinal Cord" from a demented woman, who presented symptoms of spastic paraplegia. The growth originated from the dura and pressed upon the anterior surface of the dorsal cord. It was thought to be an endothelioma. Dr. W. Wayne Babcock exhibited some new apparatus: (*a*) a device for measuring fixed quantities of culture media or the like in many equal parts; (*b*) for washing sections of tissue contained in their original bottles; (*c*) for staining sections on slides to the number of one or two at a time, with the expenditure of little staining material, and to facilitate the application of heat; (*d*) for mounting celloidin-embedded specimens upon paraffin. Dr. Joseph Walsh read a paper entitled "Diphtheria Bacilli in Noma," in which he related eight cases of this disease, some following diphtheria, some measles, attended with the presence of diphtheria bacilli. In several of the cases recovery took place. The diphtheria bacilli were thought possibly to favor infection with and the action of certain unidentified putrefactive bacteria. Drs. W. E. Hughes and Joseph McFarland read a report of a case of "Rupture of the Aorta." An L-shaped laceration of the intima and media of a moderately atheromatous aorta had taken place a short distance above the posterior sinus of Valsalva, with extravasation of blood between intima and adventitia and leakage into the pericardial cavity. Dr. C. W. Burr exhibited a specimen of "A Brain with Thrombosis," presenting wasting in the left motor area. During life there had been right hemiplegia, with total loss of common and special sensibility on the same side for several years, replaced by the appearance of the sensory changes on the opposite side, which disappeared before death, but without other hysterical stigmata. Dr. Burr was therefore unwilling to consider the derangement of sensibility as hysterical, although unable to offer any other macroscopic explanation. Dr. Burr exhibited also a specimen of "Hemorrhage into the Pons Varolii."

German Evasion of Military Service.—A number of physicians and others were convicted recently at Elberfeld, Germany, of administering drugs to young men with the purpose of fraudulently enabling them to evade military service. The heaviest punishment imposed was seven years' imprisonment and the deprivation of civil rights for five years more.

Stock-Market Speculation and the Death Rate.—In a recently issued report of the Chicago board of health, an increase in the death rate among persons over sixty years of age is attributed to the excitement attending stock speculation. Of 566 deaths during the week, 124 were of persons sixty years old or older. This is an increase of 26 per cent. over the previous week and of 24 per cent. over the corresponding week of 1900.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy, for the week ending May 11, 1901. Assistant Surgeon J. S. Taylor detached from the *Manila* and ordered to the naval hospital, Yokohama, Japan. Assistant Surgeon F. L. Benton detached from the naval hospital, Yokohama, and ordered to duty on the Asiatic station. Medical Director E. Z. Derr detached from the Naval Academy and ordered home to wait orders. Surgeon F. W. F. Wieber detached from the San Juan naval station and ordered to the Naval Academy May 6th. Surgeon C. H. T. Lowndes detached from the *Lancaster* May 11th and ordered to the San Juan naval station *via* the *Mayflower*. Passed Assistant Surgeon E. S. Bogert ordered to the *Lancaster* May 11th. Surgeon L. W. Curtis detached from the *Vermont* May 11th, and ordered home to be in readiness for sea duty. Surgeon G. Pickrell ordered to the *Vermont* May 11th. Surgeon C. F. Stokes detached from the Asiatic station and ordered home *via* mail steamer.

College of Physicians of Philadelphia.—At a stated meeting held May 1st, a discussion was held on "The Relation of Diseases of the Heart to Surgical Operations, Especially in the Use of General Anæsthetics." Dr. W. J. Mayo, of Rochester, Minn., by invitation, read a paper entitled "Pre-Existing Heart-Disease in Reference to Surgical Operation." He emphasized the fact that the greatest importance is to be attached to the condition of the myocardium and to the state of compensation. Dr. H. A. Hare made a communication entitled "The Safest Anæsthetic to use in Organic Diseases of the Heart and Vessels." He pointed out the disadvantages resulting from inability to know how much of the anæsthetic the patient actually inhales, and how much is lost. He expressed the opinion that a source of danger resides not alone in the failure of the heart, but also in that of the vascular system, and he contended that even more is to be feared in the presence of disease of the

vessels than in that of disease of the heart alone. Perhaps less importance is to be attached to the anæsthetic itself than to the care in and manner of administration. The question of personal idiosyncrasy must also be taken into consideration. Ether he held to be in general the safest anæsthetic except in the presence of disease of the respiratory passages, some of the complications resulting from which may at times be averted by a preliminary dose of atropine. Dr. J. M. T. Finney, of Baltimore, Md., by invitation read a paper entitled "The Cardiac Complications which may Arise during an Operation," and Dr. Alfred Stengel one entitled "The Cardiac Complication which may Arise after Operation." Dr. A. J. Ochsner, of Chicago, also made some remarks in the discussion.

Obituary Notes.—Dr. Charles Rice, one of the leading apothecaries of the country, and for twenty years chemist of the New York charities department, died in Bellevue Hospital on May 13th. Dr. Rice was born in Munich, Bavaria, in 1841, and was educated in Vienna, Munich, and Passau, acquiring a thorough mastery over several Oriental languages, the classics, and modern tongues. He came to America in 1862, and entered the navy as surgeon's steward during the Civil War, serving until 1865. He then entered the service of the department of charities and correction. He became a member of the New York College of Pharmacy in 1867, and served as one of its trustees. He became chairman of the pharmacopœia committee of the American Pharmaceutical Association, and also chairman of the committee on revision of the United States Pharmacopœia Commission. He received the honorary degree of Doctor of Philosophy from the University of New York, an honorary fellowship from the New York Academy of Medicine, and was recently made an honorary member of the Philadelphia College of Pharmacy.

Dr. George C. Jarvis, of Hartford, Conn., died at his home in that city on May 7th of pneumonia, at the age of sixty-seven years. He was graduated in arts from Trinity College in 1855, and in medicine from the University of the City of New York in 1860. During the Civil War he served as surgeon to the Seventh Connecticut Regiment.

Dr. James Hayes, a retired physician, died at his home in Plainfield, N. J., on May 12th. He was born in Newark, his father being Dr. Samuel Hayes of that city, and was graduated in arts from Princeton in 1841. Later he studied medicine and received his degree from the College of Physicians and Surgeons in this city in 1854. He practised medicine for several years in Brooklyn and then removed to Plainfield.

Dr. E. Stanley Perkins died on May 6th, at Philadelphia, at the age of fifty-nine years. He was graduated from the medical department of the University of Pennsylvania in 1859, and at the outbreak of the Civil War he became a surgeon in the United States navy. He was for several years a demonstrator of surgery in the Medico-Chirurgical College, and since 1893 one of the examining physicians for the local pension board.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

WAR HONORS—VOLVULUS—URETERAL CALCULUS—ANTENATAL THERAPY—TOXIC EFFECT OF ANILINE OIL—PLAGUE—RICHMOND HOSPITAL—METCHNIKOFF AT MANCHESTER—OBITUARY, DRS. MOORE, TANNER, STONE.

London, April 26, 1901.

A long list of honors and promotions for services during the war has been issued and comprises a considerable number of medical names. These rewards are all for services in South Africa up to November 29, 1900. Subsequent services will be dealt with in a later gazette. The civil surgeons who went out receive recognition in the Order of the Bath, while those of St. Michael and St. George and the Distinguished Service Order are utilized for the Royal Army Medical Corps, as is also promotion in the corps. There is a curious omission in the list—the name of the director-general of the department. I should have thought the time had arrived for recognizing the man on whom the onus of the medical provision fell and who has been commended in all directions. Perhaps his honor is delayed to make it the higher.

Dr. J. H. Bryant brought a case of volvulus of the ileum accompanied by severe hemorrhage before the Clinical Society. The nature of the case was not diagnosed during life, as hemorrhage is so rare in any form of intestinal obstruction except intussusception. The patient was a man aged twenty-one years, admitted with severe pain. Next day he became collapsed and passed about a pint of bright red blood with a mass of undigested food. The hemorrhage recurred during the night, and he died the day after. The volvulus extended over 100 c.c. of the bowel, the wall of which was thickened. The torsion was from left to right, the color deep red, and the peritoneal coat covered with recent lymph. Dr. Bryant had been able to find only one case of volvulus of the small intestine in which much blood was recorded to have been passed per anum.

Mr. Zum Busch said he had seen a case of hemorrhage accompanying obstruction from hernia and one from strangulation by a band of adhesions. Mr. Symonds described a similar case of volvulus operated on in 1882, but the patient died. Dr. Sidney Coupland remarked that the reason of hemorrhage in intussusception was that obstruction is incomplete. He thought possibly in Dr. Bryant's case intussusception preceded the volvulus.

Dr. Dalton said they must distinguish between strangulation of the bowel and of the vessels, and Dr. Bryant, in his reply, mentioned that in his case the blood-vessels were completely obstructed, but the bowel was only incompletely so.

Mr. F. J. Steward reported at the same meeting a case of ureteral calculus simulating vesical calculus. The bladder was sounded without a stone being found, and two radiographs which were taken revealed nothing. The bladder was inflated with air and opened above the pubes. Then a calculus could be felt impacted in the right ureter, two inches from its orifice, but it could not be moved down, so the wound was closed. By a second operation the abdomen was opened and the stone pushed up to a point just above the common iliac artery and the ureter incised. The stone was thus reached and removed. No leakage took place, and the patient was soon convalescent.

In some remarks that followed it was suggested that the stone might possibly have been felt per rectum; a case was mentioned in which a radiograph seemed to show a stone in the bladder, but it was really in the lower end of the ureter; it was suggested that leakage might be dangerous, but another speaker questioned whether normal urine was in itself dangerous to the peritoneum. Mr. Steward admitted as much, but said in this case there had been pus in the urine for some time before the operation.

Dr. Brook, of Lincoln, brought before the Clinical Society the case of a hæmophilic lady to whom he had given calcium chloride and other drugs during her pregnancy with the hope of increasing the coagulability of the blood. Delivery took place at term without complication, and the child had exhibited no tendency so far to hemorrhage, not even at vaccination, but his brothers had shown symptoms at this age, and of course he might yet suffer later on.

Dr. Coupland thought that the mother might have benefited, but this could scarcely be said of the fœtus. It would require many observations to prove the treatment of value.

Dr. St. Clair Thompson then read notes of a case of poisoning by aniline oil, used as a vehicle for cocaine in the auditory meatus. Reference was made to other cases showing that the oil might be absorbed by the skin. The dark-blue color was characteristic, but subsided next day. The cardiac dilatation also passed away and no murmur was produced.

On Saturday the new Richmond Surgical Hospital, in Dublin, was opened by the Lord Lieutenant of Ireland. The new building, I am assured, is equipped with every modern improvement, and must therefore be a great advance on the old Richmond, which had done long and noble service under a succession of most distinguished doctors.

The daily papers have been circulating a report of a case of suspected plague in London. A lad in St. Bartholomew's exhibited some suspicious symptoms and was seen by the medical officer of the County Council, who has been employed to watch for such an occurrence. The patient was removed to the hospital for infectious diseases; contacts were disinfected, and all precautions taken. Dr. Klein undertook a bacteriological investigation, but was unable to certify the case as plague. The patient is getting well, but he seems to have had some form of minor illness which might well suggest plague and would pass as such in an epidemic. The question arises, What was its nature?

The deaths in London fell last week to one hundred and sixty below the decennial average. Only eleven were due to diphtheria, the lowest number for twelve years. Influenza is still on the increase, thirty-one deaths being registered as due to that disease. Scarlet fever has fallen to one.

Manchester had the pleasure of entertaining Professor Metchnikoff on Monday, when he received the Wilde medal and delivered the Wilde lecture. He spoke in French, which was a disappointment to some of those present. His subject, microbes, is sufficiently difficult when treated in one's native tongue. By way of reconciling the existence of the toxic microbes with evolution, according to which they should have long since been eliminated, he remarked that the organs which chiefly supported them were useless. The capillary follicles only represented the hair of our ancestors. The appendix vermiformis was a vestige, and so on. He even went so far as to speak of the stomach as a mere reservoir, observing that four persons were living from whom it had been removed. Surgeons might therefore assist the slow process of evolution. We could do very well, he thought, with a third of the present length of intestine. I doubt not that surgeons in this instance also will be ready to do their share, but if evolution depends on such arguments if must be in a bad way. I feel almost as disrespectful to the doctrine as the learned lecturer is to the alimentary canal.

Dr. William Moor, of Dublin, died on the 17th inst., aged seventy-five years. He was long physician in ordinary to Queen Victoria, and had been appointed to the same position to the king. He served at one time as crown representative on the Medical Council. At Trinity College he was king's professor of medicine and examiner in clinical medicine. He will be greatly missed in Dublin, where for the best part of half a century he was a leader of the highest character for uprightness. You may remember his treatise on "Typhus and Typhoid," or his lectures on "Aneurism." Here he was regarded as a sound physician and worthy representative of the Irish school of medicine, whose friendship it was an honor to enjoy.

Dr. Tanner, M.P., died on the 21st inst. You will remember that his career has been rather political than medical, and a stormy one at that. But he was for some time on the staff of more than one Cork hospital, and a demonstrator of anatomy in Queen's College.

Mr. George Stone, of Liverpool, held a very high rank among otologists. He was for many years ophthalmic and aural surgeon to the infirmary, but for some years past had confined his practice to aural cases. He was a scholar and linguist, and much respected. His translation of Politzer's "Anatomy of the Ear" is well known. He succumbed to an attack of pneumonia on the 21st inst., aged fifty-two years.

Dr. Rolleston, of St. George's Hospital, is going to South Africa to succeed Dr. Washburn at the Imperial Yeomanry Hospital.

Mr. Stonham has returned and is already at work again at the Westminster Hospital.

Mr. F. C. Dwyer succeeds the late Sir W. Stokes as professor of surgery in the Royal College of Surgeons of Ireland.

OUR PARIS LETTER.

To the Editor of the Medical Record.

COCAINE INJECTIONS: REMARKS BY TUFFIER—THEIR USE IN THERAPEUTICS: MARIE, DEBOVE, ACHARD—INJECTIONS OF MERCURIAL SALTS: BROCQ, BESNIER, SABOURAUD—QUININE IN CANCER—THE MICROBE OF BUBONIC PLAGUE; ITS REAL DISCOVERER—HAYEM'S TREATMENT OF GASTRIC ULCER.

Paris, April 22, 1901.

Sir: In connection with the letters written recently by Professor Reclus and Dr. Tuffier to the *Presse Médicale*, the following remarks made by Dr. Tuffier to the Society of Surgery seem to be a disclaimer of the fact that patients had died as the result of injections of cocaine. Dr. Tuffier said that he used a needle with a short point and made the injection above the sacro-lumbar space. The two-per-cent. solution was better indicated, as it was not necessary to inject so much. The injection should be done very slowly. Vomiting and headache were sometimes caused by this method, but no death had taken place during the operation, the eight deaths cited by Dr. Reclus being in no wise the result of the method used.

Cocaine as a therapeutic agent is talked about more and more. At a meeting of the Medical Society of the Paris hospitals, held on the 19th of April, Drs. Marie and Guillain spoke of a case of lumbago cured instantaneously by an intrarachidian injection of 5 mgm. of cocaine. The patient had begun suffering three days before the treatment was tried, and when seen found it difficult to walk and was obliged to stay bent forward. As in a prior case of sciatica 5 mgm. of cocaine were injected, and three minutes afterward there was a notable change. Two minutes later the patient was able to get up and dress without any help, and on returning home he found he was quite cured. Dr. Marie remarked, however, that in a case of scapulalgia, as well as in one of subacute rheumatism of the lumbar region, he had obtained no tangible result with this treatment.

In the course of the discussion which followed, Professor Debove cited the observation of a patient of his service, who was suffering from a severe attack of gastralgia such as is seen in locomotor ataxy, and who was instantly relieved by a simple lumbar puncture, by which 30 gm. of cephalo-rachidian fluid was removed. Professor Debove remarked that he had been led to try this treatment because he considered a large number of crises of visceral pain were due to an increase of pressure in the rachidian canal. Dr. Achard said he had tried this treatment for a case of abdominal zona in which some relief was obtained, and also for a man suffering from priapism accompanied by pain, who was cured by this treatment.

The treatment of syphilis by injections was the subject of discussion at the Society of Dermatology and Syphiligraphy. A case cited by Dr. Brocq gave rise to it. He had been trying a new specialty put on the market called cypridol, which is supposed to contain one centigram of biniodide of mercury for every cubic centimetre of sterilized oil, and when the third injection was made the patient, who was a woman aged thirty-one years, suffering from a papular eruption, complained of severe pain, and the gluteal region, where the injection had been made, became very much swollen. Later, escharification took place, and the piece of mortified flesh which came away was 13 cm. long, 8 cm. wide, and 5 cm. deep. Dr. Brocq stated he thought it best to be rather reserved in the use of injections in the secondary period of syphilis, and to employ them only in severe cases and especially in the tertiary period.

Dr. Barthélemy seemed to consider that such an accident must have been due to there being some effusion of blood, some vessels having been torn. He favored the method by injections. Dr. Besnier sided with Dr. Brocq, and said he considered the method was useless if not often injurious, as it seemed to cause such accidents as iritis in some cases. Dr. Gaucher said he preferred using soluble salts, and he did not care to make deep injections. Dr. Sabouraud remarked that the liquid used might be of some importance. He had found that oil caused in some cases ulcerations.

At a meeting of the Society of Neurology Dr. Allard said he had examined ten patients who were subjected to intrarachidian injections of a two-per-cent. solution of cocaine. In nine cases he found there was an increase in the faradic and galvanic excitability of the muscles and nerves. As for sensibility to the electric shock, he found that it was still present, which is the opposite of what has been said so far.

The use of quinine in the treatment of cancer has been again brought to the fore by Dr. Jaboulay at the last meeting of the Medical Society of Lyons. He presented two patients suffering from a recurrence of cancer of the breast, the tumor being accompanied by œdema of the upper arm. There was marked improvement in both cases by 1 gm. of quinine being given daily. The œdema diminished as well as the pain, and the movements became possible. In one case, in which there was an ulceration near the axilla, an ointment was used containing quinine in the proportion of 1:10. There was rapid transformation of the ulceration and the odor disappeared. In both cases the glands of the axilla diminished in size. In such cases 1 gm. of quinine should be given daily and replaced two days in the week by Fowler's solution. Some patients, however, can take it continuously without ill effects. When there is gastric intolerance, the drug should be given hypodermically, as the rectum does not tolerate solutions of quinine.

It has generally been thought that the first to discover the microbe of plague were Yersin and Kitasato, who were sent to Hong-Kong in 1894 by their respective govern-

ments. It must be remembered, however, that the description given by Yersin does not tally at all with that furnished by Kitasato. The microbe of Yersin is motionless, does not coagulate milk or cloud bouillon, is not colored by Gram's method, and is found specially in the lymphatic glands. All these characteristics are the reverse of what Kitasato described. To judge from a report published by Tatsusaburo-Yabé, surgeon in the Japanese navy, the microbe of Kitasato would seem to be a species of pneumococcus which is found when septicæmia exists. Yersin would therefore be the real discoverer of the microbe of the bubonic plague.

Gastro-enterostomy as a treatment of ulcer of the stomach is not looked upon with as much favor in France as two years ago. In a recent clinical lecture given by Professor Hayem at the St. Anthony Hospital, he said he would consider it useful in case there were symptoms indicating pyloric stenosis, but generally he preferred the medical treatment, which consists for Professor Hayem in the following indications: Absolute rest in bed, and suppression of all food by the mouth. The patient may be allowed to swallow daily from a quarter to half a litre of water daily, given at the temperature of the room. All food should be given by the rectum, which shonld be first washed out with an enema of water or oil, after which the following enema may be given two, three, or four times daily: A glassful of water, two large spoonfuls of peptone (salted), two yolks of eggs. All this should be well beaten up and given with a syringe. As for various inert or alkaline powders Professor Hayem considers it best to try to snppress their use. Gastro-enterostomy should be done only when there is extensive hemorrhage.

Progress of Medical Science.

The Boston Medical and Surgical Journal, May 9, 1901.

The Fevers of the Philippines.—Joseph J. Curry says that typhoid fever exists among our troops in the Philippine Islands to a considerable extent. The death rate is less than fifteen per cent., due in part to the early recognition of the disease as typhoid. The author reports sixteen cases of Malta fever, the clinical history of which was that of a long-continued fever with periods of apyrexia, not influenced by quinine administration in large amounts. Typhoid symptoms were absent; neuralgic and rheumatic symptoms were usually present with a general glandular hyperplasia. Malarial fevers are widespread, the types being the æstivo-autumnal, the tertian, and the quartan. Out of 20,000 medical cases, 4,643, or twenty-three per cent., were diagnosed malarial fever. Mosquitos are very thick and extremely active in the Philippines. There are many undetermined tropical fevers, which may be satisfactorily studied when the conditions in the islands resnme a peace basis. Hepatic fever sometimes occurs in Europeans and Americans, usually in the first year of their stay in the tropics.

Early Diagnosis of Typhoid Fever by Isolation of Bacillus Typhosus from Stools; Conclusions of Dr. T. Remy Based on the Use of His Asparagin-Lactose-Carbol Gelatin.—Calvin G. Page describes this process as used by Rémy, who in 1889 made thirty-one examinations of stools from twenty-three cases of typhoid fever, and isolated the typhoid bacilli from every case. Early in the disease they are present in relatively small numbers. They increase considerably during the second week, and may sometimes be almost the only bacterium present. During the third and fourth weeks the number diminishes steadily. The presence of the typhoid bacillus with its specific characteristics is the only sign that, taken by itself, will justify the clinician in making a certain diagnosis. It is also the only sign that cannot fail.

Some Reported Cases of Typhoid Fever Attributed to Contaminated Oysters, with Certain Facts Concerning this Means of Infection.—By Charles Harrington.

Means of Infection in Typhoid Fever.—E. N. Whittier reports a case of infection by means of contaminated oysters at Marion, Cape Cod.

The Widal Reaction in Typhoid Fever.—By George B. Shattuck.

New York Medical Journal, May 11, 1901.

Primary Chancre of the Nose.—W. Freudenthal, after a review of the general subject of extra-genital infection and an allusion to the rarity of primary infection of the nasal passages, gives the history of a case belonging to the latter category. The patient was a physician aged thirty-two years, who noticed a small sore on the right side of the nasal septum. The principal symptoms at first were a dryness and a closing up of the naris. One month later the occipital glands and those on the top of the head began to swell and ache. There was some fever and the case was at first regarded as one of influenza. The spot in the nose looked like the commencing perforation so often seen in those who pick the nose with the finger. The glands down the side of the neck began to swell, the sore became a definite ulcer, and gradually assumed the character of a specific lesion. Meanwhile the glands on the other side of the neck became involved. A rash later appeared and the disease ran its usual course. The physician, who had the habit of picking the nose, remembered having examined per vaginam a woman who later showed specific evidences, and it is probable that this was the mode of contagion.

Atonia Gastrica and a New Method of Treatment.—The therapy of this condition consists in the attempt to give tone to the abdominal wall or to find a substitute for the loss of tone in some kind of a bandage. A. Rose advocates for the latter purpose the use of rubber plaster, the preferable variety being the so-called Unna's zinc-rubber plaster or the india-rubber plaster with zinc of Dieterich. The strapping is applied as follows: A piece, of the average size of thirty-six by twelve inches, is cut as follows: The large piece is applied as tightly as possible around the abdomen, drawing it well upward, the two ends meeting or overlapping at the spine. The plaster should not include the crest of the ilinm, but should rnn closely along and above it. The support of the abdominal walls is made perfect by the additional application of the two side-pieces of the plaster, extending from the hypogastrinm over the ingninal and iliac regions and reaching also to, or near, the spine. In applying the side-pieces we may use considerable force.

Acute Strangulated Femoral Hernia on a Porto Rican Hillside.—By P. R. Egan. The writer, a United States army surgeon, narrates the case of an ambulance driver who was the victim of the accident named, the latter coming on while the ambulance was out on a mountain road several miles from a village. Taxis was applied without success. The patient was taken several miles to a village, where some chloroform was secured and taxis finally successfully tried. An old trnss was applied and in an honr the man was again at work. An operation was deemed unadvisable, as under the snrroundings it meant, in the doctor's opinion, sure death.

The Diagnosis and Treatment of Injuries of the Head.—J. H. Dunn enumerates the different classes of injuries and the symptoms peculiar to each, together with indications for treatment. Familiar ground is traversed and nothing especially new mentioned. Concerning the replacement of trephine buttons, the author notes two objections to the practice: (1) Especially in traumatic cases these pieces often nndergo necrosis and have to be removed, and when they thus delay union they excite connective-tissue proliferation and, in addition to failing in their object, leave a less favorable cicatrix. (2) Histological observations, after bone implantation, show that pieces of bone which have been separated entirely from their anatomical surroundings, when returned to their former place, or placed in another defect in the hnman skeleton, indeed may grow, yet in all cases undergo necrosis. For plates for skull defects he inclines to the common view that celluloid is the best material. In cases of rnpture of the middle meningeal artery, osteoplastic resection of large bone flaps has its advantages. The chisel is the best instrument for this purpose. Advocacy is also made of the use in surgery of the skull of the Gigli saw, for the following reasons: (1) Exceeding simplicity and cheapness; (2) very considerable rapidity; (3) the saw-cut is exceedingly fine, doubtless the finest that can be made by any method, and may be cut as bevelled as desired, so that the resected piece of bone fits back more accurately than if cut by any other method.

Tropical Abscess of the Liver.—E. F. Robinson calls attention to the fact that the acquirement by the United States of tropical possessions renders it necessary for American physicians to be on the lookout for diseases not hitherto brought to their notice. The paper is based upon personal experience in the Philippines. Natives rarely take the disease, but it is frequent among Europeans, whose mode of living leads first to amœbic dysentery, which is

followed by abscess of the liver. Of the author's thirteen cases five were single and eight multiple. The right lobe was most commonly affected. In only two instances was the left involved. Five cases of abscess of the liver came under his observation clinically: three were of multiple abscesses in which nearly the whole liver substance was destroyed; two were of large single abscesses. All five were operated on, and only one recovered. In tropical abscess the symptoms are of but little value in establishing diagnosis. We must rely on local signs and the detection of pus by aspiration.

Medical Treatment of Actinomycosis.—J. L. Sawyers relates a series of cases, the diagnosis in all but one being confirmed by the microscope. The author notes that the disease is frequent in agricultural communities, and lays down the following propositions: (1) That actinomycosis is not an uncommon disease. (2) That, when pure, it is a non-suppurative, afebrile, comparatively painless, slowly progressing disease. (3) That the clinical signs and symptoms are often pathognomonic. (4) That the club-shaped bodies, single and in asters, are often absent, the threads more frequently present, and the coccus-like bodies most constantly present. (5) That combined surgical measures and the administration of the iodide of potassium give the best results. (6) That iodide of potassium administered internally cures a large percentage of cases. And, finally, that the interstitial injection of iodide of potassium into the infected tissues exerts a strikingly salutary influence over the disease.

Remarks on the After-Effects of Operation for the Removal of Adenoid Tissue at the Vault of the Pharynx.—E. L. Shurly says that the untoward effects of these operations may be either immediate or remote. Under the former heading he includes hemorrhage, injury to the pharynx, reactionary inflammation affecting the pharynx, larynx, tonsils, ear and accessory cavities, and sepsis. Remote effects comprise subacute disease of the pharynx, chronic diseases of the ear, diseases of the accessory sinuses, and tuberculosis. Remarks are made under each of these headings.

Medical News, May 11, 1901.

Studies in the Bacteriology of Typhoid Fever, with Special Reference to its Pathology, Diagnosis, and Hygiene.—Philip Hanson Hiss, Jr., concludes that during the course of typhoid fever, usually after the first week, typhoid bacilli can frequently be obtained from the blood, spleen, rose spots, urine, and fæces, and in rarer instances, it is claimed, from the secretions or exudations of the mouth, throat, and lungs. After death they have been found in these and other locations and lesions, such as the lymphatic tissues of the intestine, the mesenteric glands, bone marrow, lungs, liver, gall bladder, kidneys, etc. The bacilli do not seem to thrive or live long in the circulating blood. But they can live and multiply at some of the points where they are deposited, thus forming bacterial foci in the tissues. Morphological examinations show that some of the lesions undoubtedly occur at points remote from the bacilli. It is probable, too, that the bacilli are closely associated with many of the lesions. Certain lesions probably occur only at points of localization of the bacilli. Typhoid fever is an infectious disease, during which various tissue changes take place, some necrotic, others hyperplastic. There is a close connection, in time at least, between the appearance in and disappearance from the intestinal contents of the bacilli and the appearance and repair of the intestinal ulcers. The organisms are only very rarely demonstrable in the stools before the first days of the second week, and disappear with the fall of the fever. When intestinal tissue destruction is most active, they can be isolated with great regularity. When they are continuously absent in typical cases, there probably is a scarcity or absence of intestinal lesions. The urine in a certain percentage of cases contains the bacilli. The urine should always be disinfected. The neglect of bacteriological examination of the urine often leaves unguarded a source of infection. Fæces should be disinfected at all stages of the disease. The expectoration should be disinfected, as well as all eating-utensils, etc., used by the patients.

Rupture of the Right Kidney; Nephrectomy; Recovery.—G. R. Trowbridge reports the case of a man aged forty-three years, a laborer. He was struck by a coal car and was brought five miles to the hospital. Immediately on admission he passed nearly one and a half pints of bloody urine. In about twenty minutes he passed three pints of bright arterial blood. The man was quickly prepared and a lumbar nephrectomy performed. The kidney was found torn about three-quarters through, and in its removal the rupture was completed, the organ being removed in two pieces. Several ligatures were applied, the wound was cleansed and closed throughout two-thirds of its extent, the remaining one-third being packed with iodoform gauze. The patient made an uninterrupted recovery. After-treatment consisted in sweating, decinormal salt solution injections, hypodermic stimulation, and considerable quantities of drinking-water. He now seems in perfect physical condition. The writer believes that exploratory operation should be done in cases of trauma of the kidney, for by this means alone is it possible to learn the extent of the injury.

Practical Food Prescribing.—By Floyd M. Crandall.

Philadelphia Medical Journal, May 11, 1901.

The Doctor's Fee; a Plea for Honorable Dealing.—John B. Roberts declares that if the sincerity, humanity, generosity, and truthfulness of an action cannot be readily seen, while its selfishness, cupidity, and necessary secrecy are recognizable, the physician may be quite sure that it does not meet the requirements of professional standards. The writer then speaks of various schemes such as the following: A certain mineral springs company has recently, it is said, offered its stock to physicians, so as to induce them to advocate the use of its water by their patients. Life insurance companies seem to the writer to have a code quite unlike that which the true medical profession believes to be honorable. He gives an experience in which he was asked to disclose professional confidences to one of these companies. Some doctors, it is believed, make a fee by accepting money from manufacturing drug companies for statements certifying to the excellence of their secret nostrums. These certificates are then published and distributed as advertisements. What is more despicable than the action of that operator who demands his fee before he will undertake the operation for which the patient is ready? Then, again, take the system of paying commissions to the family physician who refers cases to the consultant. The family physician should undoubtedly charge more than his usual fee when he has to call a consultation. In regard to the consultant, if the patient is unable to pay, it seems only right that he come to the assistance of his brother physician for a small fee, or for no fee if it is not obtainable. The amount of a doctor's fees should be based on his experience and skill. A well-to-do patient should be willing to pay a generous fee. But this fee should not be increased in the case of a wealthy patient.

The Etiology of Arrested Mental Development.—Pearce Bailey states that idiocy, imbecility, and feeble-mindedness are varying degrees of the same condition. They are all the psychological expressions of infantile cerebral pathology. Their causes include all factors that interfere with the development of the child's brain. They may be classed as: (1) Those occurring before birth; (2) those occurring at birth; (3) those occurring during infancy and childhood. 1. More than fifty per cent. of all cases of idiocy and feeble-mindedness are congenital, and in a large proportion of this number defective nervous systems on the parts of parents or near relatives exist. Tuberculosis in the parents as a cause of degeneration is well recognized. Alcohol is the most important factor in acquired degeneration. Hereditary syphilis causes organic brain disease in infants. The eradication of degeneracy has its brightest hope in increased education and better State care. Diabetes is really a moral disqualification for conception. The various fœtal diseases and twin pregnancy are also causes of feeble-mindedness. 2. The various factors which complicate delivery stand in prominent rela-

tionship to idiocy and imbecility. 3. All causes, whether traumatic, toxic, or nutritional, which act on the developing infant brain have a place in this category. Chronic alcoholism and its effects in infants are becoming better and better known. This comes from parents giving wine and beer to their offspring. The study of any one of these causes will be of use to those who desire children or to those who have them to care for.

Ephemeral Insanity, with Report of Two Cases.—Charles J. Aldrich reports these cases. The first was that of a girl aged eighteen years, who had always been well before. She awoke one morning with the most insane notions on religion. She thought the world was about to end, and she talked incoherently. In a few hours this condition passed away and she has never shown any signs of the same since, although two years have elapsed since the occurrence. The other case was in a man aged forty years. He was suddenly seized with the idea that two of his co-laborers were plotting to kill him. He was taken to the hospital, where he was kept quiet for a few days. He absolutely recovered.

A Preliminary Note upon Hydrocyanic Acid as a Disinfecting Agent.—John S. Fulton believes from the results of experiments that hydrocyanic acid may be found a reliable agent for house disinfection by boards of health, especially serviceable in maritime disinfection, and alone, or in combination with other gaseous germicides, very effective against certain infectious diseases. In bactericidal power hydrocyanic acid is inferior to formaldehyde, but the latter is not more effective against diphtheria bacillus and the non-sporulating bacilli generally. It offers a slight advantage over formaldehyde for house disinfection in that it is generated without fire. It seems evident that against organisms no hardier than bacillus diphtheriæ and bacillus typhosus, hydrocyanic-acid gas is about as effective as formaldehyde, though a greater amount of gas is needed, and perhaps a longer exposure. One gram of cyanide per cubic foot of space is probably the correct proportion. No claims for great power of penetration can be made for hydrocyanic acid as against bacterial life. A gaseous germicide with great penetrating power is as yet a chimera. Against animal life this acid has strong diffusive energy. It does not seem unlikely that hydrocyanic-acid gas may to a great extent meet the need of a gaseous germicide which shall also be destructive of animal life.

Some Remarks on the Inheritance of Acquired Immunity.—George Ogilvie reviews some experiments by Ehrlich on animals which show that the offspring may derive immunity from its mother in a twofold manner, by either the blood or the milk—that is, by the placental circulation or by suckling. It is self-evident that in these cases it is not the immunity which passes from the maternal organism to that of the child, but the antitoxin, and that the passive immunity of the offspring thus produced cannot be considered an acquired character transmitted by true inheritance. These results were obtained by experiments made on mice with vegetable poisons. Yet in rabbits and in guinea-pigs, as well as in mice, a certain degree of blood or placental immunity is conferred by the mother on the child with regard to both the tetanus and the diphtheria toxins. Ehrlich's experiments have of late been made use of to explain all sorts of real or imaginary phenomena of clinical medicine. In truth, however, up to the present day no clinical observations exist pointing to a similar transmission of immunity in the human race. If there is nothing to prove that immunity as an acquired character—that is, active or histogenic immunity—is ever transmitted to the next generation by true inheritance—that is, by the germinal cells—the placental or the suckling immunity also has, so far as we know, no exact parallel in human pathology. That such a thing as germinal transmission exists in maternal infection we can only presume from analogy, because, as said before, germinal and placental syphilitic infections do not differ in the nature or succession of the clinical symptoms they produce. If no clinical proof exists to show that placental immunity is ever transmitted by the germinal cells to the next generation, there still remains the possibility that such transmission takes place all the same, only to such a minute extent that it escapes detection by the rough and somewhat clumsy methods of clinical observation. As to the accumulation theory, until we have at least some clinical or experimental proof that infectious diseases lead by themselves to a gradually increasing immunity in the offspring, this theory as an explanation of racial immunity will remain an unsubstantial hypothesis.

The Treatment of Two Cases of Nerve Leprosy in which Recovery Took Place.—George Thin reports these two interesting cases. The first was in a boy aged eleven years, suffering from fully developed and severe nerve leprosy. This had afflicted him for seven years. The main line of treatment prescribed was the use of chaulmoogra oil, which was applied externally and given internally. This treatment resulted in a perfect cure, and thirteen years later he presented himself for examination, and the only evidence he showed of his once having had leprosy was the mutilation of the hands and feet, and the incomplete restoration of sensation on some parts of the limbs. The other case was in a youth. The treatment consisted in the external application of five-per-cent. pyrogallic acid, and the internal administration of a drachm of gurjun oil twice a day, and two minims of Fowler's solution twice daily. Later, the strength of the ointment was increased to seven and a half per cent., and so continued. As there was an idiosyncrasy against the arsenic, it could be given only occasionally and in small doses. This patient also made a perfect recovery.

An Unusual Symptom in Secondary Syphilis.—A. A Scot Skirving has noted the symptom of itching in the throat in secondary syphilis. One of the patients was in the habit of scratching his throat by swallowing entire portions of the crust of the "brodchen" which he ate. In both cases the itching appeared very shortly after the onset of the sore throat—about eight weeks after the appearance of the chancre. This symptom seems quite remarkable in these instances, since with the exception of small papular syphilides, specific cutaneous eruptions seldom itch much—often, indeed, not at all.

Whooping-Cough Cured by Irrigation of the Nares.—Ed. Marten Payne gives an account of his method of treating pertussis in a boy aged nine years. Ten to twenty ounces of carbolic lotion (1:40) were injected by a syringe through the nostrils, being allowed to go up one and down the other, the operation being repeated three times a day. At first the irrigation caused a good deal of sneezing and coughing and the ejection of considerable mucus. This soon wore off, and the cure was complete in about a week. These irrigations must be thorough to insure success.

Hibernation of Mosquitos.—E. A. O. Travers states that a large number of mosquitos—Culex pipiens—were recently found in a state of hibernation in a village near Bedford. They were discovered in a damp cellar during the last week in February. They were kept for some time at ordinary room temperature and were fairly lively, but would not bite, and seldom fed on fruit placed in their cage. They were all females, but they laid no eggs, nor did they show any further development.

The Lancet, May 4, 1901.

A Case of Recovery after Operation for Diffuse Peritonitis from Perforation of the Appendix.—By R. Coombe. The patient was a boy aged fourteen years. Operation was done on the fifth day of the disease. The abdomen was opened by an oblique incision reaching as far down as the deep epigastric vessels. On division of the peritoneum at the upper part of the wound, the operator came upon an abscess extending upward outside the ascending colon toward the liver. The pus, which had a strong fecal odor, was carefully sponged out of this. The edge of the omentum, which lay on the inner side of the wound between the large bowel and the parietes, was not disturbed at the upper part, as there was a little gluing together of the peritoneal surfaces, but in the direction of the pelvis there was not the faintest attempt at any barrier and the fingers passed right down into the pelvis to the roof of the bladder, a large quantity of dirty brown-tinted blood welling up as the coils of intestine were separated. This fluid was sponged away as it welled up, and when this ceased the sponges were continually passed down into the pelvis until they returned dry. Two large drainage-tubes were then inserted, one going to the subhepatic pouch, the other down into the pelvis. The appendix itself was not seen. During convalescence an abscess formed in the scrotum; otherwise recovery was uneventful.

Some Further Investigations upon Rheumatic Fever.—By J. Poynton and A. Paine. The article is in continuation of previously reported observations of the authors upon the bacteriology of rheumatic fever. The first part of the paper refers to the isolation of a certain diplococcus from rheumatic nodules. The following is a summary of the writer's experiments: (1) They have demonstrated the diplococcus in three rheumatic nodules taken from two cases of rheumatic fever; (2) they have isolated the diplococcus from the nodule in one instance in pure culture; (3) intravenous inoculation of this culture has produced valvulitis, pericarditis, and polyarthritis in a rabbit; (4) they have isolated the diplococcus from the joint exudate of this rabbit; and (5) the nodule is looked upon as a highly characteristic manifestation of rheumatic fever, therefore they conclude that this investigation lends strong support to the contention that this diplococcus is a cause of rheumatic fever. Other points touched upon are the pathology of rheumatic chorea, the occurrence of the diplococci in polymorphonuclear leucocytes, and the incubation period of rheumatic fever. They ask, "Is fever a primary phenomenon in rheumatic fever or is it secondary to the local lesions only?" and incline to the latter view. They also discuss the experimental production of morbus cordis.

On Serous Vaccinia in Connection with Cretinism and Rickets.—By Robert Kirk. Four cases are given in detail, the constitutional states being respectively myxœdema at the age of thirty-four years, subsequent cretinism or juvenile myxœdema, serous vaccinia occurring in six members of a rickety family, one child being a cretin, and serous vaccinia with symptoms probably indicative of a myxœdematous tendency; spasmodic asthma at the age of six years. The author inquires, Is the thyroid specially concerned in the production of serous vaccinia and serous types of other affections? He would answer that the evidence seems to show that such is the case in many instances, although it would be hard to speculate on other factors which may sometimes co-operate. It would appear, further, that the condition of the gland in such cases is one in which it is prone to atrophy from exciting causes which would otherwise prove inefficient.

Note on the Results Obtained by the Anti-Typhoid Inoculations in Egypt and Cyprus during the Year 1900.—By A. E. Wright.

	Uninoculated.	Inoculated.
Average annual strength	2,669	720
Number of cases of enteric fever	68	1
Number of deaths from enteric fever	10	1
Percentage of cases calculated on average annual strength	2.5	.14
Percentage of deaths calculated on the same basis.	.4	.14

These figures testify to a nineteenfold reduction in the number of attacks of typhoid fever and to a threefold reduction in the number of deaths from that disease among the inoculated.

French Journals.

Movable Liver.—Maurice Soupault believes that there are two chief etiological factors which may contribute to this condition: (1) The liver is movable because it is not well supported. (2) The liver is movable because it is deformed. Hepatoptosis from looseness of the ligaments is scarcely observed before the age of twenty years. The influence of sex is evident. In seventy-four cases, sixty-seven were in females. Pregnancy, especially when oft repeated, is among the determining causes; laparotomy, abdominal tumors, obesity, and certain general maladies like typhoid fever also play a part. In certain cases there is no local or general cause which can be definitely found, but there seems to be a general disturbance of nutrition characterized by a tendency to relaxation of the tissues—especially the fibrous tissues which certain authorities claim as the cause of this trouble. Others believe that the tight corset is most potent as a cause. Besides these, hard work, violent cough, and vomiting are sometimes at fault. As to the deformity of this organ, the corset undoubtedly has its share in producing it; as does a tumor adherent to the liver tissue or an abnormal gall bladder. In the treatment of floating liver, surgery offers great assistance. It is indicated when the mobility of the liver is so great that dorsal decubitus does not reduce it; when serious troubles result from this condition, *e.g.*, stenosis of the pylorus; when, after sufficiently prolonged medical treatment, general troubles still persist as well as great pain. Less radical treatment consists in attention to the general state of nutrition. Repose in bed for some days is often beneficial. Electricity is used, also a support for this organ in the form of a binder. Hydrotherapy is also made use of. The digestive disturbances should be most carefully looked after—many of which are neurasthenic in variety. Troubles of nutrition should be treated. The results of surgical treatment have been very brilliant.—*Gazette des Hôpitaux Civils et Militaires*, April 13, 1901.

Anæsthesia by Cocaine.—G. Juillard states that he prefers ether as an anæsthetic. He believes that statistics do not give all the fatal cases in the administration of chloroform, and it may be the same way with cocaine. The status of this alkaloid cannot yet be determined, since statistics concerning it are not sufficiently complete. Great care must always be taken with alkaloids, especially when they are injected directly into the central nervous system. The writer has had over nine thousand cases of anæsthesia with ether without accident. Ether is the least dangerous of all the anæsthetics. Nevertheless, the analgesia of cocaine has a great advantage; it permits the operation to be performed without pain and with the preservation of complete consciousness, which is sometimes most valuable. The intrarachidian method will not become the general method, but will probably remain the exceptional one.—*Revue Médicale de la Suisse Romande*, April 20, 1901.

Concerning the Technique of Operation in Appendicitis (Appendicitis in the Abscess Stage).—Phocas concludes that this operation is one which offers a certain mortality. This mortality can be diminished by limiting the operation to the mere opening of the abscess without hunting for the appendix or touching the adhesions. But in these cases the operation is incomplete and brings a tendency to post-operative accidents—fistula, hernia, recurrence. It is better to run these risks, however, than to expose the patient to the risk of death. Therefore, operation should be confined to the opening of the abscess. In every possible case it is better to wait and perform the operation later after the patient has recovered, if it is then deemed advisable. In this way the patient recovers without surgical treatment, and later he can submit to the operation, which can then be performed without danger.—*Le Nord Médical*, April 15, 1901.

Aphthous Fever and its Treatment.—M. Nocard, according to Jarre, reports that when this disease is scourging the country it is well to give the sickness to all the animals in the infected stable at one time. This can be done by swabbing the mouths of the healthy animals with the sa-

liva of those affected. The duration of the disease is much diminished, for the buccal form of the affection is the least grave. The affected animals must have their mouths washed with antiseptic lotions, as well as the udders and the feet. This should be repeated as often as possible. Any food requiring long and complete mastication should not be given. Food should not be forced on the animals. Laxatives and diuretics should not be given. The udders should be emptied of milk, which should be boiled before being used by man or animal.—*Bulletin de l'Académie de Médecine*, March 26, 1901.

Cancers of the Large Intestine, Rectum not Included.—According to Goullioud, cancers of the large intestine present anatomical conditions favorable for surgical intervention. These conditions are: (1) The patients are as a rule operable when they come to consult the surgeon, because the symptoms of this trouble are very precocious. (2) The tumors are movable, often extremely so. This characteristic is due to the fact that they are developed at the expense of the mucosa, the muscular tissue forming a sort of barrier against them. If a large resection is made, including the mesentery, at least the first set of lymphatic ganglia can be raised with the tumor. Surgical intervention suppresses all the painful symptoms—vomiting, pain, and phenomena of obstruction.—*Lyon Médical*, April 21, 1901.

Pyonephrosis of Typhoid Origin.—Garnier and Lardennois conclude that typhoid fever can cause renal suppurations assuming the form of pyonephrosis frank or latent. It is only during convalescence that the diagnosis can be clinched. It will be founded on the existence of pain in the lumbar region, the presence of a tumor of the kidney more or less large, and in certain cases an intermittent pyuria. The treatment is, before all else, surgical. It should be prompt. Nephrotomy ought to be sufficient and should give excellent results with few risks. But nephrectomy will often be indicated secondarily when there are numerous abscesses badly drained, and if the operator is certain of the integrity of the other kidney.—*La Presse Médicale*, April 13, 1901.

Deutsche med. Wochenschrift, April 18, 1901.

An Unusual Case of Hysteria.—J. Arneth describes a very dramatic case of hysterical spasm of the depressors of the epiglottis in a girl aged twenty-three years, whereby this appendage was maintained in close apposition with the glottis so that expiration was difficult and inspiration almost impossible, and a condition of extraordinary dyspnœa resulted. Occurring at intervals of from a few minutes to half an hour were attacks of complete apnœa with unconsciousness and every indication of imminent death from asphyxia. All therapeutic measures, suggestion, electricity, baths, etc., produced not the slightest effect till some liquor ammonia was held under the patient's nose at the conclusion of one of the attacks. The effect was instantaneous; the respiration became better almost immediately, and it was found that through the irritation of the ammonia so much congestion of the epiglottis had been produced that it was impossible for it to resume its former valve action. Complete recovery finally followed the use of intimidating measures, the patient being threatened with a repetition of the introduction of the stomach tube, which was intensely disagreeable to her, unless the attacks of dyspnœa ceased.

Contributions to the Knowledge of Cardiac Neuroses.—A. Schmidt has observed that cardiac neurasthenics are especially prone to exhibit fluctuations in pulse frequency and force during forced respiration. These may in part be explained by the effect of the changes in intrathoracic tension so produced acting on a vascular system under low pressure, but not wholly, for the momentary complete cessation of pulsation, change in form of the individual pulse curve, and the appearance or disappearance of arrhythmia require some more general cause for their production. Löwit has suggested that there may also be reflex nerve influences originating in the distended pulmonary alveoli, and the author concurs with this view. A second point to which he calls attention is the zone of distended venules marking the limits of the attachment of the diaphragm and the cardiac dulness, and most often observed in those suffering from chronic cough. This appearance is also frequently associated with heart neuroses, and the author thinks has a causal relationship with the abnormal cardiac mobility and habitual constrained position at the writing-table that are so often found in this class of patients.

The Treatment of Lobar Pneumonia.—Hornung gives the result of his observations, which show that damage of the vasomotor centre is followed by acute dilatation of the heart. Such weakening, particularly of the right ventricle, is one of the greatest dangers in pneumonia, in which the toxins of the disease itself are continually tending to break down the integrity of the vasomotor centre, and therefore chloral, ether, and most of all alcohol, which have this same property, are to be wholly condemned, for since the formation of the specific pneumonia poisons is out of our control it is of the greatest importance not to augment its action by artificially introduced toxic agents. Even in alcohol habitués, when it is thought that the drug must be continued to obviate the occurrence of delirium, repeated observation has shown that the only rational plan is to cut off the stimulant and substitute plentiful feeding, for the alcoholic delirium is simply a manifestation of inanition and must be combated as such. Of other stimulants, in spite of contrary opinions, the author holds that digitalis is not so slow in its action as is generally believed, and that though the typical pulse may not appear for several days, still a considerable reduction in size of the heart occurs speedily after the first dose. Camphor is highly praised as a rapidly diffusible stimulant. A heart tonic of undoubted value is to be found in cardiac faradization, which may be performed by placing one pole of an ordinary induction coil over the heart, while the other is passed over as much of the surface of the body as possible for ten minutes at a time. The effects of this electrization are manifold, for the vasomotor centre is stimulated, the rapidly repeated contractions induced by the current produce a very desirable form of massage, almost a "cell-massage," whereby circulation is facilitated, and finally general muscular tone is stimulated.

The Duration of Disability after Internal Disease.—R. Landau says that in considering internal diseases from this point of view they may be divided into acute and chronic, the former being further subdivided into febrile and afebrile. No hard and fast rules are possible, but it may be said that all patients with pyrexia, and for at least a week after its disappearance, are incapable of working, but the nature of the disease, the length of duration of the fever and its height, the complications and possible sequelæ, especially those affecting the heart, as after diphtheria and influenza, the necessity for continuing dietetic precautions, as after typhoid, the severity of accompanying pain, insomnia, etc., all need to be taken into account. Furthermore, the patient's age, sex, constitution, heredity, and the nature of his employment are also of great importance. Acute afebrile diseases usually disable only as long as the symptoms are present; for example, as soon as the pain and nausea of an acute gastritis have vanished and the appetite begins to return, the occupation may be resumed. Chronic conditions require much thought in their management and are very varying in the degree of disability they produce. In general, those subject to acute exacerbations, as pulmonary tuberculosis, need more careful watching, and more success is to be obtained with those doing their work at home than with factory hands, with whom any discrimination in the severity of the labor is usually impossible.

Acute Serous Meningitis.—J. Hegener reports two cases running almost parallel courses. Both patients were young men who since childhood had suffered from chronic middle-ear disease, which at the time of admission was undergoing an exacerbation and accompanied by signs of meningeal involvement. In the one case immediate improvement followed the clearing out of the diseased areas by a mastoid operation together with an exploration of the subdural space and of the brain itself for abscess. During the succeeding days the dressings were saturated by the enormous serous exudate of cerebrospinal fluid, which persisted for nine days and then ceased, the patient making a perfect recovery. In the other case at the first operation the meninges were not explored, and the improvement that followed was only temporary, so that a week later the temporo-sphenoidal lobe was exposed by an osteoplastic flap and the membranes were incised. No pus was found either in the meninges or the brain substance, but a copious serous exudate continued to flow for three weeks after the operation. It is interesting to note that in this case, nine days after the drainage of the subarachnoid space had been instituted, choked disc developed and persisted for four weeks, evidently pointing to a progression of the disease after it had been checked at its starting-point.

Disability in Skin Diseases.—J. Neuberger, writing from the standpoint of the lodge physician, states that in most cases of skin disease the patient is to be allowed to continue at his work. The principal essential is accurate diagnosis, whereby an innocent itching affection like a universal seborrhœic eczema is differentiated from a more

serious disease, such as lichen ruber, for the former does not require the complete rest that the latter does. Another point of importance is the selection of appropriate plans of treatment, for in case of the laboring man forms of dressings, applications, etc., that would ordinarily be employed have to be discarded in favor of, perhaps, not quite so efficacious but less hampering measures. The sort of work performed has also to be considered; a standing occupation is bad for patients with leg ulcers, for example, and sometimes a change of trade is necessary before a cure can be effected, as in some cases of eczema. Finally, the point of infectiousness must be thought of, and the possibilities of the transmission of the disease to the patient's fellow-workers not overlooked, though there are but few conditions that require more than ordinary care in the use of utensils, towels, etc.

Infectious Aortitis with the Formation of Aneurism.—Peter F. Holst reports the case of a young man suffering from gonorrhœa and arthritis. This condition improved under treatment. He was taken with chills at irregular intervals, his temperature rising to 104° F. Physical examination revealed an enlarged spleen, hemorrhagic nephritis, and a diastolic murmur at the base of the heart. After a sudden attack of hæmatemesis the patient died. The autopsy revealed a sacculated aneurism about the size of a hen's egg, near the aortic valves, and a smaller one just above it. The calibre of the aorta was narrowed by a diaphragmoid projection. Microscopical examination showed a diffuse cellular infiltration in the media and adventitia of the aneurism, together with many diplococci and cocci in chains stained by Gram's method. The author believes this to be a case of non-luetic, infectious aneurism following gonorrhœal rheumatism.

A Case of Purpura Fulminans.—This is reported by P. Voss. A five-year-old girl had been ill about a week, complaining of pains in various parts of the body which were taken to be rheumatic. For the first few days she had been up and about, but for two or three days had been confined to the bed, complaining increasingly of the pains. She was well nourished but pale. Each of the lower extremities presented a spot the size of the palm of the hand, of purple color, and there were also smaller spots with a parchment-like feel, and surrounded with a red circle about one line in width. Spots of similar color appeared later on the soles of the feet. There was no albumin in the urine. The child was admitted to hospital, but died the same night.

A Case of Purpura Fulminans.—Thomas Bargen reports the case of a child aged two years who was suddenly taken ill, and covered with ecchymoses. Death occurred in two days. At the autopsy there was found a condition of general anæmia, with swelling of the tonsils, glands of neck, and bronchial glands. Abundant quantities of streptococci were obtained from the spleen, the blood of the heart and glands, and sections of mucosa from the pharynx and the glands. Inoculation with these cultures produced death in animals. The author considers the case to have been a violent streptococcopyæmia accompanied by the hemorrhagic diathesis.

THE AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

Fifteenth Annual Meeting, Held at Old Point Comfort, Va., April 30, May 1 and 2, 1901.

THE PRESIDENT, SAMUEL ALEXANDER, M.D., OF NEW YORK, IN THE CHAIR.

Address by the President.—DR. SAMUEL ALEXANDER, of New York, after calling the attention of the association to the death of Dr. Fessenden N. Otis, a former president of the association, presented for their consideration the subject, "The Treatment of Intra-Peritoneal Traumatic Rupture of the Bladder by Laparotomy and Suture." Including his own experience, this report comprised forty-five cases with twenty-three deaths and twenty-two recoveries. The first part of his paper was chiefly historical, and then followed a critical examination into the causes of death. He next took up the etiology of intra-peritoneal rupture. The following questions were then considered:

1. How can we prevent delay in operating upon these cases? He believed that valuable time was lost because of the routine methods usually employed in order to insure positive diagnosis. Much time was lost in differentiating between an intra- and extra-peritoneal rupture. The injection test and the inflation test he believed to be decidedly harmful. He did not see the necessity of making a positive differential diagnosis between these two conditions, for both required operation. The operation should be begun by exploring the prevesical space; if this was found to be healthy the incision might be extended upward and the abdominal cavity opened.

2. How shall we treat the peritoneal cavity to obtain the most thorough asepsis? He thought the best results could be obtained by most thorough irrigation of the cavity with hot decinormal saline solution, not only at the beginning of and immediately after the opening of the abdominal cavity, but repeated after the rent in the bladder had been sutured.

3. How can we most effectually close the bladder wound? The question was not so much the material of which the suture was made as the manner in which the suturing was done. In the case he reported the material used was silk, and the rent was first closed with a layer of interrupted Lembert sutures, and these were reinforced by a second layer of mattress sutures.

DR. J. P. BRYSON, of St. Louis, said that in intra-peritoneal rupture he began the operation by slitting the mucous membrane, and dissecting away a small part of the muscular coat, so that when the sutures were introduced and drawn taut they would throw the mucous membrane into ridges and make really a valve.

DR. JAMES BELL, of Montreal, said that infecting lesions in the lower part of the abdomen spread upward relatively slowly, and he thought there was some risk of disseminating infection by general irrigation. Swabbing offered certain advantages.

DR. CABOT, of Boston, was apprehensive as to the use of certain ligatures on account of the liability to stone formation. In bad cases of rupture he would be inclined to use silk ligatures because they held; in extensive ruptures he would use catgut, but outside the catgut he would use silk in order that the strain might be taken off.

DR. CHISMORE, of San Francisco, reported an instance of a patient who had been operated upon for inguinal hernia some five years before the speaker saw him. He came under Dr. Chismore's care for stone in the bladder. The speaker removed the stone and

then found two silk ligatures. He then learned that the surgeon who had operated on the hernia had made a mistake and excised a portion of the bladder and sewed the incision up with silk ligatures. The man recovered and the silk ligatures had remained.

Report of a Case of Nephrectomy for Adeno-Carcinoma; with Remarks on Combined Cystoscopy and Segregation as a Guide to the Earlier Surgical Intervention.—Dr. John P. Bryson, of St. Louis, made a report of such a case. Looking to the history and the physical examination up to the point of cystoscopy, there was only the absence of a vesical symptomatology to justify exclusion of the bladder as a source of the hemorrhage, and this was far from exclusive. A vesical papilloma situated behind and above the trigone might have produced the same kind of manifestation. Urethral and prostatic hemorrhage was easily excluded, and the vesical symptoms accompanying the entire hemorrhage were referable to the clotting of blood in the bladder. There was entire absence of a history of renal symptoms during the whole attack. The first satisfactory step in the location of the source of mischief was in cystoscopy. This revealed a normal bladder and two normally situated ureteral orifices. While it was true that the injection of the left orifice and the gradual clouding of that part of the cystoscopic field as the observations progressed raised a strong suspicion of the source of the bleeding, and while it was equally true that subsequent and more extended observation might have given more conclusive evidence in the way of a blood spirt when the bleeding was more active, the real and practical value of the cystoscopy was in excluding the bladder as the source of the bleeding and preparing the way for a segregation. Segregation with the Harris instrument was easily and almost painlessly done, and gave evidence of the highest value in determining the justification, not to say the necessity, for doing an exploratory operation. In looking at the tables presented he thought that one could easily conclude that (1) the two specimens came from the same kidney; (2) the right kidney was functionating normally; (3) the left kidney was the source of the hemorrhage, and (4) the left kidney was in such a state of irritation as to determine a unilateral polyuria, albuminuria, mild bacteruria, and pyuria. The lower specific gravity, the greater quantity, and the amount of albumin out of proportion to the amount of pus and blood, tended strongly to eliminate the ureter and pelvis as the seat of the mischief and thus to carry it quite into the renal parenchyma. It would be noted that no tests were made to determine the epithelial adequacy and the renal permeability—omissions which might to-day be open to criticism. With cryoscopy he had not yet had much experience, but he instituted a phloridzin test with a lively appreciation of its practical value. In at least three cases it had been of excellent service, and he was impressed that it was, in connection with the separation of the urines (F. Tilden Brown), capable of greatly enlarging our field of direct observations of renal capability. In the effort to determine the relative adequacy and permeability we had been accustomed to give the greater weight to the quantity and specific gravity of the separated urines. The ascertaining of the relative functional capabilities of the two kidneys did not give us all the information required in regard to the kidney which was to remain and do the whole work of excreting. The matter of the relative excretion of urea might have been too much overlooked, but we could not readily tell how well a kidney might be doing until we knew what the blood brought to it; and the antecedents of urea in the blood were, so far as we knew, influenced by so many and varying conditions that it was difficult to bring the subject within a working formula. Cryoscopy might be of service in this matter, but the phloridzin test appeared to have the greater value. If relative urea excretions varied so greatly as to affect the value of the observation, which covered but one-forty-eighth of the time of daily kidney function, the permeability was quite as much affected by varying conditions of the other viscera. The heart, arteries and lungs, the brain and nervous system, and organs concerned in digestion, all had to do with the permeability of the kidney. It would be but a one-sided pathology and too narrow specialism which should fail to take into account the relationship of the condition and functional activity of other important organs as their changes affected the kidney and its work.

The Value of the X-Ray in the Diagnosis of Renal Stone: Report of Four Cases.—Dr. Paul Thorndike, of Boston, made a brief report of these four cases, not in order to show beautiful *x*-ray plates of kidneys containing calculi, but because the cases were studied by the same people under the same conditions and showed results, partly negative in character, which the writer deemed of enough interest to justify their presentation. It seemed to be true that stones which contained mineral salts were much more readily photographed than others, and yet two of these calculi were made up of layers of uric acid, and in both cases distinct shadows were evident, while in one of them the stones were shown with considerable clearness, probably due to the admixture of urates in the former and of calcic phosphate in the latter case. It would seem that there was something to expect from *x*-ray photography in connection with the diagnosis of renal stone; for in those cases, even when there was every clinical reason for thinking that a stone if present was composed of uric acid, it evidently needed only a small amount of urates or some other mineral salt to give a shadow which, although it did not show for much on the plate, was still capable of being recognized with some degree of precision by properly experienced observers. In conclusion he referred to the various methods of exploring a kidney. Some time ago he was present at a lecture and heard reference made to the lifting the kidney on to the loin and then splitting it along its convex border in such a way as to expose its whole interior to easy examination. The lecturer said he had never been able to do this, and had tried many times. The speaker's experience with renal cases was not large (probably fifteen cases would cover all the strictly exploratory operations he had ever done, not of course, including among them the operation for drainage of pus); but he had been able to carry out this exploratory technique in six instances and had never had the least trouble from hemorrhage or otherwise, either during or at any time subsequent to the operation. In some stout people it was a practical impossibility to carry out this method of investigation, and efforts to do so should not be persisted in; but in many patients of average weight the procedure was not difficult and could be accomplished with no undue tension upon the renal vessels. It was the author's belief that in cases in which it could be done it was far less likely permanently to injure the renal tissues than the less certain and far less satisfactory method of exploring the kidney with the finger through an opening made in the kidney substance or in the convex border. It was the author's practice to endeavor so to expose the kidney in every exploratory operation he performed, and it was satisfactory to realize how often it was easily possible to do.

Rupture of the Urethra: a Report of Cases.—Dr. James R. Hayden, of New York, read a paper in which he reported three cases, as follows:

Case I.—A man, thirty-six years of age, about thirty hours before admission to Bellevue Hospital and while in an intoxicated condition, was kicked in the peri-

neum. When he awoke the following morning he noticed blood on his shirt, and a slight bloody discharge from the meatus. On attempting to urinate he had an intense burning pain in the glans, and a feeling as if the urine were "leaking" into the perineum and penis. The stream was small, forked, and dribbling, and the patient had to strain for some time before starting it. Urination caused such severe pain that he broke out into a profuse sweat and fainted. He finally became so weak and exhausted that he entered the hospital for relief.

Examination on admission. The perineum was greatly swollen, tender, fluctuating, bluish-black, and abraded in places. The prostate and adjacent parts appeared normal by rectal touch. Slight bloody discharge flowed from the meatus. The urine was tinged with blood and contained bloody shreds, but was otherwise normal. No stricture was present. The bulbous portion of the canal was tender, bled freely, and felt roughened and lacerated when the bougie à boule was introduced. There was some compressor spasm, readily overcome by pressure.

Diagnosis and treatment. A diagnosis of rupture of the bulbous urethra with beginning extravasation of urine was made; the patient was etherized, and an external urethrotomy was made in the usual manner. The perineal tissues were found extensively infiltrated with blood clots and a thin bloody fluid having a distinctly urinous odor. The bulb of the corpus spongiosum was crushed into a bleeding and oozing mass of tissue, the bulbous urethra having ruptured longitudinally in many places on its floor, while its roof remained uninjured. The clots were turned out and all bleeding points ligated. A full-sized sound was passed and the bladder irrigated and drained by a large perineal tube which was removed permanently on the fifth day, and full-sized sounds were passed every day until the perineal wound was closed. The patient left the hospital on the twentieth day, the urine then passing normally by the meatus. No attempt at suturing the urethra was made on account of the contused condition of the tissues and the multiplicity and nature of the wounds.

Case II.—The patient, thirty-seven years of age, twenty-four hours before admission to the hospital, while at work carrying a fifty-pound weight on his shoulder fell ten feet, landing astride a two-inch gas pipe. On standing up he felt wet about the genitals, and on inspection found that he was bleeding freely from the meatus, but he had little pain. He went home in a street car and called in a physician, who failed to enter the bladder after a prolonged and painful instrumentation; then, in order to stop the hemorrhage, he tied a bandage around the penis.

Examination on admission. The patient was weak and anæmic, but not in much pain, except that due to urinary retention. The prostate and neighboring tissues were apparently normal by rectal feel. The anterior abdominal wall was very tense and rigid, and the bladder greatly distended. The penis was so tightly bandaged that it caused marked swelling of the glans, which looked almost gangrenous. When the bandage was removed a surprisingly large amount of blood spurted forcibly from the meatus, but even then he was unable to urinate voluntarily. The scrotum and perineum were greatly ecchymosed, the latter being distended, tense, and fluctuating.

Diagnosis and treatment. A diagnosis of rupture of the urethra with urinary extravasation was made, and the patient prepared for operation. Soft-rubber and silk catheters passed as far as the bulbous urethra when they apparently left the canal and entered the perineal tissues. A No. 20 F. silver catheter passed into the bladder by its tip being kept close in contact with the roof of the canal, which was apparently intact. Forty-two ounces of bloody urine and many clots were evacuated and the bladder was irrigated with hot saline solution, several ounces of which were left in. Hemorrhage from the meatus was quite free during these manipulations. An external urethrotomy was then done, the silver catheter being used as a guide. The perineal tissues were filled with bloody urine and clots, and oozing freely. When the bleeding was stopped and the parts were dried, a longitudinal rupture about two inches in length could be seen in the floor of the bulb of the urethra, whose edges when retracted exposed the silver catheter, which was then removed. A full-sized sound was passed to the bladder, which was irrigated and drained by a large perineal tube as in external urethrotomy. The perineal wound was left open and lightly packed with gauze. On the fourth day the perineal tube was removed permanently, and a No. 30 F. sound passed to the bladder. On the twelfth day the wound in the urethra was cicatrized, all the urine passing by the meatus after that day. The perineal wound was closed at the end of the third week, the patient remaining in the hospital for several weeks for irrigations, sounds, and observation. The walls of the urethra looked so swollen and boggy that no attempt at closing the rent in the canal was made. At present, a little over a year since the operation, urination is normal, the patient taking a full-sized sound with ease.

Case III.—The patient, thirty years of age, about twelve hours before admission to the hospital, and while intoxicated, landed astride a narrow board. Six hours later he found his underclothes stained with blood, and the meatus sealed with a dry clot, on removal of which urination was free but painful, and followed by bleeding, which so frightened him that he entered the hospital for relief.

Examination on admission. There was a slight and constant oozing of blood from the meatus. The urine was tinged with blood, and contained a few light bloody threads and flakes, but was normal in other respects. Urination was free but painful. The perineum was ecchymosed and slightly swollen and tender, but there were no local points of tumefaction or fluctuation. The prostate and surrounding structures appeared normal by rectal feel. A large rubber catheter entered the bladder with ease and drew clear urine. The urethra felt normal, although the bulb was sensitive.

Diagnosis and treatment. A diagnosis of rupture of the bulbous urethra without extravasation was made, and the patient was placed in bed, and given boric acid and hyoscyamus internally. He was catheterized at regular intervals with a soft-rubber instrument, and the urethra very gently and sparingly irrigated at these times with a warm sterile alum solution. The perineum was covered with a cold bichloride dressing and the temperature was taken regularly to keep informed as to the necessity for external urethrotomy and vesical drainage. All bleeding stopped on the fourth day; the urine was clear, and the perineal swelling had disappeared. The temperature remained normal since admission. On the fifth day the patient was up and about, and passing a clear urine in a normal manner. On the tenth day he left the hospital at his own request, as he felt well and was anxious to resume his occupation.

Inversion of the Tunica Vaginalis for Hydrocele.—Dr. Robert H. Greene read this paper, and said that, within the last ten years, a new operation for the radical cure of hydrocele had originated in France and its use was being advocated by a number of surgeons at the present time. It consisted in an inversion of the tunica vaginalis. About one month ago he operated upon a case of hydrocele by this method instead of the Volkmann method, the one he usually employed.

This had been called Longuet's operation by one writer on the subject, and was apparently called by the Germans Winkelmann's operation. This case was his first, the patient being an old man with an extensive hydrocele of the tunica, accompanying three small hydroceles of the cord. No complications followed. It was very difficult to say to whom the credit of having first performed this operation should be given. Dudley Tait, last March, gave a clear description of the operation, with references. It was difficult to understand why the name of Longuet should be given to the operation, for with the exception of Vautrin the credit of having reported any number of cases as first operated upon by this method belongs to Jaboulay, who began to operate in 1894 and whose cases were reported by Berard on March 24, 1895. Since 1896 several French surgeons had reported cases. In Germany Winkelmann published a paper in 1898, giving the history of twelve successful cases operated upon by this method, but he did not refer to the French surgeons as having originated it. Dr. Greene then gave a somewhat liberal translation of Winkelmann's description:

"An incision is carried down to the sac of the hydrocele. The incision of the sac is 3–4 cm. long from above downward, more toward the upper than the lower pole. After the hydrocele fluid has escaped the testicle is drawn completely out, so that the entire tunica vaginalis proper is turned inside out. The incision in the tunica then comes in relation with the insertion of the spermatic cord into the testicle, which incision may be shortened by a suture or two, so that the testicle cannot return through the opening in the tunica. The tunica and testicle are replaced in the scrotum, with the result that the entire serous surface of the tunica vaginalis proper faces outward toward the loose connective tissue of the tunica vaginalis communis, with which it may soon become fused, the testicle lying outside the tunica, between the tunica and the scrotal wall. This bloodless operation is completed by closure of the external wound in the scrotum. In the majority of cases the testicle is dislocated upward as the result of the operation."

Drainage was not required. The only complication mentioned by any of the writers on the subject was the one mentioned by Winkelmann, who says that there might follow "a slight periorchitic swelling, due probably to the saturation of the loose connective-tissue interspaces with the secretion of the serous membrane, which may persist for some time." This same method had been tried for hydrocele in connection with operations for hernia, and operations for varicocele could be performed at the same time. This operation could be performed for double hydrocele by means of a single scrotal incision, followed by an incision through the membrane separating the two sides of the scrotum. Winkelmann did not consider it necessary to confine his patients to bed.

"Conclusions. 1. This is an easy operation to perform, and that it results in the cure of the hydrocele seems undoubtedly true. 2. The fact that so many operations have been recorded with the history of no unfavorable result as regards suppuration or neuralgia of the testis offers pretty conclusive evidence as to the safety of this operation from the above complications. 3. The effect it may have in causing atrophy of the testicle or changes in the function of that organ is a subject concerning which clinical data, extending over a period of time, are necessary before final conclusions can be drawn."

A Case of Unusual Bacillus or Abnormally Behaved Gonococci.—Dr. J. P. Tuttle, of New York, described this case. The patient was a man fifty years old, who gave a history of a protracted urethritis, and who was taken with symptoms of severe cystitis, and discharged large quantities of pus and mucus in the urine. Inoculations and cultures were made in various media to establish the nature of the disease. No results were obtained from the inoculation experiments. In the culture experiments a mixed form of coccus, similar to gonococcus but resembling more the diplococcus present in cerebrospinal meningitis, was found. The behavior of this coccus was entirely different from that of gonococcus in that it was rapidly destroyed in all acid media; in an alkaline medium it thrived wonderfully. The case finally resolved itself into a very obscure form of syphilis, and under the influence of mercury the urinary symptoms gradually disappeared.

Partial Excision of the Bladder and Urethra for Carcinoma.— Dr. Tuttle also reported this case of cancer of the rectum, which involved the urethra, the prostate, and possibly the wall of the bladder. The interesting features of this case were the wide extension of the disease, the relinquishment of the morphine habit after it had been so firmly established, the relief given by colotomy, and the marvellous recuperative power of the patient. The patient was in a most emaciated condition at the time of the operation, and was taking thirty-six grains of morphine a day to relieve the pain.

Second Day—May 2, 1901.

Clinical Observations on Syphilis (Clinical and Pathological Illustrations).—Dr. John A. Fordyce, of New York, read this paper, considering it under the following heads:

Gangrene of the initial lesion. He had recently observed such a case in a patient who presented no phimosis or paraphimosis, who was in good health, and who was not addicted to alcohol. During this process the induration disappeared, but it reappeared upon cessation of the process. But little was known of the etiology of the condition, aside from the conditions of the tissues, which were due to some general cause, as diabetes, alcoholism, etc. Chlorinated soda solutions he found had an exceedingly rapid and beneficial effect, probably due to the chlorine which was set free and which penetrated the tissues. The cure was facilitated by the free use of iodoform.

Lichen planus and syphilis. A certain generalized form of lichen planus might readily be mistaken for the papular or papulo-squamous syphilide. In a case reported by him there were grouped papules with circinate or gyrate outlines having a pigmented centre and surrounding areas of pigmentation. This resembled in a very striking manner a relapsing syphilide. Pruritus was very marked in lichen planus, but not present in syphilis as a rule.

Syphilis and pemphigus. He related the history of such an instance in which it was shown that a venereal history, with relapsing eruptions with pigment changes in the skin, even when combined with mucous-membrane lesions, was not necessarily a pathognomonic sign of syphilis.

Syphilis and psoriasis. A scaling papular syphilide was generally made up of small lesions which did not tend to run together in large scaling patches as in psoriasis of some weeks' duration. In the latter affection large areas of skin were often implicated by the enlargement of single lesions and the confluence of adjacent patches.

Syphilis and lepra. He related a case to illustrate the failure of the therapeutic test as an aid in diagnosing obscure eruptions. A careful examination of the patient showed a pronounced thickening and exquisite sensibility of both ulnar nerves and atrophy of the muscles of the ball of the left thumb. These conditions, together with the eruption which one would

not expect to encounter in syphilis, pointed strongly to lepra—an opinion which was confirmed by the presence of lepra bacilli in a piece of tissue excised from one of the infiltrated patches. Mercury administered into the muscles caused a disappearance of the eruption. Crocker and others had noted the rapid disappearance of leprous nodules after intramuscular injections of soluble salts of mercury.

Syphilis and lupus. The late superficial serpiginous syphilides of the skin might at times closely simulate lupus vulgaris, and while the differential diagnosis was usually not difficult, an exceptional case might come under observation which taxed our diagnostic powers to the utmost. In syphilis the inflammatory foci were scattered here and there throughout the derma, while in lupus the infiltration was continuous, looking more like a new growth than an inflammatory deposit. The connective-tissue reticulum in lupus was more pronounced, and was woven in and about the granulation tissue in a very characteristic manner. In syphilis the exudation cells were grouped about certain vessels, which early showed obliterative changes.

A Case of Prostatectomy.—Dr. James Bell, of Montreal, read a report of such a case, which presented the following points of special interest: (1) The atrophy of the left testicle fifty years before operation, and the demonstration at the time of operation that practically the whole of the prostatic enlargement, at least such as was pathological, was in the left side of the prostate gland. (2) The perfect restoration of function, which had not been usual, at least in his personal experience of prostatectomy. (3) The peculiar kind of prostatic enlargement in this case demonstrated something of the uncertainty which must always be an objection to the Bottini operation, which was now so much in vogue. Of the usual Bottini incisions made into the prostate only one could have had any effect upon the enlarged portion of the prostate.

What I Have Learned from One Hundred and Sixty-One Operations for the Relief of Senile Hypertrophy of the Prostate Gland.—Dr. Orville Horwitz, of Philadelphia, read this paper. The various operations he performed were classified as follows:

Vasectomy: Twenty-eight cases with no deaths. The results obtained led him to the following conclusions: (1) As a curative measure vasectomy was of little value, and was not to be recommended. (2) The operation appeared to be most effective when performed on patients between fifty and sixty years of age, in whom the prostatic enlargement was of the soft glandular variety. The genital organs of patients of this age were usually in a healthy condition, and the individuals usually objected to any operation that was liable to interfere with their sexual functions. (3) The operation was serviceable in those cases in which the physical condition of the patient rendered him unfit to undergo surgical procedure, in patients who would not submit to a more serious proceeding, who had to depend upon the frequent use of the catheter, or who suffered from periodic attacks of orchitis. (4) Sexual vigor was not diminished by the division of the vasa deferentia. (5) Atrophy of the testicle did not result from the operation.

Castration: Forty-four cases, two deaths. The following deductions he thought were warrantable: (1) In selected cases, bilateral castration would always hold a place in genito-urinary surgery as a means of removing the obstruction caused by prostatic hypertrophy. (2) The operation was indicated in men of advanced years, whose sexual powers were lost, the overgrowth of the prostate being glandular in character, or who had reached that period of life when the passage of a catheter became difficult and retention of urine not uncommon, or if advanced disease of the bladder and kidneys did not preclude a serious operation. (3) The primary effect of castration on the glandular prostatic hypertrophy was, first, to relieve congestion, and secondarily, to cause atrophy. (4) When the prostatic enlargement was fibrous in character, no benefit was derived from the operation, and its employment under these circumstances was not to be recommended. (5) Orchidectomy in very old subjects with extensive disease of the bladder and kidney was attended by a large mortality, and was a very serious operation.

Suprapubic cystotomy: The indications for a suprapubic cystotomy in prostatic hypertrophy might be summarized as follows: (1) When retention existed and it was found impossible to evacuate the urine by the usual methods that were employed for the purpose. (2) As a temporary palliative means in those patients who had reached the "breakdown period of catheter life," whose resisting-powers had disappeared, and who suffered from secondary involvement of the bladder and kidneys, and whose condition was such as to preclude the resort to any more serious operation, but required immediate relief from the symptoms caused by the obstructing prostate gland. (3) In feeble old men, in whom the enlargement of the prostatic growth was fibrous in character, which rendered the introduction of a catheter difficult and the passage of the Bottini cautery-knife impossible, in whom there was long-standing chronic cystitis, with probably diseased kidneys, which precluded a prostatectomy, suprapubic cystotomy might be selected as the least dangerous and most satisfactory operation which could be employed.

Prostatectomy: His conclusions he summarized as follows: (1) With the exception of ligation of the internal iliac arteries, prostatectomy was the most dangerous of all operations that had been recommended for the relief of prostatic obstruction due to hypertrophy. (2) Suprapubic prostatectomy was the safest method, especially if combined with perineal drainage. (3) The best period to select for the performance of this operation was early, before the breakdown of catheter life and serious complications had supervened. (4) An atonied or contracted bladder of long standing, associated with chronic cystitis, attended by the formation of sacs or pouches, was a contraindication for the operation. (5) A partial prostatectomy was indicated in those cases in which a valve-like lobe existed, which interfered with urination, or when there was partial hypertrophy of one of the lobes. (6) A complete prostatectomy was indicated when a hypertrophy of the three lobes had taken place, especially if the condition was associated with tumor formation, projecting well back into the bladder, or had given rise to a stenosis of the prostatic urethra. (7) Perineal prostatectomy was best suited for those cases in which the enlargement of the lateral lobes had a tendency to grow toward the rectum or obstruct the urethra. (8) In the performance of a perineal prostatectomy the semicircular incision advocated by Pyle, or the transverse cut of Nicoll, was the most satisfactory. (9) The removal of a portion of a small, hard, fibrous prostate gland by means of the perineal route was a very difficult operation. There was danger of extirpating not only the entire gland but the prostatic urethra as well.

Bottini operation: From the results obtained by the experience that he recorded in his paper he felt warranted in forming the conclusions as follows: (1) Success following the Bottini operation depended on having perfect instruments, a good battery, the necessary skill, and the employment of a perfect technique. (2) In suitable cases the Bottini operation was the safest and best for the radical cure thus far devised for the relief of prostatic hypertrophy. (3) It was often very efficacious in advanced cases of obstruction as a palliative measure, rendering catheterism easy and painless,

relieving spasm, lessening the tendency to constipation, and improving the general health. (4) It was of special service in the beginning of obstructive symptoms, due to hypertrophy of the prostate gland, and might be regarded as a means of preventing catheter life. (5) It was indicated in all forms of hypertrophy except when there was a valvular formation, or when there was an enormous growth of the three lobes, associated with tumor formation, giving rise to a pouch, both above and below the prostate gland. (6) When the bladder was hopelessly damaged, together with a general atheromatous condition of the blood-vessels, associated with polyuria, results were negative. (7) Pyelitis was not a contraindication to operation. (8) The character of the prostatic growth had no bearing on the results of the operation.

Some of the Conditions following the Bottini Operation for Prostatic Obstruction.—Dr. L. Bolton Bangs, of New York, read this paper, in which he presented some of the conditions following the operation which appeared to him to have physiological and pathological significance. He brought out three points, which he considered of importance: (1) The muscular impediment which almost immediately followed the removal of the instrument, and which was most surprising. This muscular impediment usually subsided after three or four days, when ordinary catheters could be readily introduced. In order to overcome this difficulty previous to this time he had made a series of metal catheters, patterned after the Trendelenburg searcher, and with solid tips, in order that the instrument might be rendered sterile. (2) The process of repair, as witnessed with the cystoscope, began and proceeded as under ordinary aseptic conditions. A specimen, removed from one of his patients, was then shown, which demonstrated that the grooves made had immediately relieved the mechanical obstruction. In his opinion, the spontaneous urination which followed the operation was due not only to the formation of the grooves but to contraction of the cicatrices, and to atrophy of the gland tissue. (4) The decided necessity for after-treatment was emphasized. Patients usually came with chronic catarrh of the prostate, seminal vesicles, bladder, and urethra; and the after-treatment should be continued until all foreign material had been excluded from the urine. As an explanation of the three deaths which occurred among forty-two cases operated upon, he gave "bad judgment in operating." In one case there was a parenchymatous prostatic abscess which could not have been diagnosed. In another case, death occurred in a delicate old man who insisted upon the operation being performed.

Contracture of the Neck of the Bladder.—Dr. C. H. Chetwood, of New York, read this paper (see page 767).

Officers Elected for the Ensuing Year.—*President*, Dr. W. T. Belfield, of Chicago; *Vice-President*, Dr. Paul Thorndike, of Boston; *Secretary*, Dr. James R. Hayden, of New York; *Member of Council*, Dr. William K. Otis, of New York. Next place of meeting, Atlantic City.

Nitroglycerin in the Treatment of Epilepsy.—Romano Pellegrini has found this remedy, given in 1:100 alcoholic solution, very efficacious in diminishing the frequency and the severity of the attacks. The prodromal symptoms were also notably diminished. No injurious effects were noted in patients subjected to this treatment for three months' time. The author thinks it well to alternate nitroglycerin treatment with bromide treatment, if for no other reason than to avoid the special and general disorders induced by too protracted administration of bromides.—*La Riforma Medica*, April 8, 1901.

AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, Held in Baltimore, Md., May 7th, 8th, 9th.

First Day—Morning Session.

Immediately after the executive session, the president, Dr. Roswell Park, of Buffalo, presented his address, entitled:

Some Phases of the Cancer Question (see page 761).

The Early Signs of Carcinoma of the Uterus.—Dr. Thomas S. Cullen, of Baltimore, spoke extemporaneously on this topic. He began by saying that he had little to bring forward which had not been already published, and with this preface he threw upon the screen a series of beautiful microphotographs, the most important points of which he showed to be as follows: From the three varieties of uterine epithelium as many distinct types of carcinoma developed. Positive diagnosis of carcinoma could be made in its earliest stage by curette scrapings. The presence of large, coal-black cells was pathognomonic of carcinoma.

Brief Consideration of the Cases of Cancer of the Breast Treated at the Johns Hopkins Hospital Since 1889.—Dr. W. S. Halsted, of Baltimore, presented this paper. He spoke of the unremitting efforts which he and his colleagues had for years been making to secure true pictures of the carcinomata, and of their failure to succeed in this direction. So subtle were the differences between the growths that he felt it to be wellnigh hopeless. Of three hundred and fifty cases of mammary carcinoma operated on by him, one hundred and fifty had been done in the last three years. These he would not report. Of four hundred and fifty breast tumors of every type, he had found but three sarcomata. One of these was primary, two were secondary; one from the uterus, one from the tonsil. This was considerably below the usual average given for sarcomatous infection. He spoke of the invariable malignant change which came about in the adenoma-carcinomata, and felt that the name "comedo-carcinomata," as suggested first by Bloodgood, was singularly appropriate. Dr. Halsted regretted the difficulty of establishing statistics, because of the vast differences of opinion which existed as to the carcinomatous types. In a series of elaborate charts he tabulated his cases in general as follows: (1) Those in which the cervical and axillary glands were removed at the first operation. (2) Those in which the axillary glands were removed at the first operation; the cervical at the second. (3) Those in which the cervical glands were not removed. In the first class, local recurrence occurred in eleven per cent.; in the second, in twenty per cent.; in the third, in nine per cent. The cured cases, those more than three years beyond the operation, gave the following percentages: Class 1, forty-five per cent.; class 2, thirty-three per cent.; class 3, forty-three per cent.

Late Results in Inoperable Sarcoma Treated with the Mixed Toxins.—Dr. W. B. Coley, of New York, presented these statistics. He had nothing new to add touching the preparation of the toxins. Continued observations by a number of other investigators, as well as by Dr. W. T. Bull and himself, confirmed the statement that patients affected with spindle-cell sarcoma responded best to this treatment. Nevertheless, the results were by no means discouraging in the round-cell form. It was now very definitely shown that if there was no response to the treatment at the end of three or four weeks—ample injections having been made—there was no use continuing; the case might be considered hopeless. There was practically no risk from the injections: in a series of two hundred cases he had two deaths, but these occurred before the technique was perfected. Dr. Coley advised its exhibition in hopeless cases of sarcoma only, but felt that there

might be a very broad field for his treatment as prophylactic after every case of operated sarcoma. His cures he tabulated as follows: Three to four per cent. in the round-cell sarcomata; fifty per cent. in the spindle-cell sarcomata. The melanotic forms and the lympho-sarcomata were negative. The toxins were specially indicated in cases of parotid sarcoma, because of the involvement of the seventh nerve. If given with care, the treatment could safely be continued over a period exceeding one year. In conclusion, the speaker said: (1) He advised the routine injection of the toxin in all post-operative cases. (2) It was rarely curable in carcinoma. (3) He indorsed the parasitic theory, and felt that the action of the toxins gave it substantial support.

The Influence of Mental Depression on the Development of Malignant Disease.—Dr. Joseph D. Bryant, of New York, read this very interesting paper. He traced the history of malignant disease as it had been handed down to us from the days of ancient Greece, and noted that the early observers were more prone to ascribe to physical agencies rather than to mental the development of neoplastic growth. Ambrose Paré, 1510, was probably the first to suggest a psychopathic etiological factor. Said Paré: "Anger makes cancer more fierce and raging." Others, contemporaneous with him, mentioned vigils, emotions, poignant sadness, etc. No less an authority than Sir Astley Cooper championed the psychical theory; indeed, his list of etiological factors Dr. Bryant felt to include all the mental ills that flesh was heir to. Velpeau denied it, but Virchow and Rokitanski, although qualifying it, admitted its probability. So recently as 1898 Crookshank claimed that certain cutaneous affections stood in interesting relation to mental disease. The fact that Napoleon and Grant suffered extreme mental agony might have had something to do with the cause of their deaths. After the siege of Strasbourg there was no doubt that cancer increased to an extraordinary degree. These and other factors led Dr. Bryant to investigate the relation existing in death by cancer between the mentally normal, the melancholics, and those afflicted with other forms of insanity. His conclusions in general were as follows: Of forty-four hundred and fifty-eight insane patients, there were four hundred and two female and three hundred and forty-three male melancholics. Of these, one male and four females died of cancer. This was less than one per cent. Statistics from England, Scotland, Wales, Paris, and New York showed, in over two million general deaths, cancer in 4.73 per cent. males; 8.18 per cent. females; almost double—an average of 6.42 per cent. These facts showed that melancholics suffered from cancerous infection much less frequently than the general public. Again, at Ward's Island, of the females suffering from melancholia but one-twenty-fifth of one per cent. had cancer, while in other forms of insanity it rose to one-half per cent. Dr. Bryant concluded that extreme mental depression could scarcely be considered a factor in the etiology of malignant disease.

Afternoon Session.

Cancer and Mental Depression.—Dr. J. Collins Warren, of Boston, opened the discussion. He felt that a flood of light was about to be focussed on the dark problems which had been presented in the morning papers. All over the land laboratories were springing into being for the express purpose of discovering the cause of cancer. He cordially agreed with Dr. Park that there was no doubt of the infectious nature of malignant disease. He warned the section, however, that Koch's laws should not be forgotten. In the search for the cancer parasite, how far have they been followed? Most of the experimental work had been done in inoculating animals. There was a danger that this might be a sort of grafting process; an artificial metastasis. Another important consideration was the culture of the parasite. All efforts in this line had been negative at Harvard. It was possible that when inoculation was successful it might be due to contamination. The blastomycetes had been differentiated by Plimmer's technique, and, although but little was known of them, they had, in the hands of San Felice and others, produced granular connective-tissue growths, but these might have been endothelial. We should approach the protozoon theory with great care. Dr. Warren agreed that cancer might vanish of its own accord, the degenerative changes taking place faster than the constructive. Touching Dr. Halsted's paper, he felt that prognosis was yet impossible because of the lack of statistics. These could not be obtained till a proper classification was reached. He suggested the division of cases into three classes: A, favorable; B, unfavorable; and C, palliative. In conclusion, he said that Coley's fluid afforded the only ray of hope in certain cases, and that, though it had not yet been generally successful, its use should be encouraged, particularly for the palliative treatment of post-operative sarcomata.

Dr. Thomas S. Cullen, of Baltimore, opened the discussion of Dr. Park's paper. He said that, while he had had the pleasure of seeing some of Dr. Gaylord's sections, and while admiring their beauty, still he felt there were certain limitations to their final acceptance. That Dr. Gaylord had confirmed the results of others there was no doubt; the question remained as to whether he has done more.

Dr. Roswell Park, in a few well-chosen words, said, in closing, that he had not asked for acceptance of the protozoon theory of malignant disease; there was much to follow, and full reports from Buffalo might soon be expected.

Blood Examination as an Aid to Surgical Diagnosis.—Dr. J. C. Bloodgood, of Baltimore, presented this paper. The question which he sought to solve was, In abdominal contusions complicated with intestinal rupture, were there hæmic conditions which occurred with sufficient promptness and certainty to constitute a guide for or against operation? By a series of extensive charts, he showed that as yet we knew of no such conditions. Another question he had tried to cast light upon by a study of the leucocytosis remained also unanswered: the differentiation of shock and internal hemorrhage. Of very definite import, however, was the hæmoglobin estimation prior to operation. In cases in which surgical intervention was not imperatively called for, fifty per cent. or less should contraindicate the administration of a general anæsthetic. An anæmia which exceeded this percentage constituted an undoubted danger. Should the case call for a general anæsthesia, the operation must be made as short as possible. Because of the infinite number of factors which served to vary the leucocyte count, it was difficult to speak authoritatively, but the speaker felt confident that post-operative leucocytosis was an assured fact. Leucocytosis was most important in the diagnosis of intestinal obstruction. Peritonitis showed also a constant rise—except in cases of profound depression—but it was here of little use as compared to the former condition, in which early operation would save life. In conclusion, he said that even a very great leucocytosis was in no way a pathognomonic sign. But it was at least as important as temperature, pulse, and respiration, and doubtless of more value than any single one of the three. Twenty thousand leucocytes, twenty hours after the onset of an attack, was a very sure guide to operation, no matter what the clinical symptoms might be.

The Clinical Value of Blood Examinations in Appendicitis.—Dr. J. C. Da Costa, Jr., of Philadelphia, made a report of one hundred and eighteen cases operated upon.

Blood Examinations in Relation to Surgical Diagnosis.—Dr. J. B. Blake, of Boston, read this paper on behalf of himself and his two colleagues, Drs. J. C. Hubbard and R. C. Cabot, of Boston. He first considered the leucocyte count during ether anæsthesia, and detailed a series of observations which led the authors to conclude that the effect of ether was *nil*. Post-operative leucocytosis disappeared in thirty-six hours. In simple fractures the count was rarely about 12,000. After operations for malignancy, the hæmoglobin gained, which was contrary to the usual belief. The blood in relation to typhoidal perforations afforded nothing that was reliable. The so-called "wave" was due to extraneous causes. The condition of the blood after prolonged muscular exertion approached that found in certain diseases. In the so-called Marathon races, recently held near Boston, the leucocytosis was in most cases up to 20,000; the polymorphonuclear cells increased seventy-three to ninety per cent.; the eosinophiles were absent, the lymphocytes diminished.

The Effect on the Blood of Ether Used as an Anæsthetic.—Dr. J. Chalmers Da Costa, of Philadelphia, read this paper. So much just criticism had been made of previous reports that all the patients on whom he had recently worked had been subjected to the most careful preparation, particularly purgation and diaphoresis. He found that under ether there was an increase of the red cells, a diminution of the hæmoglobin, and a reduction of the color index. The erythrocytic increase he felt to be due to a loss of the fluids of the blood. He concluded as follows: Etherization produced marked increase of hæmolysis. He set forty per cent. of hæmoglobin as the limit for operation. If below seventy per cent., there should be as little purgation as possible prior to operation.

Examination of the Blood in Relation to Surgery of Scientific Value, but too Often of No Practical Value and May Misguide the Surgeon.—Dr. John B. Deaver, of Philadelphia, read this paper. He said that blood counts had been forced too freely down the throat of the operator. They were useful within very narrow limits, but were of greater value to the surgeon than any other laboratory information. He vigorously denied that anæmia of any degree should offer a bar to operation, if such were demanded, and cited a case in which he had operated when but twenty-seven per cent. of hæmoglobin existed, the patient doing well. The heart and kidneys often contraindicated much more strongly than any anæmia, and yet we operated! Bedside observations were of greater value than any reports from a mere laboratory man.

In the discussion which then opened, Dr. B. F. Curtis, of New York, expressed very great surprise at the reports from Boston. From a long series of observations in his service at St. Luke's Hospital he had concluded that leucocytosis of a considerable degree existed during ether anæsthetization, without regard either to the operation or to the patient's condition. In three cases of intraspinal anæsthesia a progressive increase, due to the cocaine, was noted in from one to four or five hours. At St. Luke's, operative leucocytosis was a fixed factor, and often persisted so long as seriously to interfere with the use of the blood count to foretell a possible wound infection.

Second Day—Morning Session.

Bedside Work in Johns Hopkins Hospital.—The section convened in the general amphitheatre of the Johns Hopkins Hospital with a view of observing some of the special methods employed in teaching at this school.

Dr. Osler spoke first of the paramount import of bedside work. He declared the patient to be the teacher, and felt that didactic lectures, except the lecturer be extremely gifted, availed but little. But before the student could profit from bedside work he must be acquainted with the normal; hence, early in the course special attention was given to a demonstration of the physical signs in health. This was supplemented by a special course in history-taking. Without doubt, peculiar to the institution was the so-called "observation class: a modified seminar." Here the students answered such questions as "Who was Corrigan?" It virtually amounted to research work in the history of medicine. The class had no recitations save on those diseases which were rarely met with. Every case of pneumonia and of typhoid was carefully tabulated; there were special student committees to care for this; the collected data were reviewed in a monthly "round up"; and at the year's end these eight reports were woven into one. In the fourth year, for two months at a time, each student was given absolute charge of six beds under the care of the "house" physician. In closing, Dr. Osler said that just as the family practitioner learned his art by daily routine contact with the sick, so he felt that the student should begin to gather his store of knowledge by ceaseless vigil at the bedside.

The Use of the Cystoscope.—Dr. Kelly next gave a demonstration of the use of his cystoscope, calling attention to the fact, as he deftly catheterized the patient's ureters, that it was attention to the little details which made the process an easy one. The knee-chest posture; the position of the arms and of the face; the emptiness of the stomach, especially in fat women; the importance of allowing air to fill the vagina—these were some of the factors to which he drew particular attention. He spoke of the great value of cystoscopic observations in cases of pyuria, and cited a recent case in which he had been enabled to effect a cure by excision of a portion of the bladder wall which had obstinately refused to heal. He urged the use of the proctoscope in every case of supposed colitis, and cited numerous cases in substantiation of this view.

The next demonstration proved particularly interesting. Within three and one-half minutes, and under local anæsthesia, Dr. Young catheterized the ureters in a male patient whom he had not previously seen. He used Caspar's new device, one of the distinguishing features of which was that the second ureter might be catheterized without a primary removal of the instrument. Another point was that, because of its exquisite fineness of make, it effected no trauma, and hence the view was not obscured by blood. Dr. Young then demonstrated the various mechanisms by which effort had been made to reach the male ureters, and closed by saying that Caspar's new instrument seemed very nearly perfect.

Laboratory Teaching.—Dr. Welch then spoke of the scope of the laboratory teaching at the Johns Hopkins. In short, it was made as comprehensive as possible, for the knowledge the student won in this manner was a life-long possession. There was much danger of losing sight of fundamental general principles; he urged that laboratory work must be very diligently supplemented by reading, lecture, and recitation.

Demonstration Chamber of Anatomical Department of Johns Hopkins Hospital.—At noon the members were escorted to the demonstration chamber of the Anatomical Department, where Dr. Oscar H. Allis, of Philadelphia, exhibited the practical workings of his leverage appliance for the artificial fracture of bones. He had greatly improved its powers within the last year, particularly by the addition of a metal

knee cap, by which he was now able to produce many of the rarer forms of fracture.

Stellate Fracture of Acetabulum.—Of particular interest was the very successful production of a stellate fracture of the acetabulum by direct pressure from the knee. This simulated conditions in which falls from a height produced long-enduring disability; no doubt often an acetabular fracture, which was most difficult to diagnose. Not less interesting was the graphic demonstration of the wonderful elasticity of the femur. It was shown to spring fully an inch from its normal line without fracture. The third point, shown with remarkable clearness, was the relative strength, in the young adult femur, of the neck and the shaft. It was almost impossible to fracture the neck by direct downward pressure, applied between the head of the bone and the femoral condyles. When the pressure had risen to exceed a half-ton weight, the shaft snapped with the report of a pistol.

Second Day—Afternoon Session.

Pancreatitis, with Special Reference to Chronic Pancreatitis.—Mr. A. W. Mayo Robson, F.R.C.S., of Leeds, Eng., presented this paper. It was astonishing, he stated, how much had recently been written touching the surgery of the pancreas. Pancreatitis in every form had been described, but we were still sadly in the dark as to its etiology, and even more so as to its diagnosis. Until very recently pancreatitis was never differentiated from affections of the gall bladder, and even now it was difficult, even with the best methods at hand and in the presence of an open operation, to differentiate it from carcinoma of the head of the pancreas. It seemed strange that although stones had been successfully removed from the common duct for more than ten years, we were only just beginning to realize that whatever obstructed this duct might also block the pancreatic outlet. Inflammatory conditions of the pancreatic duct had been ignored, but they occurred just as in the biliary passage and presented precisely the same variety of type. The most important symptom of pancreatitis from a non-operative standpoint was an astounding and very rapid loss of weight. Operatively, of course, the well-known but equally little-understood fat necrosis could not be considered pathognomonic. For other aids to diagnosis, aside from the physical examination of the tumor, he looked to physiological chemistry. He had observed certain peculiar yellow crystals, arranged in rosettes. These could be obtained from the urine through the action of phenyl-hydrazin in jaundiced cases in which the pancreas was involved. Mr. Robson did not know what they might be, but hoped to be able by their aid to differentiate pancreatitis complicated with icterus from simple catarrhal jaundice. Just as the ducts of these two great glands were similarly involved, so the parenchyma of the pancreas suffered the same inflammatory changes as the liver. Other less valuable diagnostic points were pale-colored stools and glycosuria, but these when present occurred too late to be of note; lipuria was very rare. Etiologically, germ infection had now been shown to be the most prominent factor; but cholelithiasis, malignancy, and various of the zymotic diseases were doubtless important factors. As a rule, however, the cause was enigmatic. There were three possible paths of entry for infection: by contiguity; *via* the blood; by direct ascension of the duct, this last being by far the most frequent. The author touched most interestingly on the chemistry of fat necrosis. Great quantities of this fat split into fatty acids and glycerin; the acids united with the calcium of the blood and were deposited. This was of paramount import, for it offered an explanation of the hemorrhages in the acute form and gave substantial ground for the treatment by the chloride of calcium. Another possible cause of the hemorrhage might be looked for in the minute anatomy of the gland, which contained so very little framework. Thus, though the pancreas was the best protected organ of the body, the very slightest trauma might lead to the so-called hemorrhagic pancreatitis. This had caused him to adopt the following conclusions and classification:

(1) In certain cerebral diseases there was a general tendency to hemorrhage from the pancreas. (2) Hemorrhage might occur with or without jaundice. (3) Acute and chronic forms of pancreatitis might occur without hemorrhage.

He would therefore classify pancreatitis into the acute, subacute, and chronic, using hemorrhagic pancreatitis only as a type of the acute form. Treatment of the acute form called for exploratory operation with the same voice as acute appendicitis, incision being made in front or behind in the left costo-vertebral angle. Treatment of the subacute form was more promising. It comprised an anterior incision for the localization of the pus, which should be drained from the rear. The treatment of the chronic form was similar, but here drainage was often indirect *via* the gall bladder. Of this form, ninety per cent. recovered.

Dr. George E. Brewer, of New York, opened the discussion. He turned quickly from the clinical side to illustrate some valuable points in the surgical anatomy of the pancreas. This could best be studied from an embryological standpoint. About the fifth week of fœtal life two buds branched out: one into the anterior mesenteric fold to form the liver; one posteriorly to develop into the pancreas. This bud branched and rebranched till the characteristic acinous form was produced. Early in its development two ducts might be traced: one above, one below—the lower became the canal of Wirsung, the upper that of Santorini. To this last Dr. Brewer had given very special attention. It had been generally supposed that this canal became obliterated, but such was undoubtedly not the case; in fact, its patency probably was a very large determining etiological factor in pancreatitis. The pancreatic ducts were very variable; they might be: 1, double; 2, Santorini's duct might be patent and might empty into the bile duct; 3, there might be one, two, or three openings into the duodenum. The second point Dr. Brewer considered was the anatomical conditions which tended to determine the direction chosen by the pus of pancreatitis. This had been found to be always in the direction of the left kidney and descending colon. This was determined in part by the fact that the pancreas was retroperitoneal, in part by the rotation of the stomach which cast three layers of peritoneum posteriorly; these, being useless, fused and merged into areolar tissue. It was along this tract and into the fatty capsule of the kidney that the pancreatic pus most readily and frequently burrowed. In closing, he offered a suggestion as to the hemorrhagic etiology. Might it not be the result of a sort of auto-digestion?

Gall Stones and Acute Pancreatitis.—Dr. E. L. Opie, of Baltimore, spoke of the relation existing between gall stones and acute pancreatitis. The common bile duct in passing down to the duodenum received the pancreatic duct. From this, for some little distance, it was separated by a delicate membrane. Prior to entering the gut, they coalesced to form a sort of cloaca. The mouth was the narrowest portion of the tract, and here the stones lodged. Calculi from 3 to 5 mm. gave very different conditions from those of larger size—the small stones blocked the mouth of the papilla, leaving the orifices of the two ducts patent. There was thus established a free path for the bile direct from the liver to the pancreas. Large stones

blocked all three openings and produced very different conditions. One hundred per cent. of dogs whose pancreas was injected with bile developed a more or less grave pancreatitis.

Dr. George R. Fowler, of Brooklyn, rose to say that every case of pancreatitis should be reported. In citing three cases of his own he wished to call particular attention to an interesting symptom which he believed had as yet been overlooked. It was the sudden advent of a condition simulating grave shock which came without warning and without apparent cause. One of his patients had had three of these singular attacks, each one of which rendered her condition very grave. He operated after the third attack, established drainage, and was successful. His third patient had jaundice, which was absent in his first two, and suffered similarly from these singular collapses. He questioned whether they might not be symptomatic of the disease.

Dr. H. L. Carson, of St. Louis, cited another case, that of a very stout young woman whose important symptoms were pain, jaundice, and loss of weight. She recovered after marsupialization of the gall bladder.

Dr. W. T. Estes, of Easton, Pa., cited a case in which the diagnosis of cholelithiasis had been made, but on operating no stone was found. The head of the pancreas being much enlarged led to the diagnosis of malignancy, but complete recovery showed this case to have been one of subacute pancreatitis. His second case illustrated the tremendous fall in weight so often seen: from one hundred and sixty to ninety-five pounds.

Mr. Robson, in closing, agreed that stones were probably the great etiological factor in the interstitial form of pancreatitis. Dr. Fowler's series of relapses were of great interest and should receive attention. Dr. Opie's conclusions as to the bile being an etiological factor rested on splendid experimental ground. But must it not be infected bile? He paid graceful tribute to Dr. Brewer's work on the duct of Santorini, and felt that it doubtless, in many cases, gave path to pancreatic infection.

Treatment of Chronic Ulcer of the Stomach.—Mr. A. W. Mayo Robson, F.R.C.S., Leeds, Eng., contributed this paper. Chronic ulcer was a grave menace to human life; its treatment, therefore, was of paramount importance. Three-quarters of all cases of ulcer yielded to medical care in from four to five weeks. The remaining quarter was now cared for surgically with a mortality of but a little over five per cent. Prolonged preliminary treatment was unnecessary; antiseptic mouth washing and lavage served to clear the stomach of germs in two days if the food be aseptic. In considering the possible procedures he felt that gastro-enterostomy, which had the lowest mortality, was the best of all. He preferred the posterior operation, and with his decalcified bone bobbin it could be done in fifteen minutes. Out of one hundred and seventy-seven patients operated on one hundred and sixty-three recovered.

Gastro-Enterostomy.—Dr. J. W. Mayo, of Rochester, Minn., made gastro-enterostomy the subject of his remarks. In most cases it was distinctly the operation of choice. There were two classes of cases: (1) ulcers in the pylorus in dilated stomachs; (2) ulcers in the pylorus in small stomachs. He preferred the anterior operation, and had used Murphy's button in sixty-one cases with about one per cent. of deaths.

Dr. T. A. McGraw, of Detroit, spoke of the value of his elastic ligature in these cases. It was clean, could be quickly inserted, and would surely cut through within seventy hours.

Dr. W. G. McDonald, of Albany, had had experience with two cases of gastro-enterostomy, which, cured for the nonce, terminated within a year in carcinoma. This led him to feel that all scars should, if possible, be excised.

Dr. Rodman, of Philadelphia, agreed with the last speaker when the ulcer was situated anteriorly.

Mr. Robson, in closing, thanked the society for the hospitality and courtesy extended him.

Discussion and Remarks on Pulmonary Insufflation for the Prevention of Surgical Pneumothorax, with Demonstration of New Apparatus for Artificial Respiration.—Dr. R. Matas, of New Orleans, presented this paper. He emphasized the value of intubation, stating that by this direct method there was no danger of pumping air into the stomach, which often happened through the use of the face mask. He pointed out some of the weak points of the Fell-O'Dwyer apparatus; cited its failure in the hands of Dr. Keen in a recent pneumototomy, and exhibited an instrument which he felt to be a distinct improvement. Its importance and characteristics were: a mercurial manometer which would prevent the pressure rising above 6 mm., above which point traumatic emphysema was apt to occur; an ingenious automatic cut-off which regulated exactly the amount of air insufflated. These were the two details which he considered of the greatest importance in this branch of pneumonic work.

Third Day—Morning Session.

Resection of the Chest Wall for a Large Sarcoma; Successful Use of the Antistreptococcic Serum.—This paper was presented by Dr. W. W. Keen, of Philadelphia. The author gave the details of the operation in full, and in conclusion made special reference to the following details: (1) His method of separating the tumor from the chest wall. (2) The anterior and posterior division of the ribs prior to the opening of the pleura. (3) Fell's apparatus with mouthpiece was not satisfactory; he preferred the Bloom-Matas instrument. (4) The suture of the lung to the chest wall was followed by no untoward result and abolished post-operative pneumothorax. (5) The results of the antistreptococcic serum seemed to be quite striking. (6) Blood examination was of the utmost value, a streptococcus septicæmia having been proven by it.

A Case of Arterio-Venous Aneurism of the Right Subclavian Artery and Vein, Involving the Artery within the Scaleni. Division of the Artery between Ligatures Placed on the First and Third Divisions. Detachment of the Anastomosis (Gunshot Perforation). Lateral Suture of the Venous Orifice, after Osteoplastic Resection of the Clavicle. Recovery with Partial Loss of Hand and Forearm from Arterial Ischæmia.—Dr. R. Matas, of New Orleans, presented this paper. This was the fifteenth recorded case, but seen in the light of modern surgery it might be considered the third or fourth. The points of greatest interest in the operative technique were: (1) The failure of Rivington's traction loop to control hemorrhage. (2) The use of local anæsthesia for the first two hours of the operation. (3) Lateral phleborrhaphy of the anastomotic orifice with re-establishment of venous circulation. In conclusion, the speaker said that though there had been primary union, there occurred within a few days a sloughing of portions of the muscular tissues of the hand and forearm from arterial ischæmia. He then demonstrated his new apparatus for massive infiltration anæsthesia by which several ounces of a 1 : 3,000 or 1 : 5,000 cocaine solution were injected.

Dr. A. D. Bevan, of Chicago, in discussing this paper, spoke on the following details: (1) The possibility of proximal and distal ligation of artery without ligation of vein. (2) The need of including as little

of the artery as possible. (3) Hemorrhage from the vertebræ was to be expected. (4) Prognosis without operation in these cases was surprisingly good, particularly so in the neck. (5) Two-per-cent. gelatin injections might improve.

Dr. W. S. Halsted, of Baltimore, praised Dr. Matas' infiltration apparatus, and said how important it was to use as weak a solution as possible.

Dr. T. A. McGraw, of Detroit, stated that the question of origin of the aneurism was of great import in deciding whether or not to operate. The traumatic aneurisms were commonly stationary; those due to atheroma were progressive.

The following papers were read by title: "Subtrochanteric Osteotomy," by Dr. E. H. Bradford, of Boston. "Operative Intervention in Tumors of the Liver, with a Report of Cases," by W. G. McDonald, of Albany. "Congenital Sacrococcygeal Tumor of Large Size," by Dr. Charles A. Powers, of Denver. "Vicious Circle After Gastro-Enterostomy," by Dr. T. A. McGraw, of Detroit. "A Case of Splenectomy for Myelogenous Leukæmia," by Dr. M. H. Richardson, of Boston. "Congenital Anterior Dislocation of the Tibia, Treated by Arthrotomy," by Dr. J. B. Roberts, of Philadelphia.

Phlebitis following Abdominal Operations.—Dr. A. Vander Veer, of Albany, read this paper. Considering the trauma sustained by the great abdominal veins, it was a wonder that phlebitis was not more common. He had recently had four cases, one closely following the other; he was at a loss for any explanation of their etiology. Maybe phlebitis was of septic origin; perhaps too tight abdominal bandaging was a factor. In all his cases there was primary union of the abdominal wound; at no time was the patient's position a constrained one. It was possible that the distribution of the left abdominal veins favored phlebitis, just as in varicocele, for the disease appeared almost always on the left side.

Dr. George R. Fowler, of Brooklyn, said that the importance of this lesion varied with the frequency of its occurrence; with its percentage of mortality; with the duration of ensuing disability. In the past fifteen years he had operated on some three thousand cases, from a study of which he found that sixteen, or 0.59 per cent., developed phlebitis. Two were double and ten followed cases of appendicitis, in which marked infection was present; the rest developed in pelvic cases not septic. The clinical history of his cases was as follows: 1. Advent in from ten days to three weeks after operation. 2. Rarely ushered in by a chill. 3. Dull pains in the femoral region and in the parts just above Poupart's ligament. 4. Often an increased pulse rate without rise of temperature. 5. Palpation revealed the rope-like vein. 6. Œdema of the extremity was not marked if the patient was prone; it developed on standing and was much aggravated by walking. The prognosis as to life was good; there was more or less disability in periods ranging from three months to one year. The treatment comprised rest and counter-irritation. Dr. Fowler deprecated the excision of a vein which experience showed would ultimately undergo complete restoration of function.

Dr. W. J. Mayo, of Rochester, discussed twelve cases. Of these, three had pulmonary embolism. One patient died; he had a good, strong pulse to the last moment. In the two cases of recovery the pulse was exceedingly weak. This factor saved their lives. One-half of his cases were on the right side.

An Operation for the Radical Cure of Umbilical Hernia.—Dr. W. J. Mayo, of Rochester, read this paper. The extreme attenuation of the recti in advanced cases made muscle transplantation necessary, but under certain conditions he had found that extremely good results could be obtained by an overlapping operation, which he described in detail. The wound was closed in a transverse line rather than from side to side.

Dr. A. J. Ochsner, of Chicago, mentioned three customary methods of closing these lesions, and felt that Mayo's operation was of special use when the atrophy was not too marked.

Dr. De Forrest Willard, of Philadelphia, cited a case in which the patient weighed over five hundred pounds; he had successfully operated through eight inches of fat.

Dr. W. B. Coley, of New York, urged conservatism in very fat cases.

Dr. J. C. Warren, of Boston, spoke of the etiology of umbilical hernia. It might be due to the large fold of fat, which, tugging on the umbilical cicatrix, might predispose to rupture. He suggested the removal of this fold as prophylactic after operation.

Dr. Mayo, in closing, said that he removed as much of the omentum as was extruded.

"Excision of a Part of Three Ribs and a Portion of the Diaphragm for Sarcoma," by Dr. C. B. Porter, of Boston, was read by title.

The Prevention and Cure of Post-Operative Hernia.—Dr. James E. Moore, of Minneapolis, remarked that such herniæ were rare; indeed, it was an accident which cast a considerable slur on the care or the skill of the operating surgeon. The closure in tiers of the abdominal wound by absorbable sutures was of greater importance than anything except asepsis.

Dr. A. D. Bevan, of Chicago, agreed with the reader in the use of absorbable sutures; he had found formaldehyde catgut very satisfactory. He wished to impress on the section that we were as yet too prone to forget that there were in the abdomen typical and atypical incision lines, and that the latter should be followed as infrequently as possible. He mentioned an "autosuture": a ribbon frayed from the fibres of the transversalis aponeurosis some four inches long, which seemed to give excellent results in Bassini's inguinal hernia operation.

Fractures and Dislocations of the Spine.—Dr. S. H. Weeks, of Portland, read this paper. Although an exceedingly rare injury, he stated, dislocation of the vertebræ without injury did sometimes occur. It was almost invariably found in the lower half of the cervical region, and was usually caused by an extreme hyperflexion. It was rarely in any other direction than forward. The most prominent symptom was paralysis, which usually supervened at once; if not, its advent heralded the approach of degenerations or inflammatory exudations in the cord. The treatment of every case was immediate laminectomy, the surgeon regarding the operation purely as an exploratory one. The objections which had been raised against this course—hemorrhage, difficulty of exposing the cord, hopeless nature of injury, infection, danger from the anæsthetic—were not for a moment to be considered. Whether the dura should be opened was a question more difficult to answer in the spine than in the brain. It should usually be done, but there were certain exceptions; if opened, it should be carefully closed.

Dr. S. J. Mixter, of Boston, favored early operation, even in the cervical region. He did not sew up the dura, feeling that thus better drainage was secured.

Radical Cure of Inguinal and Femoral Hernia, with a Report of Eight Hundred Cases Operated upon from 1891–1901.—Dr. W. B. Coley, of New York, presented this paper. After dealing with generalizations, Dr. Coley spoke with special reference to inguinal hernia in the male. So perfect had the technique become that nowadays the indications for opration in the young adult were so very broad as practically to include all. He advocated a very slightly modified Bassini operation, and agreed with the gen-

tlemen from the Northwest, who so strongly advocated the use of easily absorbable suture material. The use of rubber gloves had reduced the percentage of infection from about four to one-half. In children the indications for operation were fraught with greater limitations. He rarely, if ever, advised operation in a simple case in a child under four years of age. Up to this age they could almost invariably be cured by a suitable support. From four to fourteen, he urged the faithful use of a truss for one year. If at the end of that time there was no cure, he operated. He had operated on one hundred and fifty cases of femoral hernia in women; of his technique he was unable to speak, but his results had been admirable.

Dr. J. C. Warren, of Boston, said that the modern tendency was to operate too freely on children. Trusses would often cure, up to the twenty-first year, although those cases were apt to recur. He questioned the absolute value of the absorbable suture because of his excellent results with silk.

Dr. W. S. Halsted, of Baltimore, emphasized the two factors which, at the Johns Hopkins Hospital, were considered of paramount importance: the removal from the cord of supernumerary veins, and the use of local anæsthesia. In two hundred and twenty-seven appendectomies over one thousand wire sutures had been used; in only four cases was there need of removal.

Dr. Coley, in closing, said that he did not usually advise operating on patients over sixty or under four years. Of the non-absorbable type of suture, silk was the least irritating. He emphatically objected to silver.

Pneumonotomy with Exhibition of the Patient.—Dr. W. J. Hearn, of Philadelphia, presented this case. It was one of lung abscess, which had been successfully drained by a resection of the seventh rib in the axillary line. The difficulty now presenting itself was that the opening communicated with a large bronchus.

The Use of Silver Wire and Electricity in the Treatment of Aneurisms.—Dr. Leonard Freeman reported two cases of thoracic aneurism, in one of which there was apparently a perfect cure; in the other the walls were now nearly an inch thick; it was proceeding very satisfactorily. He spoke of the use of local anæsthesia and of the need of scrupulous asepsis. He had made considerable inquiry into the disposition of the wire within the sac, and conducted the following ingenious experiment to determine this point. Feeling that the coiling of the wire in Hunter's glass bulbs scarcely simulated its behavior in the aneurismal sac, he hollowed out the interior of a large turnip and fed the wire into it. This experiment had led him to believe that the soft, malleable silver wire was much to be preferred to the hard, drawn kind recommended by Hunter. As to the amount of wire used, he believed that literally the more the better, even up to two hundred odd feet. He used a current of low amperage for a half-hour.

Dr. J. M. T. Finney, of Baltimore, opened the discussion of this paper by citing eight cases. His results were as follows: In two, there was an apparent cure; in two, death was hastened; in two, the pain was relieved; in two, the operation was as yet too recent to give report, but they promised well.

Dr. Willard, of Philadelphia, related a case which was greatly benefited: he considered the treatment a very valuable addition, and recommended a moderate amount of wire and a very weak current.

Dr. Matas, of New Orleans, had studied this question from the standpoint of abdominal aneurism. Here the problems were much more difficult of solution because of the branches, particularly the cœliac axis. In giving the indications and limitations of the operation, he drew attention to the fact that the cure of the aneurism might kill the patient by obliterating the main trunk. For success, the aneurism must be (*a*) sacculated, (*b*) unilocular; (*c*) its walls should not be too thin; (*d*) there should be no atheroma; (*e*) the lumen must be small. Unfortunately these factors could not be discovered during life.

Movable Kidney: its Cause and Treatment.—Dr. M. L. Harris, of Chicago, read this paper. From a series of very elaborate measurements in women, men, and children, Dr. Harris demonstrated that the location of the kidney bore a definite relation to the body form. Dividing the abdomen into three zones, he found a very constant relation between prolapsed kidneys and those body forms in which the nephric zone was abnormally small. He felt that the etiological factors commonly given bore but little if any causal relation to movable kidney. The object of the operation should be not to lift the kidney from the lower zone into the middle, which was too small for it, and there sew it fast, but rather to obliterate the excess of space in the lower zone, and, without anchoring it absolutely, limit its nefarious excursions.

Two Cases of Abdominal Contusions.—(1) Fracture of spleen—splenectomy—recovery. (2) Fracture of kidney—nephrectomy—recovery. Dr. S. J. Mixter, of Boston, cited these two cases. The important considerations were that early operations were indicated in these grave, crushing injuries, and that the conservative treatment was the ablation of the injured organ rather than any attempt at its repair.

Nephrolithotomy on Both Kidneys.—Dr. S. J. Mixter, of Boston, read this paper. The distinctivee fature consisted in a demonstration by the *x*-rays of the enormous quantity of stones which might for years reside in both kidneys without causing either suppuration or serious interference with function.

New Method of Closing Defect after Thorough Removal of Breast.—Dr. S. J. Mixter, of Boston, presented this paper. He dwelt only on the technique; by an ingenously devised incision he slid the normal breast to the mid-line, thus closing the operation site, without tension, with one continuous line of suture.

Dr. J. C. Warren, of Boston, felt that the æsthetic side of this operation must be considered. While admirable in many respects, Dr. Mixter's operation would tend to make the woman pigeon-breasted.

Dr. W. H. Carmalt, of New Haven, had had excellent results from the use of this technique, and felt that Dr. Warren's criticism did not invalidate its utility.

The following officers were elected for the ensuing year: *President*, Dr. De Forest Willard; *First Vice-President*, Dr. Robert Abbe; *Second Vice-President*, Dr. R. Matas; *Treasurer*, Dr. George R. Fowler; *Secretary*, Dr. Dudley P. Allen; *Recorder*, Dr. Richard H. Harte.

Meeting-place, Albany, N. Y., May 20, 1902.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 11, 1901:

	Cases.	Deaths.
Tuberculosis	254	156
Typhoid fever	29	10
Scarlet fever	676	49
Measles	315	8
Diphtheria and croup	314	52
Smallpox	107	19
Chickenpox	74	0

To Arrest a Cold, rinse the nose thoroughly with a weak solution of potassium permanganate.—Nassauer.

ORCHITIS AND EPIDIDYMITIS IN TYPHOID FEVER.*

By FRANCIS P. KINNICUTT, M.D.,

NEW YORK,

PROFESSOR OF CLINICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT OF COLUMBIA UNIVERSITY.

It is not intended in the present paper to do more than to record the clinical histories of two cases illustrating a rare complication or sequel of typhoid fever.

Orchitis or epididymitis occurring as a complication or sequel of typhoid fever was first alluded to by Velpeau[1] in 1844. An incomplete case was reported by Chedevergne in 1868,[2] and the first complete case by Hanot[3] in 1873. Westcott[4] in 1898 had collected thirty-two cases, and in the same year Eshner,[5] after a thorough search through the literature, was able to find only forty-four cases, which have been analyzed by him in an interesting paper. The rarity of the lesion is also indicated by the fact that in Pierre Do's Thèse de Lyon,[6] 1899–1900, on epididymo-orchitis of typhoidal origin, the statistics of complications occurring in 14,738 cases of typhoid fever drawn from French and German sources show no record of any instance of epididymitis or orchitis. In Osler's[7] series of eight hundred and twenty-nine cases of typhoid fever published in 1900, orchitis or epididymitis was observed only in two instances, both unattended with suppuration; and in the eight hundred and eighty-nine cases treated in the Presbyterian Hospital from 1892 to 1901 in my colleagues' services and my own, this lesion was noted only in the two instances related in the present paper.

It is probable that the frequency of this complication is greater than the statistics indicate. Aside from cases which presumably have not been reported, the fact that in the forty-four cases collected by Eshner[5] five occurred after the second week of convalescence, one of these as late as the ninth week, suggests the presumption that cases occur in which the true origin of the orchitis is not suspected.

The two cases which form the subject of the present paper occurred nearly simultaneously in my service in the Presbyterian Hospital, during the past winter; and the interesting opportunity was afforded of studying and comparing their different clinical histories.

Case I.—D. S——, male, age twenty-four years, was admitted to the Presbyterian Hospital in my service on January 30, 1901, apparently on the seventh day of his illness. The previous diagnosis of typhoid fever was confirmed after admission. There were enlargement of the spleen, and a characteristic eruption; the leucocyte count was 8,000 on the day of admission. The Widal test gave a positive result on the tenth day of the disease. The infection was of a moderately mild type: the maximum temperature did not exceed 104.5°; there was only slight mental disturbance. The treatment was the customary one, viz., the cold bath. The illness was an uneventful one, without complications. The morning temperature was normal on the twenty-first day of the illness, and both morning and evening temperatures were normal on the twenty-third day. The leucocyte range was unusual both during the course of the fever and later in convalescence, in the presence of a sequential lesion. On admission the leucocyte count was 8,000 and remained at about this point until the fifteenth day of the patient's illness, when it rose to 14,000. There was then little variation until the eighteenth day, when the count was 11,000, and from this date it gradually but continuously receded to 7,000. The increase in the number of leucocytes occurred without any appreciable cause, and the decrease continued in the presence of a lesion during convalescence.

The urine was examined every other day during the patient's stay in hospital. A faint trace of albumin was present from admission until the 21st of February, the twenty-ninth day from the beginning of the illness, but at no time were casts found. The catheter was not used during the patient's stay in hospital, and there was at no time any urethral discharge. There was no history or evidence of gonorrhœal infection in the past.

On the fifth day of normal morning and evening temperatures, the patient complained of slight pain in the right groin, and on examination what appeared to be a swollen gland could be detected. The temperature rose to 101°. On the following day, the apparent swollen gland was found to be the cord, enlarged, hard, and sensitive, in the inguinal canal. The following day the swelling had reached the external ring, and in the course of the succeeding twenty-four hours the morbid process had extended to the epididymis and testicle. The cord could now be palpated, swollen, hard, and sensitive, throughout the inguinal canal into the scrotum to the epididymis. The epididymis and the testis proper became markedly swollen and very sensitive. There was no effusion into the tunica vaginalis.

Almost simultaneously with the appearance of the swelling of the cord, pain and tenderness were developed in the upper portion of the long saphenous vein. The phlebitis gradually extended throughout the course of this vein to the lower part of the leg, and was attended with moderate swelling of the leg and thigh.

The swelling and tenderness of the cord and testicle gradually subsided, and on discharge from hospital, on the sixteenth day after the first appearance of the symptoms, the only evidence of the testicular lesion consisted of a trifling induration and sensitiveness of the epididymis. The temperature remained slightly above normal until the eleventh day after the development of the orchitis and phlebitis of the saphenous vein. There were still sensitiveness along the course of the saphenous vein and moderate swelling of the leg and thigh on the patient's discharge.

The study of other cases of orchitis occurring in the convalescence of typhoid fever indicates that the lesion is, as a rule, attended with little constitutional disturbance. The persistence of the fever in the present case was attributed to the concurrent phlebitis of the saphe-

* Read at meeting of the Association of American Physicians, Washington, May 1, 1901.

nous vein. Bacterial examination of the urine was not made.

On examination of the patient on April 20th, ten weeks after discharge from hospital, all physical signs of a lesion of cord, epididymis, and testicle were absent. The leg and thigh were still slightly swollen, but tenderness on palpation along the course of the saphenous vein had disappeared. The patient complained, however, of pain along the course of the vein and of tenderness in the testicle after much standing or walking.

Case II.—A. S——, male, age thirty-four years, was admitted to the Presbyterian Hospital, in my service, December 18, 1900, apparently on the fourteenth day of his illness. On admission, the Widal test gave a positive result; the spleen was palpable; there was a copious and characteristic typhoid eruption; the leucocyte count was 8,000; there was no history of venereal disease in the past; there was no urethral discharge, and a catheter was not used during the patient's illness.

The infection was of a mild type. The maximum temperature was 104°. There was no mental disturbance, and a normal morning temperature was reached on the tenth day after admission, apparently on the twenty-fourth day of the illness. Both morning and evening temperatures were normal on January 2d, the thirtieth day of illness.

The urine on admission contained a small amount of albumin and a few hyaline and granular casts; and similar conditions were noted until January 10th. On December 31st, a very considerable number of leucocytes were found in the urine, and a slight degree of pyuria continued to be present until January 10th. From this date, examinations of the urine were negative until the discharge of the patient from hospital, January 30th.

With the development of the pyuria, there was a rise of temperature, maximum 102°, which persisted during its continuance. From January 10th there were normal morning and evening temperatures until January 14th, when the evening temperature rose to 101°. Two days later the temperature was normal and remained so until the patient's discharge from hospital.

Coincident with the last rise of temperature, the patient complained of pain in the right testicle. On the following day the scrotum was reddened; the epididymis and testis proper were both involved, being greatly swollen and acutely sensitive, the epididymis being especially affected. The cord apparently was not implicated. The inflammatory symptoms rather rapidly subsided, and on January 30th, the date of discharge, the only remaining sign of the lesion was a slight tenderness and induration of the epididymis. The urine was not examined for typhoid bacilli.

The patient was readmitted on February 26th. A week after discharge from hospital there was a recurrence of pain in the right testicle, which again became swollen and sensitive. These conditions persisted until his readmission.

On admission, the temperature was normal; the right half of the scrotum was reddened and greatly swollen. On palpation, both the epididymis and testicle were found to be swollen, hard, and exquisitely sensitive. At one point over the testis proper, fluctuation was appreciable; there was no effusion into the tunica vaginalis. The cord, double its normal size and very hard to the feel, could be traced from the epididymis to the external ring and throughout the inguinal canal.

On examination by Dr. Tilden Brown, the seminal vesicles were found to be insensitive and apparently of normal size. The prostate was enlarged but not sensitive on palpation. The ordinary urinary examination was entirely negative, and bacteriological examination of the urine failed to reveal Eberth's bacillus.

Aspiration at the point of fluctuation was made and a small amount of pus was obtained. The bacteriological examination of the pus by Dr. Tuttle, the assistant pathologist of the hospital, demonstrated the presence of Eberth's bacillus in pure culture.

The swelling and sensitiveness of the testicle, epididymis, and cord have only very slowly subsided. The cord, two months after the readmission of the patient, can be palpated as far as the internal ring; it is hard, nearly double the size of the cord of the opposite side, and slightly sensitive. Both the testicle and epididymis are still very hard to the feel, and a small sinus leads to the body of the testis, through which minute shreds of necrotic tissue are occasionally extruded.

In the fifty-three[8] cases of testicular inflammation occurring in the course or during the convalescence of typhoid fever, which comprise the literature of the subject, suppuration developed in thirteen. Bacteriological examination demonstrated the presence of Eberth's bacillus in pure culture in the pus from six of the cases.[9] In a single instance,[10] pyogenic cocci alone were found. The remaining six cases[11] were reported prior to or about the date of Eberth's discovery of the specific bacillus of typhoid fever.

In one non-suppurative case,[12] Eberth's bacillus was found in pure culture in the sero-sanguinolent fluid obtained from an aseptic puncture of the testicle.

In view of the bacteriological findings, the usual origin of orchitic lesions in typhoid fever cannot be doubted. Apparently only exceptionally is the infection due to other micro-organisms than Eberth's bacillus. It remains to consider the probable channels of infection.

It is probable that the bacilli reach the testicle both by the blood stream and from the urethra through the intermediary of the vas deferens. That Eberth's bacillus in great numbers is found in the urine in a large percentage of cases of typhoid fever is now well known.

In Case I. of those whose clinical histories have been given, the pathological process evidently originated in the cord within the inguinal canal or at a point above it, and thence gradually extended to the epididymis and the testicle.

It will be recalled that it was possible to trace the gradual progress of the lesion, the epididymis being affected only forty-eight hours after the cord was palpable (swollen, hard, and sensitive) in the canal. The prior implication of the cord suggests an original infection either of the vas or of the spermatic veins, producing a phlebitis with thrombotic formation and a secondary implication of the vas by contiguity. The nearly simultaneous development of a phlebitis of the internal saphenous vein suggests the possibility of a similar lesion of the spermatic veins. It will be recalled that the internal saphenous vein receives the external pudic, which crosses the spermatic cord.

In Case II. the infection affected the epididymis and testicle to the exclusion of the cord in the first attack. It was acutely involved in the recrudescence.

It may be of interest to analyze briefly Eshner's forty-four cases[8] and the nine additional ones[8] which I am able to add, of orchitis and epididymitis occurring in the course or during the convalescence of typhoid fever, comprising all cases found in the literature of the subject which give sufficient detail to be of value.

Sixteen cases developed during the course of the fever. Of these, one occurred during the second week, six during the third week, two during the fourth week, one during the fifth week, one during the sixth week, two during the seventh week, two "at defervescence," one at a time not definitely stated.

Thirty-five cases developed during convalescence. Of these, eleven developed during the first week, seven during the second week, three during the third week, one during the fourth week, one during the fifth week, one during the sixth week, eleven at a time not definitely stated. In two cases the date of development is not given.

In two cases the inflammation affected both sides, in forty-five it was unilateral, and in six cases no statement is made of its localization.

Of the unilateral cases, twenty-two were on the right side, twenty-one on the left, and in the remaining two it is not stated on which side.

The epididymis only was involved in seven cases; the testicle only, in sixteen cases; both epididymis and testicle, in twenty-six cases; and in the remaining four, a distinction is not made between the testis proper and the epididymis.

There was effusion into the tunica vaginalis in nine cases; in ten, it is noted that such effusion was absent; and in thirty-four no statement is made on this point.

Suppuration occurred in thirteen cases, partial necrosis in five cases, complete necrosis in two cases, and death in two cases, but without apparent relation to the complication.

Recovery with residual nodules in the epididymis is noted in seventeen cases; the subsequent histories of these cases would be of interest.

The bacteriological examinations of the pus in the suppurating cases have been given earlier in this paper.

A study of these cases justifies the following conclusions:

1. Epididymitis or orchitis occurring in the course or during the convalescence of typhoid fever is a rare lesion and is of typhoidal origin.

2. Only very exceptionally is it due to secondary microbic infection.

3. It develops at a late period in the disease or during convalescence.

4. The lesion, although as a rule unilateral, may be bilateral; and involves either the epididymis or testicle or both, and not infrequently the cord.

5. Effusion into the tunica vaginalis is rare.

6. Termination most often is by resolution.

7. Suppuration occurs in twenty-five per cent. of all cases.

8. Localized necrosis and extrusion of testicular tissue is not uncommon.

9. Exceptionally there is destruction of the entire testicular structures.

10. Atrophy of the testicle occurs, but is a rare sequence.

11. The lesion gives rise to little constitutional disturbance.

12. Death as a direct result of the lesion has not been noted.

THE OPERATIVE TREATMENT OF UMBILICAL HERNIA IN ADULTS.*

By JOSEPH A. BLAKE, M.D.,

NEW YORK.

It has seemed to the writer that the advances in the treatment of umbilical hernia have been sufficient to warrant the presentation of the subject to a general meeting such as this.

Although the chief subject of this contribution is the operative treatment of the more severe forms of umbilical hernia, yet at the same time it is well to review what can be accomplished in the less advanced cases, for, if more early operations were done, there would be less hesitancy in invoking operative interference; also, since the cases differ so in the anatomical and pathological features they present, it will be necessary to enter into a brief consideration of their etiology, course, and pathology.

The usual classification divides umbilical hernia into three groups: 1. Congenital hernia of the cord. 2. Infantile umbilical hernia. 3. Adult umbilical hernia.

The first of these had perhaps better be termed "hernia into the cavity of the cord," inasmuch as in these cases no umbilicus is present, the cavity being the persistence of a well-recognized early embryonic condition.

The second class occurs in infancy and childhood. Berger[14] places the dividing line between it and adult umbilical hernia at fifteen years. This form is due to a weakness in the umbilical cicatrix, and is usually quite amenable to treatment by a simple pad or truss. According to Berger,[14] it forms 22.42 per cent. of all herniæ occuring in male children under fifteen years, and 65.34 per cent. of all herniæ in female children at the same period.

The third class, adult umbilical hernia, according to the same author, forms 2.15 per cent. of all herniæ in males over fifteen years and 22.16 per cent. of all herniæ in females over fifteen years; the preponderance in females of three to one under fifteen years, being changed to over ten to one over fifteen years of age. This marked relative increase in women must be attributed chiefly to pregnancy and parturition, and, furthermore, we find that at about the age of forty years, according to the same statistics, umbilical herniæ are more common in women than any other form.

In the majority of these cases in women, especially when attributable to multiple pregnancies, we also find other conditions present, namely, separation of the recti muscles and often loose or pendulous abdominal walls.

The stretching of the abdominal wall is apparently the precursor and cause of the hernia at the umbilicus.

The desirability of subdividing the class of adult umbilical herniæ at once suggests itself, namely, into those without and those with separation of the recti muscles. This is especially desirable from the operative standpoint, inasmuch as the conditions to be met and overcome differ widely.

Adult umbilical herniæ without separation of the recti present practically the same anatomical features as do infantile umbilical herniæ. The sac is gener-

* Read before the Medical Association of the Greater City of New York, January 14, 1901.

ally comparatively small, and if operative treatment is indicated, the radical cure may be readily accomplished by uniting the borders of the recti by the methods now usually employed for closing median cœliotomy wounds.

The other cases, however, with separation of the recti muscles, present a much more difficult problem, and it is to the consideration of these cases that your attention is especially called.

In the first place, it is well to review briefly the causes and development of the conditions found.

The recti muscles under normal conditions undoubtedly do much to support the linea alba and protect it against the strain of the lateral abdominal muscles. The splitting, as it were, of the insertion of these muscles to include the recti is apparently a provision of nature in this direction. The recti may be likened to bowstrings, which, by their tension, resist lateral deviation.

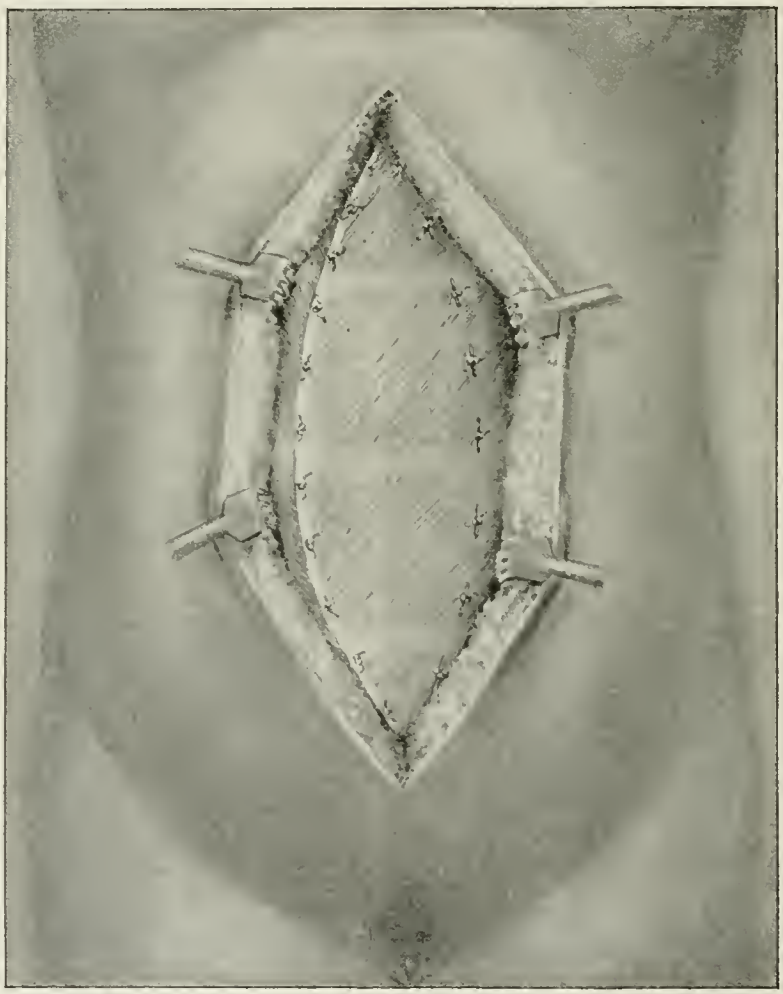

Fig. 1.

Any cause acting to diminish the contractile power of these muscles, or to prevent their acting in straight lines, must be a factor in producing lateral stretching of the linea alba and their consequent separation. Lack of muscular tone and fat diminish their contractile power, and the presence of abdominal tumors, such as the pregnant uterus, not only weaken them by stretching, but vitiate their line of contraction, so that, instead of protecting the linea alba, they actually help to stretch it. Having commenced to stretch, the linea alba naturally tends to increase in width, especially if additonal pregnancies supervene.

The recti being fixed at their extremities, the linea alba becomes elliptical in shape, the greatest separation of the recti being at about their middles; hence, the maximum stretching of the tissues is at the region of the umbilicus, and its potential weakness usually determines the site of hernia, although hernial protrusions may take place above or below it, usually below it. Such herniæ should be placed in the same category as umbilical herniæ of this class, and present the same conditions in regard to operative treatment.

The recti may be separated for a considerable distance. Sapiejko[12] operated successfully upon a case in which the separation was 15 cm.

The stretching process is not confined to the linea alba, but the sheaths of the recti also participate in the process; and in extreme cases the muscles may become a flattened sheet of muscular fibres, so that it is difficult in operations to recognize their mesal borders.

In advanced cases the abdominal walls are loose and are often pendulous, and do not afford adequate support for the viscera. The patients not only suffer from the hernia symptoms proper, but also those of enteroptosis. At the same time the flaccid abdomen precludes the employment of an efficient truss.

Small umbilical herniæ do not give, as a rule, many symptoms, but they tend to increase in size, especially if the causes which produced them are still operative.

The symptoms in the larger herniæ may be classified into those arising from the size of the hernia and those due to complications. The size of the hernia is a cause of inconvenience. It may ulcerate on account of the poor nutrition of its coverings, and it may produce intestinal and gastric symptoms from the inclusion of large amounts of viscera or from dragging on account of adhesions, etc. Pain is often a marked and serious symptom. The total effect is not infrequently almost if not complete invalidism.

The chief complications are adhesions, causing irreducibility, obstruction, and strangulation. In many of these cases a history of intermittent obstructions may be elicited which have not persisted, but which have been a serious menace to the life of the individual. In regard to strangulation, it is generally stated that it is less common in umbilical than in femoral or inguinal herniæ. According to Berger,[14] in every one hundred cases of strangulation there are fifty inguinal, forty-four femoral, and six umbilical herniæ.

Umbilical herniæ form 7.45 per cent. of all herniæ occurring after fifteen years of age; thus there is apparently a slight difference in their favor as regards strangulation; but if we eliminate those occurring in the male, and the small cases, in which cases strangulation is infrequent, and should confine ourselves to the larger cases, we would probably find that it is comparatively frequent. It has been found impossible to obtain statistics upon this point.

Irreducibility from omental adhesions to the sac is exceedingly common and seldom absent in the larger herniæ. Its presence, of course, precludes the employment of a truss and increases the chances of strangulation, besides often being the cause of other symptoms.

In regard to the prognosis without intervention, we may say that in the male, and in some cases in women, in which it is possible to employ an effective truss, the prognosis seems perfectly good, and operation is not indicated. In women, as a rule, however, the prognosis is not so happy. There is a marked tendency to increase in size, especially in herniæ occurring during the child-bearing period. With the increase in size come the distressing symptoms and complications and the ever-lessening chance of a complete radical cure. If strangulation occur, the prognosis is more grave than in either inguinal or femoral hernia (Bull and Coley[10]).

According to Gibson,[2] in gangrenous hernia the mortality of umbilical hernia is sixty-seven per cent., of inguinal hernia twenty-six per cent., and of femoral hernia thirty-seven per cent.

Operative Treatment.—In regard to operative treatment it must be confessed that the results have been disappointing, so much so as to warrant the general dictum that, unless the symptoms absolutely indicate interference, operation is not indicated. This is especially true in regard to operations upon the larger herniæ; but is not in the small and early cases, as the statistics show.

Statistics in regard to the results obtained in umbilical herniæ are of little value from either point of view. On the one hand, many cases reported are isolated, as it were, and we do not know how many failures are behind each successful one. On the other hand, many operations have been done by defective methods, and have invited recurrence. According to Berger,[14] relapses occur in about thirty per cent. of operations on large herniæ, fifteen per cent. to twenty per cent. on those of moderate size, and practically none on those of small size. In cases with suppuration sixty per cent. relapsed. These figures are probably too good. In thirty-four cases operated upon for large hernia in the Hospital for the Ruptured and Crippled in this city, twenty-one were traced with twelve relapses, *i.e.*, in the neighborhood of fifty per cent. These operations were by skilled operators, and the results are more probably nearer the actual facts. There is naturally no comparison between the results obtained in small and large herniæ, inasmuch as the small herniæ, as before stated, present very little greater difficulties than are encountered in closing an ordinary cœliotomy wound.

The mortality, according to Bull and Coley,[10] in irreducible cases, is not far from five per cent., increasing or diminishing with the size of the sac and the extent of the adhesions. In strangulated herniæ, the mortality is in the neighborhood of sixty per cent. In small herniæ the mortality should be *nil;* another strong argument for operation before increase of size and advent of complications. Rather than wait for indications, we should operate in all cases in which there is a probability of increase in size.

Before considering the operative methods it is well to review the conditions which have to be met and overcome in large umbilical herniæ with separation of the recti muscles.

First: There is present an amount of separation of the recti muscles, which is as great, if not greater than the width of the neck of the sac. The absolute futility of approximating the border of the hernial opening and leaving the remaining separation of the muscles untreated is evident, inasmuch as the line of suture will have to bear almost the entire strain of the lateral abdominal muscles. Disregard of this fact alone is responsible for many failures.

Secondly: The lateral stretching and thinning of the recti and their sheaths render it difficult to find sufficient muscle fibres for approximation.

Thirdly: Tension is one of the chief difficulties encountered in approximating the borders of the muscles or their aponeuroses after excising the margins of the ring. This could possibly be overcome to a certain extent in obese patients if sufficient time before operation were to be had to reduce the amount of intra-abdominal fat.

Other conditions, such as extensive adhesions, large masses of irreducible omentum, and conditions of general vitality, are difficulties which are common to all operative procedures, and have no bearing upon any particular method.

Operative Methods:. The essential parts of the radical cure in the repair of the abdominal wall and the description of methods will be confined to it alone.

It will be of interest to review some of the methods which have been employed, not alone from their bearing upon the subject in hand, but also from the fact that they have been more recently exploited as presumably new in the closure of ordinary cœliotomy wounds. More space, however, will be given to a method which is comparatively recent, and which was supposed by the writer to be new when first employed by him, but was later found to have been already advanced as a new method by Sapiejko[12] in France, and by Piccoli[6] in Germany, who published their articles within a month of one another.

The different methods may be divided roughly into five categories:

1. Lineal approximation of margins of fascia or fascia and muscle.

By far the greater number of operations fall within this group.

The first operations were done with the through-and-through suture of all layers after removal of the sac.

To Condamin[4] the credit is given of excising the ring and suture of peritoneum, aponeurosis, and skin in separate layers. Socin devised the method of splitting the sheaths of the recti. This was perfected by Sanger,[7] who published his memoir in 1890. He sutured the peritoneum, the dorsal sheath with part of the rectus, the ventral sheath with the remainder of the rectus, and the skin, in separate layers. Gersuny[6] sutured the margins of the muscles themselves together and the skin so that the lines did not coincide.

The objections to the methods in this category are the difficulty in overcoming the separation of the recti, in accurate approximation of the layers, the superimposition of the suture lines, and the chances for the inclusion of properitoneal fat in the lines of apposition of the muscular and aponeurotic tissues, thus preventing accurate union and predisposing to relapse. Tension is also overcome in some cases with great difficulty, and numerous sutures have to be introduced.

The method by splitting the sheaths of the recti and union in several layers is the best, and, moreover is probably the most applicable of these operations to the cure of small herniæ.

2. Interlacing of fasciculi of the inner portions of the recti after splitting their sheaths was devised by Dauriac.[13] This method brings up the question of the vitality of transplanted muscle fibre. It is difficult to see its advantages over the method of simple approximation of the bare muscle.

3. In order to overcome the separation of the recti muscles, Lucas-Championnière[9] devised a method of involuting the abdominal wall in the middle line, by a method resembling the Czerny-Lembert method of intestinal suture; thus approximating the ventral surfaces of the recti sheaths over a greater or less area, depending upon the amount of relaxation of the abdominal walls.

4. Flap operation. By this method the hiatus in the abdominal wall after the removal of the sac is closed by reflecting flaps from the sheaths of the recti

muscles. No attempt is made to approximate the muscles. The method depends upon the intimate fusion which exists between the ventral and dorsal sheaths of the rectus at its mesal border, thereby allowing the dorsal sheath to be pieced out, as it were, by reflecting a flap of the ventral sheath with its attached border at the mesal border of the rectus, *i.e.*, in continuity with the dorsal sheath.

The credit of first proposing this method seems to belong to C. P. Noble,[1] of Philadelphia, who used it in 1896 in closing a ventral hernia. It was also used by two Russian surgeons at about the same time (Diakonoff and Starkoff [16]).

The flap may be taken from one side and united to the margin of one of the sheaths of the opposite rectus (Heinrich [8]), or a flap may be taken from each rectus and be united to one another either by apposition of the edges or by lapping (Hagen,[3] Ferguson[11]).

The chief objections to this method are, first, that the flap of sheath, when removed from the muscle, is deprived of its nutrition, and is liable to necrose, or at least atrophy; second, that the method cannot be used in the lower part of the abdomen, where the dorsal sheath is deficient; and third, that the removal of the flap weakens the insertion of the lateral abdominal muscles. However, several very good results by this method have been reported.

5. Lapping the abdominal wall. This method is particularly applicable to the cases in which there is stretching of the linea alba, with separation of the recti. It consists of the division of the linea alba above and below the sac in the median line for the necessary distance, with or without excision of the ring and a portion of the linea alba. The entire wall on one side is then lapped in front of the other, and there sutured, so that the ventral surface of one side is in contact with the dorsal surface of the other.

This method first suggested itself to the writer in an operation for umbilical hernia in this past month of September. Two additional cases since then have been operated upon by the same method, with modifications to suit the particular conditions found. Inasmuch as these cases illustrate very well the possibilities of the operation, the details as far as necessary will be given.

The first patient was a multipara of thirty-eight years, who first noticed bulging at the navel two years before, immediately following a miscarriage. On account of the rapid increase in size of the hernia in the preceding six months, the occurrence of pain, and the fact that it was irreducible, operation was advised. The following conditions were present: The abdomen was large, the walls were rather lax, the subcutaneous fat was abundant; the hernial sac was the size of an orange, the omentum adherent, the ring being one and one-quarter inches in diameter. Diastasis of the recti was present for a distance of a little over one and one-half inches, and for some distance above and below the hernia. The fact being recognized that if attempts were made to unite the recti muscles the linea alba would have to be excised for a considerable distance above and below the sac, and that approximation would then be very difficult on account of tension, only a portion of the sac was excised, and the linea alba with the peritoneum divided for two inches above and below the ring in the median line. The peritoneum was then separated for about two inches on either side of the wound, the separation being carried farther to the left than the right, and sutured in the median line. The ventral surface of the right half of the stretched linea alba and adjoining rectus was then carefully cleaned of fat. Mattress sutures were then passed through the free margin of the right half of the linea alba and corresponding portion of sac in a dorso-ventral direction, and then in the same direction through the left rectus muscle and its sheaths, and tied on the ventral surface of the sheath. In this way the ventral surface of the right rectus sheath and linea alba was applied to the dorsal surface of the left. The free edge of the left abdominal wall was then tacked to the ventral sheath of the right rectus. In this way a total lap of one inch and a half was easily obtained without undue tension, thus giving a lap of the muscles of three-quarters of an inch. The greatest width of the lapping was made at the hernial site, tapering away to nothing at the extremities of the incision; thus the lines of suture formed an elliptical figure (Fig. 1). Healing occurred per primam, and the result so far is perfectly good. By leaving the margin of the sac, a handle, as it were, is provided in applying the sutures; but it is unnecessary if the abdominal walls are lax.

The second case operated upon illustrates a modification in regard to the treatment of the peritoneum. The patient was a woman seventy-nine years of age, who had had her hernia for twenty years. Five years previous to operation it had become strangulated, but was successfully reduced by taxis. The operation was done on account of strangulation, which had existed eleven hours. The patient was very large and obese. The same operation as described was performed, with the exception that in order to save time no separate suture of the peritoneum was made, but instead the peritoneum was scarified and scraped on the dorsal surface of the left rectus, where the ventral surface of the right rectus was applied. The peritoneum is intimately connected with the dorsal sheath in this region, there being little or no intervening fat, so that firm union can be obtained. The same measure has been recommended by Piccoli.[5] The patient made an uneventful recovery; there was no shock, and the wound healed per primam. The abdominal wall is strong. The result was especially pleasing, since the operation was done in a small, dark room, with very few conveniences.

The third case was operated upon on the 24th of last November. It illustrates the application of the method to another condition, namely, hernia through the linea alba below the umbilicus, with marked separation of the recti and pendulous abdomen. The patient was a multipara of forty-three years. Her condition was a source of pain, discomfort, and digestive disturbances. The hernial protrusion proper reached from just below the umbilicus to within two inches of the pubes. The recti were separated for a distance of three inches at the umbilicus, and were very wide, being thinned out to a mere sheet of muscle fibre. The technique was much the same as in the first operation—*i.e.*, separate suture of peritoneum, lapping of recti, and suture of skin—except that the wound was much more extensive, being twelve inches in length, and the lapping greater. The entire linea alba and sac were trimmed away, except for a border of a little over an inch left on the left rectus, and the muscles themselves lapped for a distance of three inches. The skin and subcutaneous fat, which was two inches in thickness, were removed in an ellipse, which was twelve inches long and eight inches in width.

The patient made a good recovery, the wound healing per primam. There was rather excessive vomiting for the first thirty-six hours, which caused some worry in regard to the holding of the stitches, but no bad results followed.

In all three cases the suture material used was plain catgut for the peritoneum, No. 2 chromicized gut for the aponeurosis and muscles, and silkworm gut and silk for the skin. Two points in the technique should be emphasized, namely, the absolute cleansing of fat from the rectus sheath, which is to be applied to the back of the opposite rectus, and the insertion of the

mattress sutures, so that they will be in the course of the muscle fibres and not strangulate them. It has been found more convenient to have the mattress sutures threaded on two needles. The sutures include about one-third of an inch of the tissues, and are placed about five-eighths of an inch apart.

The cases operated on by the writer are too recent to deduce the ultimate results, but demonstrate the success of the immediate results.

The fact that such broad surfaces are united almost negatives the chances of future separation; also experiments in regard to this point have been made by Piccoli on dogs, and he has found that, from two weeks up to four months after the operation, the union was firm and intimate, even under the microscope. Piccoli's article was published in January, 1900. His results have been satisfactory. His method is much the same as that employed by the writer, the chief difference being in the use of silk and in the insertion and tying of the sutures.

Still better proof of the efficacy of the method is afforded by the results of Sapiejko,[12] who employed the same lapping, but used continuous sutures. He operated in December, 1898, on a woman aged thirty-four years, four months pregnant. In this case there was diastasis of the recti, amounting to 15 cm. The incision reached from the xiphoid to the symphysis, and a large ellipse of skin was removed. The woman went to term and had a rapid labor, and at the time of publication—February, 1900—her abdomen presented a normal contour.

It is difficult to state to whom is due the priority in the use of the method. Piccoli does not state when his operations were done. The earliest record I can find is that of Sapiejko in December, 1898.

Some of the more apparent advantages of the method are:

1. The doubling of the abdominal wall at the hernial site.
2. The breaking of the lines of suture.
3. The broad surfaces for union.
4. The obliteration of the separation of the recti, and the reduction in the size of the abdomen. Its field is really not limited to herniæ proper, but also includes the treatment of pendulous abdomens, and of enteroptosis due to laxity of the abdominal wall.

Researches into the Active Substances in Typhoid Cultures.—A. Paladino-Blandini from his investigations concludes that: 1. Two substances, chemically and biologically different from each other, can be isolated from cultures of the typhoid bacillus; a nuclein and a nucleo-albumin. 2. The property of agglutinating the blood of inoculated animals, possessed by typhoid cultures, is dependent upon the presence of a special nucleo-albumin. 3. This nucleo-albumin used alone is capable of conferring an agglutinating property on blood. 4. Nucleo-albumin acts only by means of the leucocytes.—*La Riforma Medica*, April 17, 1901.

THE BORDERLAND OF INSANITY: WHERE AND WHAT IS IT?[1]

By HENRY WALDO COE, M.D.,

PORTLAND, ORE.,

CONSULTING ALIENIST, OREGON STATE INSANE ASYLUM.

To one who has passed from normal mentality into unsoundness of mind there was undoubtedly a moment distinctly dividing these two conditions—a moment which was bounded upon one side by that state medically denominated as sanity, and upon the other, and immediately following, that condition which is loosely comprehended by the term insanity. This is true, although those about the invalid may not have been able to fix the time or to name the condition or circumstances of advent of the latter state referred to. Years may have elapsed between the time when, upon one hand, reason, as apparent to all, was in control, and that, upon the other, when mental defectiveness ruled the individual. During this interregnum the most learned alienists, if called upon to decide, might have differed in their opinions as to the sanity or insanity in such a case.

Insanity, it has been said, strictly speaking, is not a state but rather a complex of symptoms, and even in its looser and current acceptation much might be gained by using, in a general sense, the term insanities. In a paper of the scope of the present one, there is no need of opening up the wide field which a discussion upon definitions of insanity beget; but for the purposes of practicability that wide area of mental territory situated between those known regions, of what is generally recognized as sanity upon one hand, and upon the other unsoundness of mind of such a degree that it is evident to the ordinary individual, has been and is known as the borderland of insanity.

The traveller in this region, generally a person harmless in character and habits, yet sometimes a menace to his family, friends, or society, and often a terror to his doctor, is known as the border-liner. At times near the boundaries of mental healthfulness, and again close to the line of mental darkness, he goes thus, perhaps months and years, hither and thither in this shadowy land, until circumstances, favorable or unfavorable, lead him out of it upon one side or the other. This region should not be considered as containing only those who are in the *stadium incipiens* of insanity, for an individual within its confines to-day generally is not, and in the future more often, if favorable circumstances attend upon the patient's suffering, may not be insane. This much as to where this land is. Let us now examine in some of its details as to what it is, beginning with the understanding that but a fraction of its features can be reviewed in a single paper upon so vast a subject.

No attempt will be made to cover the early manifestations of general paresis, although symptoms will be here given sometimes also found in that state. General paresis, as we well know, is deemed incurable when fully established; the belief being that at such stage destructive changes have intervened in the substance of the nervous tissue of the brain and elsewhere which have irreparably damaged the same, although in some cases, without doubt, much improvement is attainable. Harm is daily being done to persons suffering from a recoverable mental illness by a diagnosis of general paresis. The responsibility which a practitioner little acquainted with mental disorders assumes when he makes such a diagnosis is not always understood by him until what was deemed a hopeless mental wreck turns up in a restored state of mind to plague the doctor. Every institution in the land

[1] Read before the Portland Medical Society, November 21, 1900.

which receives mental diseases has many such cases upon its records. Permanent recovery did occur and evidently a mistake in diagnosis was made. The subject of general paresis is too vast, however, for the present moment, and will be treated later in a discussion to be devoted solely to that subject. The present paper will refer largely to those cases which, allowed to continue unchecked, tend to drift off into those mental disorders named by Krafft-Ebing the psychoneuroses—a class of mental disorders, even when fully developed, subject often to relief under the application of rational therapeutic, hygienic, and environal measures.

The most reasonable standpoint from which to gauge mental health is that which will permit a comparison of the individual's present methods, acts, manners, appearances, and speech with those formerly and usually held by him.

Millions of people suffer from insomnia who are not and are not to be insane. Insomnia is, in fact, we may all agree, the most distressing symptom of modern life. It is no respecter of persons or conditions, although more serious when occurring in those not of the higher walks of life. It is withal the most common prodrome of insanity, and the man who suffers from it may almost always be said to be travelling unpleasantly near the region of the borderland.

In a given case of insomnia let it first be determined how long the condition has existed. If it has been a habit of slow growth, becoming more pronounced as months and years have elapsed, and in an individual possessing no serious inherited mental or nervous defects—if in such a case the patient does occasionally get a good night's sleep and always obtains twenty-five or more hours of fairly restful sleep each week, while the physician's best efforts should be directed to the relief from the distressing features of this condition, a mental breakdown need not be greatly feared unless marked obsessions or other additional evidences of nervous impairment should be found engrafted upon the insomnia. If the patient is an elderly person, it should be remembered that many aged people sleep less than the younger, although this is not so in the more restful forms of age.

It matters not what the degree of ordinary care or anxiety upon a healthful mind may be, or how deep the grief, after a few nights of sleeplessness tired nature will re-assert herself with sufficient force to bring again to the weary brain refreshing sleep. When, therefore, an individual who has been an ordinarily good sleeper night after night for a week or more fails to obtain needed sleep, a comfortable bed and quiet surroundings having been provided, such individual is in need of a physician. If, in addition, there exists a neuropathic taint, the medical practitioner is dealing with one who, under proper care, may never become insane, yet who is now in the borderland of insanity.

There is generally present a restlessness in the borderland case of insomnia, even in the most depressed melancholic type, which is absent in other instances. There is an unmistakable sense of mental distress or the presence of an appearance of superlative pleasure in the serious cases which is quite characteristic, and which, to one acquainted with the insane, bears an omen of evil portent, clearly calling for prompt measures looking to the addition of nervous energy or the reduction of nervous tension as the individual case may require.

Many of these cases come within the pale of neurasthenia. They are true cases of nerve-cell fatigue; and while neurasthenia rarely leads to insanity, some of its phases place the victims thereto within the borderland.

The change of temperament in an individual is always suggestive of changing or changed mentality. A bookworm, somewhat abruptly and without advice from friends nor on account of any good reason, abandons his shelves. He takes long walks and spends most of his time out-of-doors. He becomes interested in baseball, goes to the races and bets his money freely. He does what in another might be a usual course of life, but which in him is unnatural and against every tenet of his social and private life. This man is operating under a new mental stimulus, and the change is too sudden to be healthful.

A man of probity and honor becomes all at once a public and notorious libertine. Heretofore careful in his manner of speech and living, he revels in obscene recitals and glories in the company of the lewd. He is in the borderland.

A gentleman was noted for his good general methods of living. He grew economical until within a few months he was denying himself the proper amount of food on account of its cost. When reproved for his habits in this regard, he gave an excuse which might have been accepted as reasonably satisfactory if the same had been adduced by one noted for parsimonious economy. He was not yet deemed mentally affected until other symptoms intervened, although he was considerably emaciated when he came under my care. In a few weeks he gained, under enforced feeding, both gastric and rectal, his accustomed weight and greatly improved in mental health, and his friends acceded to his requests for his discharge from the institution, and he returned to his accustomed labors, by no means, however, entirely recovered. His business life was an active one, for which he was not yet fully fitted, although to the uninitiated he seemed able to take up his work. His former normal manner of living, as to money matters, had been resumed. Two years later he began to spend money foolishly. He purchased unusual and unnecessary things and did not consider the cost, though this time his mental difficulty was much earlier discovered than upon the former occasion. His leading symptoms, as mentioned, were in opposite directions in the two attacks, but in both instances the change from the usual manner of living was quite noticeable.

A man began to collect oddities—nothing unusual in itself, but quite strange for this individual, who had all his life prided himself upon being a strict utilitarian. In a few months he had collected stuffed snakes, toads, and frogs to the number of several hundred, neglecting his ordinary business affairs to do so. Later he began to pick up stones of special sizes and shapes, and in a short time almost any stone he found possessed for him some peculiarity worthy of preservation. He was not obtrusive upon others with his newly found aspirations and delights, and to what an extent this habit of collecting stones had arrived was not known until complete mental breakdown ensued, when it was found that one room was nearly filled with barrels and boxes of the stones.

A man who had been a generous liver, and had always been in excellent health, one day announced himself as a vegetarian. This is a belief held by a large number of very excellent people, who, while their judgment may not meet with the approval of the greater portion of the scientific world, are not by any means considered insane. In a few weeks clothing made wholly or partially from wool, whether for under or outer garments, was discarded on the ground that as sheep were largely raised for mutton, the use of wool encouraged the raising of animals for food, and by the use of woollen clothing he became a party to "blood-drinking habits." The sentiment as to food soon developed into a desire for the reduction of all discomfort to animals generally. As animal life enters so promiscuously into the affairs of daily life, he studied

over every little matter, and suffered much for fear that in some way he was enjoying what had been a discomfort to some one or more of the lower animals. For instance, he had once seen an over-heavy car of coal hauled to the dump in a coal mine by the mule on service, and his memory of this event led him to eschew a coal fire for fear that a like experience accompanied most fuel of this kind. Wood he would burn, but he bought it in half-cord lots brought directly from the forest to his own house.

Soon this suddenly acquired sympathy for animals extended itself to the vegetable world. Wood now must have died before it should be cut and hauled for him. Grain with the germ in he would not eat. Potatoes, which became his leading food, he required should be shorn of their "eyes," the germinal elements, before he could be induced to have them cooked. The seeds of apples were carefully saved, and other like actions made his life a burden, and soon the cadaveric appearance so common in many of the ordinary vegetarian zealots passed into one of almost complete physical exhaustion and to apparent mental wreckage.

Anger as a habit is another of the symptoms of the borderland. It possesses a double import. First it is an evidence of nerve-cell instability, a condition in which the nervous organism, using a homely but striking illustration, is "set upon a hair trigger," which upon the slightest provocation "goes off"—in fact, a nervous storm ensuing, similar ofttimes to an attack of epilepsy, and in some cases coming on with like regularity.

"Anger," quotes the MEDICAL RECORD (April, 1898) from an English journal, "serves the unhappy mortal who indulges in it much the same as intoxicants constantly taken do the inebriate. It grows into a sort of disease which has various and terrible results. Sir Richard Quain said not long ago: 'He is a man very rich indeed in physical power who can afford to be angry.' It is true. Every time a man becomes 'white' or 'red' with anger he is in danger of his life. The heart and brain are the organs mostly affected when fits of anger are indulged in."

There is no man, perhaps, who is not at times provoked into anger, yet I am firmly convinced that every such attack, like one of epilepsy, tends to its own repetition, and in a like manner, under varying degrees, weakens normal mental equilibrium; that in every case it leaves its impression upon the mental armor, and not only tarnishes but also weakens it. While the majority of men can go through life without mental breakdown and yet be subjects of mental irritability and anger, some will from its influence fall if the habit is pronounced. A fit of anger, like the current against the breaking dam, tends to weaken the obstruction to its own flow, which is the second and more serious import of its presence.

There are men and women in every city who are within the shadow of the borderland as a result of the habit, and some of them are so deeply therein that it were better for others and no worse for themselves if some untoward circumstance should precipitate mental collapse, that detention and treatment might be instituted before, in one of these seizures, homicide or its attempt should occur.

I knew a man in this city who is pathologically subject to these attacks. They appear to have some regularity. The patient is morose for a day or two. His wife and children have learned to know of the approach of these fits, and sometimes by exercising the greatest care the violent paroxysm is hedged against; but usually in spite of their best efforts a vigorous passion does ensue. He curses his wife and beats his children, and in many instances has broken dishes, furniture, and windows, the unfortunate objects which have apparently acted as the climax of his complaint and ire. After the fit has spent itself he seems relieved. Sorrow follows for his violent acts. He repairs the broken furniture or replaces it with better, attempts amends to his family by presents and by supplying them with such amusements as he can find and afford, and remains fairly decent until the approach of the next attack. Formerly he could control his fits of anger if those outside the family were about, but of late years the presence of strangers scarcely restrains him. Twenty years ago the paroxysms occurred once or twice a year; now they appear as often as each month. If in one of these fits this man should kill some one, should he be held any more liable than if a like result had occurred in the post-epileptic frenzy? I scarcely believe so.

A patient is now convalescing under my care from an attack of melancholia. She is a widow, her husband having died under distressing circumstances two years ago, and over which she had constantly grieved up to the time of her full mental collapse, six weeks ago. She has been extremely difficult to care for on account of the wellnigh unmanageable character of her temper, which has necessitated a change of nurses on several occasions, and constant surveillance against accident at all times. This patient had been, when in good health, of excellent disposition, but for months before final breakdown had fairly grown quarrelsome, so easily was she provoked to anger. In fact, her friends were so thoroughly worn out in their attempts to live peaceably with her that this may have unconsciously influenced them in their determination to publicly commit her for State detention, in which the family physician, the county court, and all of her relatives except one had promptly concurred, on the ground that the case was too marked to expect cure, and that the expense of private care would be unwarrantable. The earlier anger in this case was not the indignant mental outburst of a person suffering wrong, but was the leading symptom in one who was then well into the borderland of insanity. This woman sat at home, day after day, with a picture of her lamented husband before her eyes, and anything which disturbed her mental reverie had grown to be a wilful obtrusion. If a complete change of environment had early been enforced, although perhaps necessarily against her own desire, the latter more pronounced condition almost certainly would not have occurred.

Constantly dwelling upon one theme will lead an individual into insanity. "A man of one idea" may bring success out of such theme, but it will be fortunate for him if success comes before reason takes wing. The ordinary meaning of this phrase does not imply its strictest application, but reference is had to an individual who in a multitude of plans or thoughts keeps one in the foreground. We do, however, occasionally meet a man who seems actually to have but one idea. Morning, noon, and night he dwells upon it, and finally becomes impatient when the affairs of life are forced in upon his purview. The more intricate the problem the greater the danger to reason. A young man who will talk and think of almost nothing except football will scarcely suffer, but the individual who ponders over a perpetual-motion machine, if the idea is long maintained, is wandering through the labyrinths of dark places leading to mental confusion.

The person who is subject to imperative ideas is often within the borderland. Dr. Edward B. Angell, in a paper read before the last meeting of the American Neurological Association upon the subject of "Imperative Ideas in the Sane," aptly says: "Imperative ideas are waking dreams which the feeble will is powerless to eliminate from the troubled field of consciousness; they are dependent for their mani-

festations upon a state of mental feebleness or insufficiency or cerebration, or instability of mental synthesis." While Dr. Charles H. Hughes, in a paper upon "Imperative Conceptions," would give to them their deeper psychiatric import as they increase in intensity when he says: "When such imperative conceptions pass the ordinary line of normal restraint into the uninhabitable realm of mental aberration, and become resistless expressions and acts violative of the proprieties and normal restraint of environment, and have a recognizable disease for their basis, they become evidence of insanity."

These obsessions are more common than is ordinarily believed, from the fact that the patient is generally sane and realizes that these feelings are unnatural; and their out-of-the-normal character leads often to their concealment for fear that they may be taken by the physicians as a symptom, true or false, of insanity. A patient now under my care had avoided a concourse of many people for fear that he would see some one in the company who would look like some one of his own friends; for on an occasion when such resemblance was noted he had great difficulty in restraining himself from imparting such fact to the stranger who was then before him. He never actually made a statement to this effect to any such person, but felt that the greatest self-restraint was necessary to refrain from doing so.

Upon one occasion, and once only, I was accompanied on a bicycle ride by a gentleman who was for the time being a patient of mine, who was excessively plagued by these obsessions together with a chronic fear of hereditary insanity. An imperative idea with this patient, when out-of-doors, was that he must read in full every sign which he should pass; and as artists of legitimate merchandise and of quack nostrums had been diligently seeking to outdo each other with inscriptions upon the fence-boards on the country along our path, my patient had much to do in reading all of them on both sides of the road; and although we rode leisurely, my companion was covered with perspiration on account of his efforts to prevent the escape of a single word from his view. Many times he was obliged to stop altogether to obey his imperativism. Once he appeared in tortuous agony because it had just occurred to him that he had not read completely what was written upon a small board which had been nailed upon the fence a half-mile behind us, calling attention to a carpet store, a matter of course then of no concern to him whatever. I suggested that he might read the announcement in full upon our return, whereupon he quickly mounted his wheel and rushed frantically down the road, calling back to me that he must read before going on, "for I might never live to come back this way."

These imperative concepts, compulsory ideas, or obsessions in the sane are based upon a loss of will power consequent upon a defect in the amount and force of residual nervous energy in the cortical cerebral cells. Dr. Henry J. Berkley, of Johns Hopkins, in his recent and excellent work upon mental diseases, speaking upon this subject says: "Except in extreme instances they [obsessions] are not to be regarded as evidences of insanity. The patients recognize their absurdity, and in a feeble way struggle against them, but the lassitude of will is too great to be overcome, and they return to their fears and anxieties. These fixed ideas are in contrast to those of the paranoiac, who believes all his false conceptions are true and have a basis in reality."

Recently, with Dr. Bower, of Salt Lake, I saw a patient whose obsessions took the form of fear of contaminations of the person with whom he should come in contact in shaking hands. This man felt that he should wash and scour his hands before accepting the hand of his physician or friends—quite different from nearly all who have a concept regarding uncleanliness, such individuals usually having a fear that they are themselves to receive such contamination.

The Grübelsucht of the Germans—the necessity of weighing with exact nicety both sides of every question, however trifling, before action—the disposition to count in doubles, the resistless impulse to touch or not to touch certain things, the repetition of certain words either in writing or mentally or orally, are not necessarily evidences of insanity, but indicate a condition either in or tending toward the borderland.

Needless to say, every user of opium, cocaine, and like drugs and the excessive consumer of alcohol are in the borderland, although no nervous symptoms of note may have as yet intervened. The young should be taught in school and elsewhere of the pernicious effects from the use of such drugs, although such education should not be of the character rendered in a medical course, in which familiarity seems to breed contempt; a writer having recently said that nearly one-half of all the users of opium and cocaine are found among medical practitioners, druggists, and trained nurses.

Many of those who are subject to protracted excessive masturbation are in the borderland, although this cause no doubt has been much over-estimated. The habit in boys and young men is often serious enough, but it does not seem to be as prolific of insanity as it is in girls. When we consider its very much greater frequency in males than in females, the proportionately greater influence of a mental character in the latter class becomes the more apparent. Sexual instinct is much more pronounced in the male than in the female, this fact being manifested in many ways, notably by the brothel, in which women and not men are demanded as the subjects for sexual hire. Woman as a sex is chaste, so markedly so that when one falls her weakness has a commercial value in the market place, quite different from that of her less virtuous brother. Woman is therefore the great conservator of the higher morality and of the major virtues of the race. She has a finer sensibility of the ethics of events than man. Her sexual operations are not dependent upon palpable physical expenditure. Exceptionally only does the woman enter into the sexual act with vehement completeness, and when she does do so the orgasm is largely nervous or psychical only. Fortunately for the moral integrity of the race is this true.

Because of woman's higher ethical sense the moral influence of a habit which she knows to be wrong seems to produce a much more depressing mental effect than the same habit does upon the male; therefore, although much less common in women, its effects when the habit is established seems more pronounced. How often have we seen the young man who has rather gloried in his sexual vagaries! How seldom is this noted in a woman!

As the consummation of the sexual act in a woman, normal or artificial, is largely psychical, so have I found in cases coming under my own observation that the ill effects following this habit in women have more often resulted, not from the habit itself, but from the effect upon the mind of the habitué, from constantly dwelling upon the subject. More often have I witnessed mental misery in women in the higher walks of life as a result of remorse and fear over the habit indulged but a few times, than in others of the less favored classes, in whom the habit has been carried on even to great excess. In either of these cases, however, the patient is in the borderland.

A man who had been married for twenty years during the first ten years was engaged in a business which kept him much from home, occasionally for months at a time. His wife came under my care for melan-

cholia. She said that during these first ten years she had, while her husband was absent, upon not to exceed a half-dozen occasions in all, relieved sexual excitation following menstruation by masturbation. She was in fair general health, although she had long continued to mourn over her supposed complete physical breakdown, a result of the lapses from conjugal constancy already referred to. None of us, I am sure, would attach any great importance to the lapses from marital rectitude in this case other than the physical weight which their occurrence had exerted for years upon the mind of this distressed individual.

Some years ago I was consulted by the wife of a clergyman, then three years married, who was clearly within the borderland through worry over the sinfulness of a similar habit, which had been indulged in for a few months, somewhat regularly some years before her marriage. She had lost much flesh, was sleeping badly, and felt that the decline into which her habit had brought her was the natural and unavoidable outcome of the indulgence of a few dozen times, from which she had felt no physical results until a few months before my attention was called to the case. The habit evidently had no influence upon her condition, except through her mind.

On the other hand, the extent to which some women will go in the habit of masturbation is certainly remarkable, and some of these cases go on into dementia, their habit being almost impossible to overcome. One such case under my own observation would effect her object in spite of every effort to overcome it, which seemed to be the last volitional act in her dementia, accomplishing her purpose, if no other means was possible, by the friction of one thigh against the genitalia. This woman had been twice married, but she had never ceased to masturbate. She had informed members of her own family that the normal sexual act had no interest to her, and that after submission thereto she was always in the habit of seeking gratification for her own desires by manual titillation. With her second husband she had finally required, as a condition precedent to the gratification of his desires, that he should first render such unnatural service in her behalf. She often repeated a statement in her illness, probably a delusion, that she had been taught the habit by a physician while she was a girl, he having informed her that this was advisable to relieve her sexual excitation and to prevent a worse lapse from virtue. This was either a remarkable delusion or extremely reprehensible medical advice.

Prolonged excessive sexual indulgences, no matter how normally accomplished, sends multitudes into the border land. In fact, of all who enter and yet turn aside into the field of mental healthfulness before breakdown has overtaken them, I believe that more than a majority of the travellers in this realm between mental vigor and mental decay belong to this class. Sexual excess is of course a relative term, for what would be moderation in one would prostrate another. That sexual overindulgence is a drain primarily upon the nervous system is manifested in many ways, and by none more so than by the well-known fact that ordinarily he who has much literary work of a high order to accomplish, must, whether he would or not, husband carefully his sexual expenditures.

There seems to be a wise provision of nature by which the phenomenally developed sexual individual in marriage is almost always mated with one possessing to a marked degree less power and proclivities in this direction. After the first blush of newness has worn away, the amorous individual finds that moderation must be maintained on account of the capacity or wishes of the partner thereto, or on account of numerous other reasons always present. Family trouble is almost certain to follow the weakened mental equilibrium of those who persist to sexual exhaustion, so that rest eventually comes, and generally before the mental breakdown is complete, but not always so. Excesses outside of the family state, where the opportunities are present to an unlimited degree, act even with greater force in weakening the nervous vitality, the moral effect of the surroundings accentuating the debility derived from the excessive sexual activity itself. Every physician long in practice has been consulted by some husband, who has complained that his wife has no interest in the sexual act except as one of accommodation for him, and the statement has often been advanced that such a man and such a woman were mismated. I feel that sexually mismated individuals from a neurological and psychiatrical standpoint are always found in those occasional cases where both man and woman possess strong sexual passion and capacity and little self-control, for these people almost always, sooner or later, come into the borderland of insanity.

Many of you will remember a case reported here a few years ago by two members of this society, one of whom was the physician of the man and the other of the woman in the case, the family having separated, in which the completed sexual act as to both parties had been entered into and completed upon an average of five times daily for fifteen years of their married life. These people had for years been in a mental condition closely bordering upon insanity as a result of their excesses, jealousy being the leading symptom of their respective states. The man at the time explained to me, with much shame and regret, that while his disposition was as energetic as formerly, with advancing years his ability would now no longer permit him to complete the sexual act "more than three times a night." The wife sought separation on the ground of infidelity, her only specific claim being that this failure upon her husband's part was evidence that he was expending his sexual power elsewhere. She refused to believe, using her own feelings and desires in this regard as a positive proof, that the age excuse was a valid one.

Another case of excessive sexual expenditure came under my observation last year. The woman in the case, when seen by me, was a sufferer from a pronounced nervous irritability, having lost nearly forty pounds in weight during four months of her then married life. The husband was extremely nervous, both being border-liners. The woman had lost a previous husband three years before, after a few months' illness. The present married life had been full of quarrels, increasing in intensity until she had, just before I first saw her, left her husband and returned to her mother's home.

The story which these people told regarding sexual matters, although over a much less period of time, exceeds anything of which I had heretofore ever heard. The husband stated that he had not returned to his work since marriage, but had remained at home nearly every hour, which seems probably true. He said that during the earlier weeks the number of completed sexual acts had exceeded during each night ten in number, with numerous indulgences during the daytime, and that at the time his wife left him the total sexual expenditure had become reduced to an average of ten times only during the entire twenty-four hours. He also made the startling statement that he thought that this was excessive, but that he could not do less and live in any kind of peace with his wife. The wife, who acknowledged herself the greater aggressor in this sexual contest, said that her husband had named the number of acts of coitus fully completed by both at too high a figure, and that they did not exceed eight or nine times during the twenty-four hours, although she said that occasionally she was herself

unable to complete an orgasm, and that she then required another attempt upon the part of her husband at the moment earliest possible for him to re-enter the sexual state. It seems to me probable that the truth in this matter could be reached by taking a mean figure between their respective statements, so that it is quite likely that these people had averaged one completed sexual congress every two hours for a period of four months. Claims are always to be discounted when matters of this kind are under discussion, but as one of the individuals in each of these cases had a motive in making as light of the matter as possible, it would seem probable that the figures relative to the habits in these two instances might be taken to be reasonably correct. We may wonder less at the grossly disgusting sexual excesses which they portray than at the extremely unusual capacity of the individuals referred to. The individual who indulges once or twice a month, as many times a week, or even nightly, will almost seem impotent when compared with such sexual monstrosities.

Quite in contrast with such instances, yet none the less a border-liner from sexual excess, was a man whose case came under my observation, where sexual congress entered into once fortnightly invariably would intensify nervous symptoms to a distressing extent. This individual would enjoy a comfortable state of health indefinitely so long as he would refrain from sexual expenditures exceeding once monthly, but depression would continue for several days following a more frequent act. This feeling I believe was real, not fancied, for an attempt was made for months to dispel the belief, and although other symptoms, obsessions, did disappear under treatment, medical and moral, the sexual peculiarity remained as before.

Much space in this paper has been taken up with the sexual phase of the subject, because, as before stated, I regard it as the most important causative factor touching the subject of the borderland of insanity. The erroneous belief in and out of the profession, that sexual expenditure is necessary for the maintenance of good health, is, I also believe, one of the fallacies which magnified has had much to do with the encouragement of sexual excesses. Where one individual becomes insane on account of the need of sexual intercourse, if such a case has actually ever existed, thousands become border-liners and a hundred become insane through excesses and syphilis or other resultants of the promiscuity of current habits along this line. Physicians should not neglect to impress this fact upon young men when the opportunities to do so present.

While it would not be feasible to attempt to cover in a general paper, such as this, the subject of the medical treatment for those who are border-liners, this phase of the subject is most important. These people are moving on betwixt mental health and madness, and if we shall do our whole duty by them the latter stage generally may be avoided. Something else than a word of reassurance is indicated to effect their recovery. Every case should be made an object of special investigation, and a course of treatment instituted commensurate with the extreme gravity of the situation. There will not usually be found any short cut to the normal side of the equation, for, regardless of what the cause may have been, the nervous symptoms which we find represent the result of influences so powerful or of such long duration that there is no ground for expecting such prompt results as might follow the treatment of some acute ailment.

Not only should the cause of the trouble be removed, but the patient and the environment in which the cause has been operative should, so far as possible, be separated. The very best hygienic, dietetic, and reconstructive measures should be invoked in the patient's interest. Work should generally be abandoned or changed, complacency of mind encouraged, and new currents of thought suggested and enforced. Moderation should be directed in all things.

Under these methods of care, together with such special regulations as may in each case be indicated with patient supervision of the changing condition of the sufferer's mind, leading it gently but firmly in the proper direction, we may, after a lapse of sufficient time, witness full mental vigor in one who without such treatment and training might otherwise drift into fully developed insanity.

RECURRENT OCULOMOTOR PARALYSIS: REPORT OF A CASE, WITH REMARKS.[1]

By WILLIAM M. LESZYNSKY, M.D.,

NEW YORK,

CONSULTING NEUROLOGIST TO THE MANHATTAN EYE AND EAR HOSPITAL, ETC.

M. N——, born in the United States, single, twenty-nine years of age, and a type-setter by occupation, was first seen by me December 6, 1900, through the courtesy of Dr. David Webster.

She was in good health until her sixth year, when she began to have attacks of headache confined to the right temporal and supraorbital regions, which were invariably accompanied by vomiting. The attacks occurred every five or six weeks. At her twelfth year, the customary paroxysm was associated with ptosis of the right eye, from which she recovered in two weeks. The migraine continued to recur every five or six weeks.

[1] Paper read and patient shown before the New York Neurological Society, April 2, 1901.

The second attack of oculomotor paralysis took place in her nineteenth year, with the usual orbital, supraorbital, and temporal pain and vomiting. There were partial ptosis, diplopia, and inability to look upward with the right eye. Much improvement followed in three weeks, but the eye did not move upward so well as before. Complete recovery of motility ensued at the end of a few months, and she remained well save the attacks of migraine.

The third attack occurred in her twenty-second year. Almost complete ptosis was present; the eye deviated outward; diplopia existed. She was obliged to keep the affected eye covered for nearly three months. Recovery ensued in about one year.

The fourth attack came on in her twenty-seventh year (two and a half years ago), similar to the third attack, and lasted three weeks.

The fifth attack occurred three weeks ago, with headache, vomiting, and the same eye symptoms. She now complains of the eye turning outward and her inability to look upward.

Menstruation began in her fifteenth year, but the periodical attacks of headache, etc., bear no relation to this function.

Examination shows slight drooping of the right upper eyelid, paralysis of the superior rectus, and paresis of the inferior and internal recti. The right pupil is 5 mm. in diameter, and rigid; the left pupil 3.5 mm., and the reaction is normal.

There is no diplopia as she suppresses the image in the right eye. The motility of the left eye is normal.

The vision of both eyes is $\frac{20}{20}$ and the visual fields and ocular fundi are normal. The result of further examination is negative as to the internal organs and nervous system. Her general condition is that of anæmia and neurasthenia. The family history has proved unimportant. The ocular condition is practically unchanged since the first examination.

This condition has been variously described as "ophthalmoplegic migraine," "intermitting paralysis of the third nerve," "recurring oculomotor palsy," and "periodical oculomotor paralysis."

The cardinal symptoms are, the unilateral character of the headache, the limitation of the ocular paralysis to one side, the pain and paralysis being on the same side, the involvement of the same nerve in all attacks, the frequent involvement of all branches of the nerve, and the intervals of complete freedom.

The most interesting features in this affection are the comparative rarity of this type of oculomotor palsy, and its pathology.

The literature upon the subject is abundant, and shows great diversity of opinion as to the causation of the involvement of the nerve.

I have seen four other cases. My first case was that of a young woman twenty years of age, who presented herself for examination in 1886. There was complete paralysis of the third nerve, with a clear history of the accompanying attack of migraine. Electrical treatment to the eye was instituted, and she recovered in three weeks. Her mother subsequently told me that the patient had two previous attacks of a milder type, from which she soon recovered after using cold-water applications to the eye. The last attack was more severe and lasted over a week; she had, therefore, concluded to seek medical advice. I saw the patient three years later, but there had been no recurrence.

This particular instance is mentioned in illustration of the tendency toward spontaneous recovery, which is also frequently observed in certain other forms of paralysis of eye muscles, although the restitution of normal function is often erroneously attributed to some special form of treatment.

In many of the reported cases, in spite of the recurrence of the paralysis, the patients have ultimately made a complete recovery, both from the attacks of migraine and the accompanying third-nerve affection.

But the outcome is not always so fortunate; for in others the paralysis gradually increases during the intervals and ultimately becomes permanent, thus excluding the admissibility of the vague terms "reflex" and "hysterical" in the description of its etiology.

Only two authentic cases of recurrent oculomotor palsy have been studied post mortem: one by Richter in 1887 (*Archiv f. Psychiat.*, xviii., p. 259) and the other by Karplus in 1895 (*Wiener kl. Woch.*, Nos. 50, 51, 52). In the former case, a fibro-chondroma was found in the course of the nerve trunk at the base of the skull, separating but not destroying the nerve fibres. The patient was a man who developed epilepsy in the course of the affection, and died of pulmonary gangrene. In the second case, there was a neurofibroma of the motor oculi at the base. The patient was a woman who died of paretic dementia. Karplus therefore concludes that the cause of periodical oculomotor paralysis is a palpable anatomical change (probably congenital) at the base of the brain, in the region of the root of the third nerve.

It will thus be seen that patients with this form of ocular paralysis invariably suffer from attacks of migraine, which seem to be fortuitously complicated by the presence of a small neoplasm limited to the course of the nerve at the base of the skull. It has been assumed that the cerebral hemisphere (on account of its increased vascularity during the attack of migraine) presses the tumor against the unyielding cranial base, thus interfering with the conductivity of the nerve.

Without the essential history of the patient in regard to previous attacks of oculomotor paralysis, and their association with migraine, this unusual form of disease would pass unrecognized.

56 East Fifty-eighth Street.

Hydatid of Heart.—A. Jeffreys Wood reports the case of a man in apparently robust health, who died suddenly while riding a bicycle. At the autopsy, the heart was seen to occupy the greater part of the chest, neither of the lungs being visible. The pericardium was closely adherent to the surface of the heart, but with a little force was detached; toward the base of the heart on the left side a white patch showed toward the pericardium, and as the covering was lifted from this part a daughter-cyst, the size of a large marble, escaped from a large mother-cyst in the left ventricular wall. In removing the heart about a dozen daughter-cysts escaped, two of them being as large as bantams' eggs. A small cyst was found on the liver, and another in the centre of an adhesion running between the lower edge of the liver and the duodenum. The rest of the organs were healthy.—*Intercolonial Medical Journal of Australasia*, March, 1901.

Digestive Leucocytosis.—A. Japha says that three theories have been held concerning the post-digestive rise in white blood cells: (1) That a digestive leucocytosis occurs after every meal; (2) that there is a daily ebb and flood in the leucocyte tide, the maximum usually being after the main meal, but persisting even in starvation days; (3) that after a period of starvation the number of leucocytes is increased by a meal rich in animal albumin. As the result of his own observations the author concludes that while the taking of food has some effect on the leucocytosis it is in the main a periodical event occurring in the afternoon and not greatly influenced by starvation, the omission of one or more meals, or by changing the heaviest meal from the middle of the day to the breakfast or supper hour. Contrary to the older beliefs, the in-

crease is not a lymphocytosis but a simple polynuclear leucocytosis, already existing cells being evidently drawn from the cytogenic organs into the circulation.—*Deutsche Aerzte-Zeitung*, April 1, 1901.

Laceration of the Vaginal Vault during Labor.—M. Kaufman finds that about one hundred cases of this casualty have been reported in the literature. According to some authors its gravity keeps pace with its rarity, and it is to be considered more dangerous even than rupture of the uterus, owing to the fact that the latter viscus is contractile and tends to favor spontaneous apposition of the torn edges, while the lax vaginal walls afford no obstacle to the prolapse of the intestine. Regarding treatment opinions are still divided. Laparotomy, simple tamponnade, suture through the vagina, and hysterectomy have all been recommended and practised by various operators. The author believes laparotomy indicated in those cases in which the fœtus is wholly or in part in the abdominal cavity, and also when the bladder is torn or the hemorrhage cannot be checked from below. In most other cases the rent is to be sutured through the vagina, but when the application of sutures is unusually difficult or there is evidence of already existing infection, the wound is to be drained and the vagina packed with gauze.—*Monatsschrift fur Geburtshülfe und Gynäkologie*, April, 1901.

Guaiacol in Gonorrhœal Epididymitis.—B. Goldberg gives this agent the highest rank in discussing the many methods of treatment that have been advocated for this affection. It is best applied in a twenty-per-cent. ointment, which may advantageously have as a base equal parts of lanolin and resorbin. This is to be used twice a day after a single preliminary sitz-bath; the dressing is completed by covering the anointed surface first with a compress, then with absorbent cotton and rubber tissue, and finally applying some form of suspensory bandage, which secures perfect fixation of the scrotum. According to the patient's general condition, he is allowed to go about his business, or is simply kept quiet, or is sent to bed, but under the guaiacol treatment the latter is never required for more than three or four days. Internally gr. xlv.–lx. of salol is given daily.—*Centralblatt für innere Medicin*, April 6, 1901.

The Bactericidal Action of the Saturated Solution of Sodium Chloride.—Francesco Testi concludes that this solution has a bactericidal action on various pathogenic germs, this action being favored by a high and constant temperature. The resistant power of bacteria to sodium chloride may be thus classified in a descending scale: Cholera bacillus, Finkler's bacillus, typhoid bacillus, diphtheria bacillus, glanders bacillus, and the pyogenes aureus. This applies when the temperature is above 36° C. The germ of contagious anthrax offers a weak resistance to sodium chloride, losing its vitality after one day's exposure to its action. The bacillus subtilis, on the other hand, offers a prolonged resistance. The skin of carbuncle does not lose its virulence even after twenty days' action of sodium chloride.—*La Riforma Medica*, April 2, 1901.

Tetanus.—Thomas C. Craig says that in the treatment of this disease the cardinal points to be kept in mind are: (1) To treat the wound locally; (2) to try to eliminate the absorbed toxin by the kidneys, the skin, and the bowels; (3) to support the vitality of the patient; (4) to select and apply remedies so as to act on the motor cells of the cord and brain, or to antagonize the action of a toxin by an antitoxin. H. C. Wood, Jr., finds that carbolic acid gives better results than does the antitoxin treatment. It antagonizes the toxin and quiets the nervous system. It should be given hypodermically and in large enough doses (0.72 gm. daily for an adult, beginning with 0.2 gm. at two and three hours' interval, rapidly increasing the dose to double and triple the quantity; a two-per-cent. solution being used).—*The Medical Examiner and Practitioner*, April, 1901.

No Specific Cure for Tuberculosis.—E. H. Smith says that change of climate has less to do with bringing about a cure than plenty of money with which to obtain everything necessary to extreme comfort. Excesses which may creep in as a result of the fortunate possession of money in plenty will defeat the cure. Change of climate at the proper time of the year, and ordered by a physician who has travelled extensively himself through the various places regarded as "health resorts," will perhaps be of benefit by toning up the appetite, interesting the mind, and giving the patient something to take up his time. To send a patient who, perhaps, possesses scanty means, to a barren country with nothing to look at but sagebrush, cactus, and bare hills; to put him in an uncomfortable boarding-house filled with other unfortunates like himself, sent there to cough out a miserable existence, is inhuman. A patient under such circumstances sees nothing but gloom and suffering. He gets improper food, a cold room, and a poor bed. He goes out weak and delicate, to rough it like a healthy laborer. Worse than all, nearly always by the advice of a doctor.—*Pacific Medical Journal*, April, 1901.

Hysterical Astasia-Abasia in a Child Aged Two Years and Four Months.—M. W. Hoge reports the case of a child two years and four months old who was ill with bronchitis for nearly four weeks, becoming considerably reduced in flesh and strength. For about a month after she asserted an inability to walk. Careful examination demonstrated the absence of any signs of organic disease which could cause such disability. She moved the legs freely when sitting, and the amount of muscular resistance which could be offered to passive movements showed that the difficulty was not due to muscular weakness; no muscular atrophies and no pain or anæsthesia could be demonstrated, nor were there any evidences of disease of the bones or joints. The tendon jerks were present in about the normal degree; no vesical or rectal disturbances occurred. When placed in a standing position, she became much agitated mentally, cried out that she could not walk, stiffened the legs and extended the feet so as to stand upon the toes, exerting sufficient strength to maintain herself in this position for a minute or more, and if supported walked with ataxic movements of the legs. While being examined, if asked to grasp something with the hand she protested an inability to do so, but ordinarily used the hands very well. As her physical condition improved the difficulty in walking diminished, and after about a month disappeared, since which time she has continued well.—*St. Louis Courier of Medicine*, April, 1901.

Inheritance of a Gouty or Uric-Acid Toxæmia in Children, with Statistics of Fifty-seven Cases.—C. N. Brandt calls attention to the apparent inheritance in children of a tendency to the retention of uric acid. He presents a table of fifty-seven cases of diverse manifestations of the retention of uric acid; the noticeable points being, first, that in all the cases an age had not yet been reached when it is probable the patient could have acquired gout or uric-acid toxæmia; secondly, that in each case either one or both parents gave histories of uric-acid poisoning; thirdly, that the cases in which there was a paternal history were just one hundred per cent. greater than those with a maternal history. The individual histories of the children showed that so long as they were properly fed and

given plenty of physical exercise, so long they remained well; but the moment any indiscretion in diet, etc., was allowed they developed a condition in which uric-acid retention could be demonstrated and which yielded promptly when the normal uric-acid excretion was again established. The various manifestations comprised eczema, indigestion, urticaria, pharyngitis, tonsillitis, joint inflammation, nasal catarrh, asthma, conjunctivitis, dental caries.—*Pediatrics*, April 15, 1901.

Albuminuria due to Constipation and Diarrhœa.—B. Stiller has for twenty years devoted much attention to this form of albuminuria. His observations show that there exists a non-inflammatory catarrh of the stomach and intestines, attended by the appearance of albumin and casts in the urine. The author holds that the loss of water by diarrhœa accounts for the albuminuria to some extent, but that some toxic influence is undoubtedly also present. There is a lessened water supply in cases of constipation, owing to diminished ingestion of foods and fluids.—*The Medical Echo, Budapest*, April 1, 1901.

Paralysis Agitans without Tremor.—Augustus A. Eshner describes the symptoms of this affection, the chief one of which is usually the tremor. It is, however, not absolutely constant, and its absence does not invalidate the diagnosis. The impairment of mobility is no less distinctive than the tremor. The author reports two cases of paralysis agitans in which the tremor was not absolutely absent, but was so inconspicuous as not to be viewed as a symptom of importance, much less of diagnostic utility. He invites renewed attention to the fact that the disease under consideration may be unattended by tremor, and further that this, when present, may be accentuated by voluntary action.—*Pennsylvania Medical Journal*, April, 1901.

The Etiology of Dysentery in Temperate Climates.—A. Castellani reviews the investigations made in this line by Celli in Italy and Krause in Germany. The former holds that a special form of the colon bacillus is the chief factor in the causation of the disease. This variety is different from the bacillus coli communis, not by its morphological characteristics, but by the properties of the toxins produced. Krause isolated from the fæces of dysentery a bacillus which he has found to be constant in all recent cases of the disease. It possesses very distinct characteristics, such as immobility; it does not liquefy gelatin, nor coagulate milk, nor produce gas in a mixture with sugar. The author holds with Krause that this bacillus is the true agent of the dysentery at present existing in Germany. Investigations in other countries should be pursued in order to ascertain whether the dysenteries of all European climates are etiologically similar.—*Rivista Critica di Clinica Medica*, April 13, 1901.

Puerperal Mastitis: its Prevention and Treatment.—Edward P. Davis declares that the most usual cause of puerperal mastitis is infection. Tuberculous infection of the female breast may be properly suspected in cases of chronic tumor with a serous discharge, in a patient of tuberculous tendencies, and in whom the tumor grows slowly but steadily. If pregnancy should occur, the tumor would probably rapidly increase, and a mixed infection with pus formation very probably take place. Suppurative inflammation of the breast may be feared in patients who have had inflammation in the breast at any time before becoming pregnant. Puerperal mastitis tends to recur with each confinement. A traumatic lesion of the mammary gland also predisposes to puerperal mastitis. Infected cracks or fissures in the nipple remain by far the most frequent sources of puerperal mastitis. The breast and nipple should be washed with castile soap and warm water, the nipple drawn out by the thumb and finger, and a suitable antiseptic ointment applied. Stasis of milk in the breast must be prevented. To preserve the nipples in an aseptic condition, boracic acid is the most available antiseptic. In neglected cases infection may travel into the axilla, and axillary abscess occur. It is sometimes better to err on the side of too early incision than to delay too long. It is undoubtedly safer not to give the child milk from an infected breast. The same germs which infect the breast may infect the intestines, and the milk should be pumped from the breast and not given to the child.—*The Therapeutic Gazette*, April 15, 1901.

The Climatology of Neurasthenia.—F. Savary Pearce says that there are two extremes to be avoided by the neurasthenic invalid, namely, a low, windy, treeless country, and one characterized by constantly quiet atmosphere, high altitude (above two thousand feet), with low atmospheric pressure. Localities where heavy storms are prevalent are to be avoided, as are districts menaced by high winds and frequent fogs; low country with continuous, non-varying, although moderate heat. A sea voyage is usually an excellent preliminary to other climatic measures. The author regards the Maine country about the Rangeley Lakes as almost ideal for neurasthenic patients, having an altitude of six hundred to one thousand feet, with a rare combination of sea and pine-laden atmosphere conjoined with plenty of sunshine, all mildly stimulating meteorological conditions. Next in order in America he places the inland country of New Brunswick and of Nova Scotia; third, the gravelly and stony country in the United States and Canada, the great lake regions of Ontario, Wisconsin, and Michigan, stretching east to the Muskoka Lakes and about Lakes Simcoe and Nippissing. The author gives a table of altitudes of some places near at hand where it is desirable to send neurasthenic convalescents. These include several places in the Adirondacks, Lake Chautauqua, Lake George, Lake Hopatcong, and Harvey's Lake, Pennsylvania.—*Pennsylvania Medical Journal*, April, 1901.

Electrolysis in the Destruction of Organized Strictures of the Eustachian Tube.—J. A. Kenefick discusses the relative advantages of this method of treatment and answers some of the objections brought against it. He concludes by saying: (1) That it cannot be foretold exactly in any given case just what result will follow this treatment, as this will depend largely on two comparatively unknown quantities, viz., (*a*) the vascularity of the tube lining and its toleration of the mechanical and electrical interference, and (*b*) on the degree of tympanic involvement; (2) that tubal obstruction is early present in the great majority of cases of so-called chronic hypertrophic catarrhal otitis media, and that progressive deafness, tinnitus, and vertigo, and many of the peculiar and distressing head symptoms may be purely mechanical, dependent upon closure of the tube by an organized obstruction, while the tympanum and its structures are yet free or only slightly involved; under the latter circumstances brilliant results may follow restoration of the tube's patency; (3) that in any case in which Eustachian obstruction has become organized the best means of disintegrating and causing its reabsorption is by the electrolytic bougie, which in rapidity, efficiency, and permanency excels all known methods.—*Archives of Otology*, April, 1901.

Bicycling in Gastric Disorders.—Fürbringer is a warm advocate of the moderate use of the bicycle in a considerable proportion of stomach diseases. The conditions that most positively contraindicate this

form of exercise are carcinoma and ulcer, and for patients suffering from these affections nothing but harm can result from its use; but, on the other hand, the benefits it brings to less grave disorders are many. At the head of the list stand the nervous dyspeptics and those complaining of habitual lack of appetite without organic disease. In these patients the effect of judicious bicycling is often marvellous, and far exceeds the best results of the most carefully considered medication. Other forms of sport, horseback-riding, running, swimming, rowing, etc., no doubt would equally stimulate metabolism and elimination; but they are all too violent to be permissible for semi-invalids or neurasthenics; while bicycling excels walking, the only other form of exercise that can be compared with it, in the fact that it is so much more economical of time, *i.e.*, that the feeling of well-being and pleasant relaxation following a long walk can be produced in half the time awheel, with the further advantage that the sense of fatigue will be less. Undoubtedly the psychical factor also plays a large part in the happy results, and it is needless to recapitulate the tonic effects of the fresh air, mental diversion, etc., that are involved. The only caution required is that the cases be carefully selected and that moderation be insisted on.—*Zeitschrift f. diätetische u. physikalische Therapie*, vol. v., No. 1.

Tendon Transplanting in Paralytic Deformities.—Clarence L. Starr believes that one cannot claim that the operation will cure, or even be applicable in all cases of paralytic deformities, but it is certainly worthy of a large place in the treatment of these cases, for by its use some are completely cured, and in others it allows of the substitution of a simple form of support for a more complex one. The operation is undoubtedly indicated in those cases in which a group of muscles is left unimpaired, while the opposing group is paralyzed. The foot and the leg are the members to which this treatment has been chiefly applied. Cases in which the operation has been done on the arm have been reported. The author is convinced that in this operation—which consists in rearranging the attachment of the healthy active muscles so that they may act to better mechanical advantage, thus giving the greatest measure of support possible, with the limited muscular activity—a great deal may be done for this otherwise hopeless class of deformities, and with greater experience much better results may be expected. Primary healing must be secured in order to gain success. The tendons should be united by a crucial mattress suture, of kangaroo tendon preferably. Motion should not be allowed till about the fourth week. Goldthwait's plan of dividing the paralyzed tendons, and inserting them into the active ones, is probably preferable to the opposite procedure.—*The Canadian Practitioner and Review*, April, 1901.

On Sounding and Irrigating the Frontal Sinus through the Natural Opening.—W. A. Wells says that successfully to sound the frontal sinus, one must have a probe bent at 3 cm. from the end, which should be rounded, and at an angle of about 100°, though capable of being flexed to a greater or less extent to suit individual differences. Using the uncinate process as the guide (resection of the anterior end of the middle turbinate is necessary in some cases) to begin, apply the beak of the probe well backward in the hiatus, and draw it forward and upward in the direction of the sinus at the same time that the handle is depressed. If it does not slip easily into the cavity, do not use force, but holding always the probe lightly in the hand, reintroduce, feeling for the ostium with the beak a little in front of the hiatus. If the sound be in place one will be aware of it by the following tests: (1) The probe will have penetrated such a distance as to measure more than 6 cm. (between 6 and 7 cm.) from its extremity to the point where the handle is in contact with the anterior border of the floor of the nose; (2) the direction will be such that it makes an angle of about 60° with the floor, or, what is the same thing, the handle makes such an angle with an imaginary, horizontal line or plane, continuing the floor of the nose forward; (3) the beak of the probe will be directed forward (as shown by the ring indicators on the handle); (4) the handle will permit of a certain amount of rotation.—*The Laryngoscope*, April, 1901.

Some Interesting Results of Thyroid Medication.—A. Rivière reports three cases in which he believes that the thyroid functions were perturbed by cancer, by the advent of the menopause, and by influenza respectively. They were certainly not cases of aborted Graves' disease. The administration of iodothyrin caused subsidence of pain, diminution in the enlarged circumference of the neck, and improvement in the general symptoms.—*Medical Press and Circular*, April 24, 1901.

A Family Streptococcus Infection after Influenza.—A. Huber reports the histories of twelve members of one family, of whom seven were newly vaccinated. The whole family except three of this number sickened with influenza, and all of those who had been both vaccinated and had influenza developed buboes in the axilla of the vaccinated side. On incision these were found to contain pus rich in streptococci. The author thinks there was present some unusual infection, the vaccinated arm making a locus minoris resistentiæ permitting the development of acute symptoms in the corresponding glands.—*Correspondenzblatt für Schweizer Aerzte*, April 15, 1901.

The Results of Inoculating the Brain with Micro-organisms Taken from the Nasal Cavities and from Suppurations of the Middle Ear.—Oliviero Barrago-Ciarella gives the following results from a series of experiments: 1. Some of the pathogenic organisms taken from the nasal fossæ produce no effect when inoculated subcutaneously. 2. When injected into the brain they cause death. 3. Certain micro-organisms in small number cause death when injected into the brain and when injected in much larger numbers subcutaneously. 4. Micro-organisms taken from the cavities of the ear are pathogenic even when injected under the skin. 5. In smaller or larger amount they are always fatal when injected into the brain.—*Giornale Internazionale delle Scienze Mediche*, April 15, 1901.

Jaundice in Children.—George F. Still considers the subject of jaundice in children, chiefly with reference to prognosis. He cites several cases of icterus neonatorum in which, instead of lasting a few days, the jaundice lasted more than two months, and then passed off, leaving the infant apparently none the worse for it. Jaundice of the new-born with congenital syphilis is usually fatal. The prognosis is also bad in congenital obliteration of the bile ducts. Cirrhosis may occur in children, usually between the ages of four and thirteen, and in many, if not in most cases, there is no connection with alcohol. A fatal result occurs in two or three years from the appearance of the first symptom. Jaundice also occurs as a complication of various conditions such as heart disease, pneumonia, tuberculosis. In the first instance it is not necessarily fatal, but is of grave significance in pneumonia and tuberculosis.—*Medical Press and Circular*, April 24, 1901.

MEDICAL RECORD:

CHRISTIAN SCIENCE VIEWED THROUGH THE SPECTACLES OF A LAY WRITER.

THIS cult, fad, or whatever name may be most fittingly applied to the dogmas of the new sect, has not only crossed the Atlantic, but is even said to be making considerable headway among a certain section of the British public. The converts to this recently discovered doctrine are exclusively members of that class known as society, and presumably mainly of the weaker sex. The explanation given of this sudden interest on their part in Mrs. Eddy's teachings is that the wholesale slaughter of sons and relations in South Africa has driven the mourners to draw consolation from some spiritual source. Christian faith does not fill the void in their souls, because to the majority of them true religion is a sealed book; therefore solace is sought wherever it may seem most easily to be found.

Christian Science has had full and exhaustive discussion in this country. In Great Britain literature treating of the matter has been merely congruous to the meagre sympathy evinced by the people for the views set forth by Mrs. Eddy and her disciples. The dissemination, however, of these principles on a widespread scale is now compelling the attention of English writers, and one of the brightest of these has just delivered the sanest opinion on the subject which has as yet been printed. The journalist in question is contributing a series of articles upon Spiritualism in general, and Christian Science in particular, to the London *Referee*. He has been reading Mrs. Eddy's book, and after criticising her obvious bad grammar and logic, characterizes her ideas as simply "the babble of an irresponsible mind."

Commenting upon that portion of the work which refers to medicine, the writer says: "The argument against the employment of medicine for the cure of disease is pathetically naif. 'Which was first, mind or medicine? If mind was first, and self-existent, the mind and not matter must have been the first medicine.' This being so, it follows that mind was the first fire-shovel, and the first load of coals, and the first monkey-on-the-stick that ever appeared in the Lowther Arcade. It is plain, we are told, that God does not employ medicine 'or hygiene,' or provide them for human use, else Jesus would have employed them in His healing. It is also plain that God does not employ the printing-press, or the great Founder of our faith would have used it in the dissemination of His Gospel. If the argument that the use of medicine is in the Christian sense illegal because it was not resorted to in the first year of the Christian era is to be accepted, there is not a great art which has had its growth in the last eighteen centuries which is not equally interdicted from our use and service. There is not a modern product which, in this alarming view of things, is not tabooed to the Christian Science healer's mind. Here is yet another pearl of unreason: 'If drugs are part of God's creation, then drugs cannot be poisonous.' Shall we add to this that if water is part of God's creation, it cannot drown; that if lightning is part of it, it cannot slay; that if an avalanche be part of it, it cannot whelm an Alpine hamlet or carry death and devastation over a populous plain? Mrs. Eddy's argument will not hold water. On the one side she proclaims that God made all things and is All in All, and that all things, therefore, are harmless to His true followers. On the other hand, she enters into a crusade against the use of drugs. The tangled ends of her proposition do not hold together. If drugs are not harmful there is no need of a crusade against them. If God made them they are not harmful. God made everything, and the use of drugs is an appalling mischief."

The fallacies, inconsistencies, and contradictions of the propositions put forward in support of Christian Science are self-evident and must be plain to any person of sense and education. What, then, is the cause of its hold upon individuals of all kinds, ignorant and cultured, for there can be no denying that its tenets are followed by an immense number of people of every state in the United States?

The answer is, according to the writer in *The Referee*, that "it is the foundation upon which the creed is built. That which always has been in the history of mankind is likely always to endure, and there is an insatiable hunger in the human soul for a belief which will lead it outside itself and into the presence of destinies more sublime than are to be sought for in this earthly sphere. However ignorantly that purpose is aimed at by the leaders of the Christian Science movement, the aim itself is manifest to everybody. It does not matter in the least that charlatanism, hypocrisy, and sordid greed are the animating influences of some of its disciples, because there never was a faith, however lofty, which has not been exploited from such motives by ignoble people. . . . There are crowds of people who are making money out of Christian Science, but there is no form of faith whatever, be it religious, political, or social, of which the same thing is not true. If the followers of this latest craze were all of that kidney, there would be no danger in it. Its peril to society lies in the fact that bases itself on the deepest truth of nature, and on that truth builds up its edifice of folly."

The foregoing words are a lucid expression of the causes which have in so short a time pushed Christian Science into a prominent position among the sects of this country. A deep knowledge of human nature doubtless suggested to Mrs. Eddy that by playing upon its weaknesses a mine of wealth might be tapped. If

the high priestess of the new faith is mad, as a perusal of her book might lead one to suppose, there is at any rate "method in her madness." The shrewd commingling of religion and commercialism reveal her not a fanatic but an individual endowed with much judgment of character and a remarkably highly developed business instinct.

This much may be said with respect to the progress of Christian Science in Great Britain: its adherents will not be allowed the latitude they enjoy here, nor will they be permitted to break with impunity the laws of that country regulating the practice of medicine.

RATS AND THE PLAGUE.

At the meeting of the Association of American Physicians, recently held at Washington, bubonic plague was discussed with reference to the outbreak in San Francisco. Dr. Barker, of Chicago, who opened the discussion, in the course of his remarks commented upon the significance of the fact that up to the present there had been no epidemic of the disease among rats in San Francisco. Wherever plague spreads on a wide scale and is of a virulent type, it has been always observed that rats die of the malady in large numbers, and sufficient proof has been undoubtedly afforded that they are among the most potent factors in the dissemination of plague. Koch and Montenegro consider plague primarily a rat disease, and all who have investigated the matter closely agree that these rodents play an exceedingly prominent rôle in the propagation of plague. How the rats spread the disease is quite another question, concerning which there is much difference of opinion, some arguing that the germs of bubonic plague are transmitted to the soil and air through the agency of rats dead and sick with the disease, and thus find easy entrance to the lungs, food, and skin abrasions; there are yet others who believe in contagion and direct infection, while others assert that the disease is communicated to man by suctorial parasites which have bitten the infected vermin, or by flies which have consumed matter in which the plague germs were present. The latter theory would now appear to be gaining ground. Dr. Ashburton Thompson, chief medical officer of health, New South Wales, writes in the April number of the *British Journal of Hygiene* upon the late epidemic in Sydney as follows: "In its mode of spread the plague plainly resembled in some important respects the epizootic tick fever. No theory could be devised, I think, which would co-ordinate the observed facts, unless at all events an animated host, which should not be human, should be discovered for the conveyance of infection. In fact, two such hosts are requisite: one to diffuse the infection, the other to communicate it to man. It is hardly necessary to say what we now believe these two to be; but it is likely that a majority who have not had our practical experience still regard them with the same doubt with which a majority among ourselves regarded them at the beginning of 1900. They are the rat and a suctorial parasite." In short, Dr. Thompson believes with Hankin and Simond that fleas which infest diseased rats are the transmitters of the plague to man.

Nuttall, in 1897, made a series of experiments on flies (Musca domestica), which conclusively proved that flies are able to carry the infection of plague, and that they die of the disease.

Hankin, in 1897, in India killed rats and mice by inoculating them with the excreta of ants (Monomorium vaslator) which had previously devoured rats dead of plague.

Otaga discovered the bacilli of plague in fleas caught upon rats which had died of plague, and is of opinion that such fleas may convey infection by their bites.

The German plague commission in 1897 proved, by inoculating the contents of fleas taken from rats dead of the plague into a guinea-pig, that these fleas contained virulent bacilli.

Simond found that fleas taken from rats and transferred to human subjects proceed to suck the blood of the latter. This is an important point, as it is denied by many that rat fleas will bite man. He further found bacilli in fleas taken from rats dead of plague, which presented the microscopical appearance of plague bacilli. He therefore, as a result of his investigations, reaches the following conclusion: "That the different forms of so-called spontaneous plague in man and animals are usually to be attributed to parasites," and he thinks that this theory explains the prevalence of plague especially in filthy localities.

Nuttall criticises Simond's views as hypothetical and inconclusive, and wisely remarks that more facts and fewer opinions are needed, and that the facts can be gathered only by further experimental research. His own experiments with fleas and bugs were negative.

The question, then, as to the manner in which the plague is conveyed from rat to man cannot as yet be said to have been definitely decided. Flies may, and probably do, transmit the disease, and Simond's parasitic theory of conveyance has many strong points in its favor. This much, however, is undeniably true—that rats are in themselves a danger to the world at large as propagators of the plague, and it would also seem that to them is due the widespread nature of the pestilence and its occurrence in out-of-the-way places.

A wholesale massacre of rats with the means now at hand is impossible, even if such a slaughter were desirable; but by putting into force every possible method for their destruction in those places where plague exists, and by taking rigid precautions to prevent their ingress from ships from infected ports into countries with a clean bill of health, the spread of the disease will be considerably checked. Quarantine is practically useless against the infection—that is, unless the ships themselves are debarred from mooring at the quays. Such a course, it has been suggested, might be followed in the case of suspected vessels.

The most effectual measure in fighting the plague is, after all, cleanliness. Rats flourish chiefly in places where sanitary conditions are bad, and cannot exist where these conditions are good. The truth of this assertion has been demonstrated many times and

in many places. Human neglect is responsible for the multiplication of rats, and this fault can be best remedied by paying strict attention to the laws of hygiene.

THE COMMITTEE OF SEVEN AND PROSTITUTION IN NEW YORK.

In February last the President of the Medical Society of the County of New York, in pursuance of a resolution, appointed a committee to study the question of prostitution in this city in its bearings upon the morbidity and mortality from venereal diseases. This committee, composed of well-known, earnest physicians, has just issued a circular letter addressed to the practitioners of Greater New York, asking their co-operation in collecting statistics upon the prevalence and seeking the views of individuals as to the increase or decrease of these diseases, and the measures best adapted to limit or prevent their dissemination. A movement of this kind, having the prophylaxis of disease as its aim, can count upon the support of the entire medical profession, and the Medical Record desires, in giving its approval, to urge upon all to whom the circular has come the duty of answering, so far as it is possible, the questions bearing upon the vast amount of misery which comes into the doctor's field of vision, which has to do with venery in only a remote way.

Some one has recently written upon non-licentious lues. The term applies with equal force to the many forms in which gonorrhœal affections are thrust upon the guiltless. Some years ago statistics were collected showing the prevalence of ophthalmia in infancy and childhood, due to this cause, and the blindness resulting from it, and the figures were startling. Since then much has doubtless been accomplished in diminishing the number and severity of this class of cases. Vulvovaginitis in youthful subjects has of late years attracted much attention from its marked prevalence in certain quarters, and has been the cause of no little trouble in a number of institutions.

All gynæcologists know only too well what a large percentage of their pelvic cases has an origin directly traceable to innocent infection of this kind. According to some writers family lues is becoming more frequent, and the instances of the disease, innocently acquired, seem at times almost to outnumber the others in the practice of some physicians. There is therefore no longer any place for prudery in approaching so vast a question and one so important to the community at large. Those institutions whose lay boards of managers will not permit the diagnosis of these diseases to appear upon their record books or to be printed in their reports, for fear of offending the sensibilities of delicate and refined persons who might otherwise not contribute to the institutions' support, must awaken to the knowledge that the greatest aim of hospitals and dispensaries is to keep the people well and prevent dissemination of disease of all kinds.

It is earnestly to be hoped that every physician will contribute his mite in so worthy a cause, and if any one hesitates for personal reasons about letting the committee know how many or few cases he may have had the fortune or misfortune to observe during the year he can omit his signature in sending in the returns.

News of the Week.

Syphilis in the Well-to-Do. — The article by this title, published in the Medical Record of May 11th, was in some unaccountable way printed as from the pen of Dr. J. E. McDonald. The author of the paper was Dr. R. A. McDonnell, of New Haven, Conn.

The American Congress of Tuberculosis held its second annual meeting at the Hotel Majestic in this city last week, under the presidency of Mr. Clark Bell. The question of sanatoria was thoroughly discussed, and the proceedings were enlivened by some hard words against present-day medical science embodied in a paper by a former anti-imperialist, who has gradually raised his anti until it applies to everything except himself.

The University of Pennsylvania is about to erect, at a cost of more than $500,000, exclusive of grounds and equipment, a medical laboratory building. It will be quadrangular in shape and will be located on the south side of Hamilton Walk, between Thirty-sixth and Thirty-seventh streets. The building will be two stories in height above a high basement, and will measure three hundred and forty feet front by near two hundred feet in depth. All along the front are arranged small rooms for research, rooms for professors and their assistants, a library, etc.; these open into a private corridor, so that men employed in these rooms may pursue their work without interruption from students passing through the main halls. Perfect lighting of all the laboratories has been obtained, the courts being large enough, with the low front building, to furnish good north light to the laboratory of pharmacy and pharmacodynamics on the first floor, and to the laboratories on the second floor devoted to pathology, the north front of these rooms facing on the courtyard being made almost wholly of glass and extending higher than the front, so that steady north light will be thrown to the back of the room.

The Prevention of Malaria on a Large Scale.— It is stated in the *British Medical Journal* that Major Ronald Ross is about to carry out a gigantic experiment on the connection between malaria and mosquitos by endeavoring to rid an infested neighborhood of the offending insects. Some large town in which malaria is prevalent is to be chosen, and steps will be taken to fill up or otherwise abolish all pools and puddles which can serve as breeding-grounds for Anopheles, and these precautions will be maintained for a period of twelve months. The town which is to be the subject of the experiment has not yet been decided upon, but Major Ross is preparing to start for the tropics in a few weeks in order to direct operations. An experiment on so large a scale will evidently re-

quire the co-operation of a large number of skilled and intelligent assistants, and cannot be carried out without great expense. The expense has, in fact, hitherto been the chief obstacle in the way of such experiments, but in this instance the cost has been generously guaranteed by a private individual, who for the present desires his name to be withheld from publication.

A State Sanatorium for Tuberculosis in Minnesota.—The Minnesota legislature has appointed a commission to investigate and report concerning the advisability of establishing a State sanatorium for the care and treatment of indigent consumptives.

The Plague is reported to be decreasing at Cape Town, only one case having been reported in the three days ending May 19th. The total number of cases to that date has been six hundred and thirty-nine, two hundred and ninety-two of which terminated in death.

No Compulsory Vaccination in Wisconsin.—Governor La Follette, of Wisconsin, recently vetoed the Collins compulsory vaccination bill. In giving the reasons for his veto, the governor said he did not believe that an emergency existed demanding such a law, which he characterized as repugnant to many good citizens.

Stony Wolde Sanatorium.—At a meeting of the incorporators and directors of this sanatorium, held last week, under the presidency of Mr. Frederick B. Jennings of the advisory board, the following were elected officers of the institution for the ensuing year: *President*, Mrs. James Edward Newcomb; *Vice-Presidents*, Mrs. George F. Shrady, Mrs. H. Walter Webb, Miss Virginia Potter, Mrs. Anson R. Flower; *Recording Secretary*, Mrs. John Caldwell Coleman; *Corresponding Secretary*, Mrs. William Hubert Burr; *Treasurer*, Mrs. Edgar L. Marston; *Assistant Treasurer*, Mrs. Herbert L. Satterlee. The institution will be for the care and treatment of working girls, young married women, and children suffering from incipient tuberculosis, and will be situated at Kushaqua, Franklin county, this State. A tract of land comprising twelve hundred and fifty acres has been secured, and it is hoped that work on the buildings will be begun by July 1st. It will be necessary to have $50,000 in hand on that date; of that sum $36,000 is now in the treasury.

The New York State Hospital for the Care of Crippled and Deformed Children was formally opened at Tarrytown on May 18th. Bishop Potter, the president of the board of managers of the institution, presided and made the opening speech. A special train took about three hundred persons to the Tarrytown station, whence they were taken in stages to the new institution, situated on Paulding Avenue, overlooking the Hudson. The opening exercises were held in a tent on the large lawn which surrounds the hospital building. Dr. Robert F. Weir, of Columbia University, A. Alexander Smith, of the University of the City of New York, and William M. Polk, of Cornell University, and Mr. William Rhinelander Stewart also made brief addresses. Aside from Bishop Potter, the board of managers consists of J. Hampden Robb, J. Adriance Bush, George Blagden, Jr., and Dr. Newton M. Schaffer. There are at present eighteen patients in the institution.

Smallpox in a Convent.—Fifteen cases of smallpox were discovered last week in St. Francis' (Polish) Convent, Detroit, and the entire institution has been quarantined by the board of health. There are one hundred children and thirty nuns in the convent. The victims have the disease in a mild form, and no deaths are expected.

A Loss to Tropical Medicine has been sustained by the death of Dr. Paul Kohlstock, which, as we have previously noted, occurred at Tien-Tsin on April 15th. He was born in Berlin in 1861, and received his medical education at the Friedrich-Wilhelm University. Entering the medical service of the German army in 1887, he was in the following year sent to East Africa, where he worked under Wissmann. In 1890 he became staff surgeon, and as such served as assistant in the third medical clinic of the Charité, Berlin. A year later he was appointed lecturer on tropical hygiene in the Oriental Seminary. In 1896 he accompanied Koch to Cape Colony for the investigation of cattle plague. His contributions to medical literature were mainly concerned with tropical hygiene, and especially with malaria, and although only forty years old he had won for himself an enviable position as an authority on all subjects relating to tropical medicine.

Damages Claimed for an Incorrect Diagnosis.—A claim for damages on somewhat curious lines is now being heard by the Paris courts. A young man, the manager of a warehouse, was taken suddenly ill at the house of his fiancée. The family doctor of her parents was called in, and diagnosed the case as tuberculosis, persuading the young man to undergo an operation. Then the doctor informed the parents of the fiancée that the young man was suffering from consumption, whereupon the marriage was broken off. On consulting his own doctor, the opinion of the other medical man was controverted, and upon expert evidence being taken it was found that there were no signs of consumption, while the operation performed was absolutely unnecessary. Wherefore the young man is suing for damages for "unnecessary mutilation" and for loss consequent upon the change in his matrimonial prospects.—*Medical Times and Hospital Gazette.*

Smallpox Throughout the Country.—Some statistics recently collected by Dr. Dillingham, of the New York City health department, regarding the prevalence of smallpox in the different States of the Union, show that this city is by no means peculiar in its suffering from this disease. He finds that during the eighteen weeks from December 28, 1900, to May 3, 1901, there was a total of 22,344 cases of smallpox reported in the United States. Of this number there were in New York City only 723 cases, while there were in Kansas, 3,915; Colorado, 1,763; Minnesota, 2,753; North Carolina, 723; Ohio, 1,685; Tennessee, 4,228; Utah, 724; Alabama, 45; California, 64;

Connecticut, 9; Delaware, 57; Iowa, 26; District of Columbia, 51; Florida, 113; Georgia, 22; Idaho, 10; Illinois, 354; Indiana, 557; Indian Territory, 216; Kentucky, 59; Louisiana, 206; Maine, 1; Maryland, 26; Massachusetts, 15; Michigan, 55; Mississippi, 4; Missouri, 215; Montana, 218; Nebraska, 654; Nevada, 1; New Jersey, 46; New Hampshire, 334; New Mexico, 4; North Dakota, 66; Oklahoma, 690; Oregon, 10; Pennsylvania, 221; Rhode Island, 10; South Carolina, 10; Texas, 486; Virginia, 328; Washington, 38; West Virginia, 66; Wisconsin, 575, and Wyoming, 4.

New York Medical Society for Clinical Research.—At the meeting of this society held Monday, May 20th, there was a discussion on "Infantile Diarrhœa," papers being read by Drs. Heller and Lubman.

The American Dermatological Association.—The twenty-fifth annual meeting of this society will be held at the Beach Hotel, Chicago, on May 30 and 31 and June 1, 1901, under the presidency of Dr. Francis John Shepherd, of Montreal. The secretary is Dr. Frank Hugh Montgomery, of Chicago.

Garbage Cremation on Barren Island.—The supreme court has declared unconstitutional the law passed a year ago forbidding the burning of the city garbage at the crematory on Barren Island, and accordingly such disposal of it may now be resumed. The Barren Island site was selected by the late Colonel Waring as the most appropriate place, and a private company erected a plant there at a cost of about half a million dollars.

Exhibit of the United States Army Medical Department at Buffalo.—Dr. Edward L. Munson, captain and surgeon U.S.A., has been placed in charge of the exhibit of the medical department of the army at the Pan-American Exposition at Buffalo. The exhibit consists of a model field hospital, and under Captain Munson's command is a detachment of thirty soldiers, who give daily demonstrations of transportation of wounded, first aid on the firing line, field surgery, and the establishment and management of field hospitals.

The American Gastro-Enterological Association held its fourth annual meeting in Washington on Wednesday, May 1st, the sessions being very appropriately held in the banquet hall of the Shoreham Hotel. The following papers were read: "Syphilis of the Liver," by Dr. Max Einhorn; "The German Clinics of Today," by Dr. J. C. Hemmeter; "Some Cases of Tetany," by Dr. William Gerry Morgan; "The Report of Two Cases of Acute Dilatation of the Stomach," by Dr. Julius Friedenwald; "Treatment of Atonia Gastrica and Splanchnoptosis by means of Abdominal Strapping," by Dr. A. Rose; "Hyperchlorhydria," by Dr. John A. Lighty; "Report of a Case of Cancer of the Cardiac End of the Œsophagus at a Distance of Twenty-one Inches from the Incisor Teeth in a Man Five Feet and Three Inches Tall," by Dr. C. D. Spivak; "Spastic Ileus," by Dr. Edward Quintard. The following officers were elected: *President*, John C. Hemmeter, of Baltimore; *First Vice-President*, Dr. W. D. Booker, of Baltimore; *Second Vice-President*, Dr. S. J. Meltzer, of New York; *Secretary and Treasurer*, Dr. Charles D. Aaron, of Detroit; *Councillors*, Drs. Max Einhorn, of New York, D. D. Stewart, of Philadelphia, and A. L. Benedict, of Buffalo. The next meeting will be held in Washington on Thursday, May 1, 1902.

Fighting Mosquitos.—A number of village and town improvement associations in New Jersey have appointed "mosquito extermination committees" whose function is sufficiently denoted in the title. The Summit committee has recently gone to work most energetically. All the ponds and swamp holes in the town and its neighborhood have been covered with kerosene oil in the hope of effecting the eradication of mosquitos. In about a month the ponds will receive a second treatment.

College of Physicians of Philadelphia, Section on General Medicine.—At a stated meeting held May 13th, Dr. F. A. Packard exhibited "A Case Simulating Carotid Aneurism." The patient was an elderly colored woman with extreme tortuosity of all of the superficial vessels and a distinct doubling over of the left carotid artery forming a visible and palpable loop. Dr. Packard exhibited also "A Case of Pernicious Anæmia with Peculiar Pigmentation of the Skin." The patient was an emaciated car conductor of middle age, who, together with marked pallor and extreme reduction in the number of red blood corpuscles and also in the percentage of hæmoglobin, presented a muddy brown hue of the skin in the midst of which were areas of wholly unpigmented white skin. The opinion was expressed that the cutaneous disorder was vitiligo, but none could be formed as to whether it bore any relation to the blood disorder or not. The anæmia, it was thought, was possibly due to atrophy of the gastric tubules. Transitory improvement followed the administration of Fowler's solution of potassium arsenite in conjunction with Basham's mixture of iron and ammonium acetate. Dr. William G. Spiller reported "A Case of Paralysis of the Median Nerve Following a Bullet Wound of the Arm." An operation had been performed early in the history of the case, and the median nerve found swollen and apparently injured, and the question was raised whether under such circumstances it might not be justifiable to excise the injured portion of nerve and unite healthy portions. Dr. D. J. McCarthy exhibited "A Case of Amyotrophic Lateral Sclerosis of Unilateral Type, with Bulbar Involvement." In addition to muscular atrophy and increased reflexes upon one side of the body, the patient presented a typical claw hand, while speech was scarcely intelligible. Dr. McCarthy exhibited also "A Case Showing Increase of the Supraorbital Reflex." The reflex is elicited by tapping the forehead in the distribution of the supraorbital nerve, and consists in fibrillary twitching of the orbicularis palpebrarum on the corresponding and sometimes also upon the opposite side. It is excited through the arc constituted by the fifth nerve on the one hand and the seventh nerve on the other, being abolished as a result of paralytic disease, and increased as a result of irritative disease. A case presenting the latter peculiar-

ity was demonstrated. Dr. Joseph Sailer read a paper entitled "The Use of Gelatin for the Arrest of Hemorrhage," in which he traced the evolution of this practice and analyzed the results reported. He related cases of aneurism, of gastric ulcer, of typhoid fever, of metrorrhagia, in which it appeared to do good. It may be administered by the mouth or by subcutaneous injection in from two- to ten-per-cent. sodium-chloride solution in amounts of from 200 to 10 c.c. Dr. Sailer read also a paper entitled "A Clinical Contribution to the Clinical Manifestations of Exophthalmic Goitre," in which he spoke especially of the employment of sodium phosphate in treatment, confirming the results reported by foreign observers. Dr. D. D. Stewart reported "A Case of Leukæmia," in which there were at first symptoms suggestive of scurvy, but subsequently fever and other manifestations that raised the suspicion of typhoid fever developed, and now the blood, which had previously exhibited no histological alteration, presented the features of leukæmia. The presence of the Widal serum reaction was reported as a result of a single examination of the blood. On post-mortem examination, in addition to other alterations, a number of ulcers were found in the colon, and a decision had not been reached as to whether these were leukæmic or typhoid. Dr. Stewart made also a brief report of "A Case of Splenic Abscess."

The Loomis Laboratory and the New York University.—The litigation between the New York University, the Medical College Laboratory, and the Loomis Laboratory ended last week with decisions by Justice Truax of the supreme court against the university. By the decision in the suit brought by the Medical College Laboratory the medical school property in East Twenty-sixth Street, including its contents, valued at $150,000, is to be transferred by the New York University back to the Medical College Laboratory corporation, and until this transfer the university is prohibited from using the property. By the decision in the case of the New York University against the Loomis Laboratory it is held that the Loomis Laboratory in East Twenty-sixth Street, which is now allied with Cornell University, is not held in trust by the Loomis Laboratory for the New York University.

Pennsylvania Hospital.—The one hundred and fiftieth anniversary of the establishment of the Pennsylvania Hospital was celebrated on May 11th with appropriate ceremonies.

Faith Curist Fined.—Judge Smith Lent, in the Westchester County court at White Plains yesterday, sentenced J. Luther Pierson, of Valhalla, a faith curist, who was convicted on Tuesday of violating the law by neglecting to call in a doctor for his two-year-old daughter, who was ill with pneumonia, to pay a fine of $500.

For All Creeds and Races—Cornerstone of Mount Sinai Hospital Laid.—Several thousand persons, on the afternoon of May 21st, saw the ceremonies attending the laying of the cornerstone of the new Mount Sinai Hospital, which will occupy the block bounded by Fifth and Madison avenues, and One Hundredth and One Hundred and First streets. Governor Odell, who was expected to make an address, was kept away by the illness of his daughter. The first address was made by Randolph Guggenheimer, president of the council, who represented the mayor. President Seth Low, of Columbia University, who was the next speaker, alluded to the growth of the hospital and its needs for larger buildings and better facilities, and in regard to the broad principles which had been followed in the founding of the hospital he said: "It has always been true that sympathy with suffering is not confined to any race or to any people; but it has not always been true that men of different races and of different creeds could so respect each other's views and honor each other's work as to make possible an occasion like this. I count it not the least of the services which our hospitals have rendered to this community that not one of them asks, when a sick person is brought to its doors, whether he is a Jew or Gentile, Protestant or Catholic." The cornerstone, to which a bronze tablet was fastened and in a chamber of which had been placed a written history of the hospital and other documents, was swung into place, covered with American Beauty roses. Isaac Wallach, president of the Mount Sinai Hospital, received from Isaac Stern, chairman of the building committee, a silver trowel which he used in spreading some of the mortar as the stone was lowered to its resting-place. He said: "We dedicate this building to the glory of God; we consecrate it to the service of man. We rear it for the distressed and suffering of all creeds and nationalities. May it raise its head high to proclaim the doctrine of universal brotherhood; may it stand for ages to cheer and comfort the weary, weatherbeaten traveller in his pilgrimage through life; may it transmit to future generations a message of good will and the epitome of our true understanding of that which is broad, progressive, and uplifting." Closing addresses were made by Edward Lauterbach and by Dr. A. Jacobi, president of the medical board of the hospital.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending May 18, 1901. Medical Director J. C. Wise appointed member of examining-board, Annapolis, Md., for examination of candidates for cadets. Passed Assistant W. B. Grove, orders as member of examining-board, Naval Academy, revoked. Surgeon C. Biddle detached from navy yard, Philadelphia, and ordered to the *Indiana*. Surgeon O. Diehl detached from the *Indiana*, and ordered to the Philadelphia navy yard.

Philadelphia County Medical Society.—At a stated meeting held May 8th, Dr. Simon Baruch, of New York, read by invitation a paper entitled "Lessons of a Decade in Hydrotherapy." He stated that water is a medium through which temperature effects upon the body can be produced, not alone upon the surface but also upon the interior, the result varying with the difference between the temperature of the body and that of the water applied, and differing also as the one is higher or lower than the other, as well as with the manner and the duration of application. The appli-

cation of cold to the surface is stimulating, that of warmth sedative. The former causes contraction of peripheral vessels, with increased arterial tension and an increased supply of blood to the internal viscera; the latter dilatation of peripheral vessels, lowered arterial tension, and a diminished supply of blood to the internal viscera. There can be no doubt that the nervous system, apart from the vessels, also is affected, and an influence is exerted upon respiration and the general metabolism. Extremes of heat and cold may be paralyzing of function to the point of destruction. The effects of hydrotherapy differ also accordingly as friction is employed and as the water is applied in the form of bath, of pack, of douche or spray. Hydriatic procedures are useful in the treatment of acute febrile diseases not so much on account of their antithermic or antipyretic effects, but rather for their vivifying influence upon the peripheral and central nervous apparatus. They are susceptible of scarcely less useful application in the treatment of chronic diseases, especially those of a functional character with manifestations of nervous derangement, improving appetite, strengthening digestion, aiding assimilation and absorption, maintaining nutrition and metabolism, promoting sleep, and stimulating function generally. Dr. Baruch made a special plea for a proper selection of means to ends, for precision in dosage, and for persistence in treatment. To this end he maintained that courses of instruction in the subject of hydrotherapy should be given in the medical colleges in order that physicians may be able to employ intelligently and successfully a most powerful and useful therapeutic agency. Dr. Wharton Sinkler read a paper entitled "The Effects of the Douche in Neurasthenia and Other Nervous Troubles," in which he dwelt upon the utility of hydrotherapeutic procedures in cases in which other treatment is inapplicable or had been employed and failed. One case in particular was related in which insomnia that had proved rebellious to many agents, including hydrotherapy in the hands of many men, had finally yielded to a systematic course of hydriatic treatment. Dr. S. Solis-Cohen stated that he had for a number of years lectured to undergraduate students on hydrotherapy, and he expressed the opinion that every large city should be provided with a hydriatic establishment to which patients could be referred by any physician and receive the treatment best adapted to their individual needs. Dr. J. H. Musser also spoke, and a brief communication on the subject from Dr. James M. Anders was read. Dr. Robert G. Le Conte read a paper entitled "The Value of the Combined Medical and Surgical Clinic to the Student," in which he related a plan that in conjunction with Dr. F. A. Packard he had followed in part at the Pennsylvania Hospital. There are a number of diseases, such as pulmonary gangrene, pulmonary abscess, tuberculous cavities in the lungs, hydatid disease of various organs, appendicitis, gastric ulcer, typhoid perforation, malignant disease in one situation or another, accumulations of fluid in serous cavities, brain abscess, brain tumor, and others, that may require either surgical or medical treatment at one time or another in their course, and that therefore may with advantage be studied conjointly by physician and surgeon, both in actual practice or in teaching. In the clinical course referred to, the medical clinician would consider the various medical aspects of the case —etiology, pathology, diagnosis, prognosis, treatment —after which the surgeon would consider the operative aspects, and if necessary undertake the necessary procedures. At subsequent clinics the progress of the cases would be followed, and in the event of death the specimens would be exhibited. The course had proved most popular and successful, as well as most useful and instructive, both to students and lecturers.

Obituary Notes.—Dr. Andrew K. Minich died at Philadelphia on May 11th, at the age of fifty-four years. He was a graduate of Lafayette College and in 1870 from Jefferson Medical College. He enlisted as a surgeon in the German army during the Franco-Prussian war, and on his return to this country became a lecturer in the Wagner Institute of Science and also in Jefferson Medical College. He was for more than twenty years one of the physicians to the Episcopal Hospital.

Dr. John A. Wells, aged forty-five years, died of pneumonia on Tuesday, May 21st, at his home in Englewood, N. J. He was one of the leading physicians in his town and was the house surgeon of Englewood Hospital.

Dr. Robert Bolling died on May 12th at Chestnut Hill, Philadelphia, at the age of sixty-eight years. He was a graduate of the University of Virginia and in 1855 from the medical department of the University of Pennsylvania. After graduation he became a resident physician in St. Joseph's Hospital, subsequently spending several years abroad in study. On his return he became demonstrator in the Philadelphia School of Anatomy. During the Civil War Dr. Bolling was assistant executive officer at "The Mower" United States Army Hospital. He was president of the Pennsylvania Alumni of the University of Virginia.

Progress of Medical Science.

New York Medical Journal, May 18, 1901.

Relations of Vascular Disease to Heart Disease.—By W. H. Thomson. So far as the factor of intravascular strain is concerned in producing vascular disease, the original cause is to be located in unfavorable conditions within that area of the circulation which ministers directly to nutrition, that is, the capillaries. These in turn are affected by the various poisons as lead, gout, alcohol, intestinal ptomains, kidney disease, and syphilis. We are not yet able to explain the selective action of these various poisons—not able to tell why lead, for instance, attacks the extensors rather than the flexors, but no poison is more selective than syphilis when it causes vascular disease. Its preference is for the arteries as the base of the brain, and the carotids and at the Sylvian fissure, while the arteries of the hemispheres escape. The coexistence of vascular disease may alter the conditions of the problems of heart disease. Hence, recognizing that the heart is only one part of the circulatory apparatus and simply shares in a general diseased condition, we must make a careful study of each case, basing our remedies on not only the result of our physical examination of the patient, but on his physical inheritance and his mode of life.

The Use of the Suprarenal Capsule in Diseases of the Heart.—S. Floersheim summarizes the clinical histories of a large number of cases, and concludes as follows concerning the various therapeutic effects observed: (1) A weak and irregular-acting heart became stronger and more regular. (2) A dilated heart was contracted. (3) A diffused

apex beat became localized. (4) A diffused, loud, and rough mitral regurgitant murmur became localized, smoother, and lessened in intensity, while in some cases the murmur disappeared. (5) A murmur which, owing to the extreme weakness of the heart, could scarcely be heard, became more distinct, thus aiding in the diagnosis. (6) The normal cardiac sounds, when indistinct, became clearer and more easily distinguished. (7) In some cases a rapid pulse became less rapid; in other cases a slow pulse became faster. (8) Patients who were very weak, with organic heart disease, were improved. (9) No effect was observed in organic heart disease when the pulse was strong and regular.

Air a Factor in Digestion.—E. W. Moore considers that the final step in digestion occurs in the lungs in the shape of the elimination of carbonic acid and the oxygenation of the venous blood plus the new products from the food received through the chyle. Hence, an additional chemical element is necessary, and that element is oxygen. Oxygenation is therefore a part of the digestive process because, from the time food has entered the mouth, the circuit has not been changed, barring the absorption of water and the salines, until the systemic circulation has become a factor, because the pulmonic circulation affords the first time at which oxygen is added to the sum of the elements, because all oxygen furnished to the system prior to this is abstracted from, not added to, the sum of the elements after ingestion, and because there is a lung digestion as surely as a stomachic or intestinal digestion.

The Proper Administration of the Schott Exercises.—By Victor Neesen.

Journal of the American Medical Ass'n, May 18, 1901.

The Ocular Expression of Intranasal Lesions.—By R. Sattler. Two classes only of intranasal lesions are considered. The first group includes certain chronic lesions which invade the anterior region of the middle meatus of the nose—the most anterior cells of the ethmoidal labyrinth—bulla ethmoidalis, the region of the uncinate process, hiatus semilunaris, and infundibulum. Two principal clinical expressions of lesions of this region of the nose on the part of the eyes are met with: (1) Persistent injection of the vessels of the ocular conjunctivæ with prominence and distention also of the muscular branches, often accompanied by passive œdema of the retrotarsal folds. The palpebral conjunctiva does not ordinarily participate in this vascular engorgement. Not infrequently there is observed a retraction of the upper lid and that peculiar stare which is so generally associated with a retarded lid action due to disordered innervation of the sympathetic fibres. In the second class of cases the clinical expression is in the form of most persistent neuralgic phenomena, not conspicuous because of their severity, but mainly for their persistent nagging features, and associated with the most distressing functional disturbances of the eyes. The second class of intranasal lesions refers to cases better understood and unmistakable so far as the diagnosis and general character of the nasal and ocular lesions are concerned. There is invariably present in these cases a focal suppuration in the nose—of the inferior meatus, inferior turbinate—or of the adjacent cells of the ethmoid and frequently of the maxillary sinus. The nasal lesion, however, because of the dominant ocular symptoms, does not receive adequate attention. The cases referred to are those which are considered the most unmanageable of tear-sac and nasal-duct lesions. Chronic suppuration with fistulæ of the tear sac and granular degeneration of its mucous linings are present, together with thickening of its walls, vicious bone ulceration and sequestration on the part of the osseous portion of the nasal duct, focal suppuration of the inferior meatus of the nose, ethmoidal labyriuth, maxillary sinus, etc. These are the cases in which the radical extirpation of the tear sac by cauterization or excision, with or without removal of the lacrymal gland, is necessary.

A Study of the Etiology and Pathology of Rheumatism with Special Reference to "Rheumatic Diathesis."—By A. P. Stoner. The author's study leads him to conclude: (1) That rheumatism is directly due to an infectious germ, and that the symptoms produced vary in accordance with the position and attenuation of these germs; (2) that these germs may at times complicate other disease conditions, as, for instance, scarlet fever, thereby causing rheumatic symptoms; (3) that the nidus of the germs may be located in the joints, which is usually the case, especially in adults, or more rarely in the heart, and quite frequently in the muscles; (4) that the uric and lactic acids found in these cases are products, rather than the cause, of the disease, and that, of themselves, their presence is not pathognomonic of gout and rheumatism, in that they simply show the result of katabolism of the body cells, which condition may be brought on by numerous nutritional disorders; (5) that hereditary tendency, if carefully sought out, may be found in a large majority of cases; (6) that gout and rheumatism, although very dissimilar diseases, each possesses so many traits in common that we have been led to place them in the same family of diatheses. Both produce the same end products of tissue metamorphosis, their nidi of infection have much the same location, and the pathological conditions found therein are closely related. There is a tendency to cutaneous disorders in both diseases.

The Reduction of Temperature in Fevers by Evaporation Baths; Warm Water Being Used for Baths.—By F. H. Williams. The method of giving the baths is thus described: Give a bath whenever the temperature is 102° or 102.5° F. Have the patient lie on a blanket during the bath; cover him with one thickness of surgeon's gauze, which, when moistened, shall fit the skin perfectly, and sprinkle the gauze with water at about 115° F. Note the amount of water evaporated, and be guided by this in giving the bath, not by the time required to evaporate the water; the rapidity of evaporation depends largely on the amount of moisture in the air. Have as little clothing on the patient as possible, night and day, so long as the temperature is 102° F. or more, nothing more than a sheet; in private practice the patient may be without covering. Judging from results given, the method appears to be reliable and efficient. It is often applicable when the full tub bath is for various reasons impossible. Evaporation can be hastened by fanning.

Infantile Scorbutus.—John Lovett Morse writes that while the more marked cases are now usually recognized, the milder cases are often overlooked and misunderstood. The disease usually occurs between six months and two years of age. The earliest symptoms are probably anæmia and malnutrition. The first, as well as most persistent and constant symptom, is pain, which increases steadily in severity, and usually occurs in the legs, back, and arms. Paralysis is often suspected, as the patient dreads to move the extremities for fear of increasing the pain. Swellings begin to appear, more commonly in the thighs, and are due to subperiosteal hemorrhage. Swelling, sponginess, and ulceration of the gums, hemorrhages in various parts and tissues of the body, anæmia, and occasional fever are the ordinary symptoms. The majority of cases arise in babies fed on proprietary foods; in some instances, however, it occurs when the child has been fed on breast or cow's milk. The treatment consists of regulation of the diet and the administration of orange or lemon juice.

A Case of Accidental Inoculation of Cancer in a Fresh Wound.—A. J. Cabot reports the case of a man aged fifty-nine years with a cancer high up on the anterior wall of the rectum. An opening was made through a Kraske incision into the rectum posteriorly and the cancer removed. During the manipulation the growth was rubbed about in close contact with the wound made by the Kraske operation. The patient remained well for two years, when a hardening of the tissues behind the rectum was noticed. This was found to be an adenocarcinoma like the first. The scar in which the recurrence took place was separated by an interval of five or six inches from the original seat of the growth, the tissues between having remained healthy. The lymphatic vessels from the seat of the original disease ran upward to the lumbar glands. This anatomical relation, together with the absence of any

lymphatic structure in the recurrent nodule, removed any suspicions of this having been a second growth in a gland.

Neuritis Recurring after Atrophy of Both Optic Nerves in a Case of Brain Tumor.—Edward R. Williams reports a case in which among other symptoms there are three points worthy of notice: (1) Recurring neuritis following the atrophy of each disc; (2) the similarity in appearance between neuro-retinitis caused by brain tumor and a chronic nephritis; and (3) the mildness and indefiniteness of all the symptoms, both ocular and general, as compared with the amount of change in the brain. A large part of the corpus callosum was totally destroyed, and the apex of the new growth appeared in the interpeduncular space, where it compressed the second and third cranial nerves. The only effect on the third nerve was to irritate it sufficiently to cause a temporary dilatation of the left pupil. There was no paralysis of the eye muscles.

The Treatment of Psoas Abscess by Incision.—By Robert W. Lovett.

American Medicine, May 18, 1901.

A Plea for Uniformity of Technique in Widal's Reaction.—Randle C. Rosenberger urges that the following points be adopted in order to attain uniformity of technique in Widal's reaction: (1) The use of a uniform dilution. (2) A definite time-limit. (3) An agreement as to what constitutes a positive reaction. (4) The use of a culture of definite age, and a clear statement as to incubation or non-incubation. (5) A decision as to whether dried blood, fresh blood, or serum is to be used. (6) A stated number of tests to be made in a given case. (7) To drop the terms "doubtful" and "pseudo" reaction. (8) Use of terms "positive" and "negative" only. The author adds that he is merely pleading for uniformity in this method—not for the revolution of it.

Gastric Tetany, with Report of Cases.—William Gerry Morgan gives this interesting communication: One of the cases reported was that of a man aged forty years, well-nourished and muscular; he was of nervous temperament but cheerful disposition. He had suffered from slight attacks of dyspepsia for more than ten years. At times he had spells of dizziness whenever worried or hurried after a hearty meal. Seven years ago he had an attack which he calls "a fit." After being startled by sudden news he became unconscious; when he regained consciousness his arms were so sore and stiff that he could not use them for several hours, and he was nauseated. These attacks increased in frequency till a few months ago, when he was having two or three a week. In some of the attacks he does not lose consciousness, though he suffers from vertigo. These attacks always begin with the vomiting of very acid liquid, with or without admixture of food. The attacks in which he loses consciousness are not preceded by vomiting, but are usually followed by both nausea and vomiting. During attacks when consciousness is lost the hands and forearms are flexed and rotated inward; the fingers and thumbs are flexed and claw-like, and in the beginning there are muscular twitchings which gradually become quiet, although the contractures continue. The head is rotated more or less to the right side. The tongue is not protruded. The treatment in this case consisted of a suitable diet, with small frequent meals; teaspoonful doses of sodium bicarbonate an hour after meals, to be repeated in an hour if the pyrosis is not relieved; bromide of strontium in five-grain doses before meals. Since five weeks after beginning this treatment he has had only two attacks—both the result of overeating.

An Exceedingly Rare Case of Imperforate Anus.—Charles B. Kelsey reports the following case: The patient, a man aged twenty-four years, was born with an imperforate anus. Within a few days after birth an opening was made in the perineum, and there has always been a free communication between the bladder and the rectum by which urine escaped per rectum and fæces per urethram. He has frequently gone for three months without any fecal evacuation of any sort, at the end of which time the amount of fecal matter passed at one time is very great. There is a deep anal depression ending in an undilatable slit, through which the examining finger encounters an immense fecal impaction of stony hardness. There is no sphincter. It took two men and two nurses, with the patient under ether, forty-five minutes to break up and wash out this fecal mass. There is no corpus spongiosum for about an inch and a half in front of the triangular ligament. Its place is taken by a thin membrane separating the urethra from the rectum. Communication with the rectum existed for a space about one-third of an inch in diameter, at which point the membrane is absent. The incision for colostomy was made and no descending colon was found at the usual site, but instead an immense muscular pouch which felt like an enormous stomach. At the point which would ordinarily mark the end of the transverse and beginning of the descending colon an artificial anus was established with the usual spur, under the gut, through the mesentery. There were other congenital defects in this patient, such as absence of development of the muscles of the left thumb, and almost complete absence of both radial arteries.

The Functional Tests of Hearing.—William Lincoln Ballenger reviews various tests in use for the testing of hearing. The watch test has long been used to test the acuteness of hearing and is of more or less value. It is also used to ascertain the tonicity of the stapedius muscle. In the voice test, Oscar Wolf found the letter R to be the lowest in the scale, while S is the highest. He found speech to be confined within about six and one-half octaves. The greatest strength and timbre belong to the vowel A, and the smallest to the consonant H. The most valuable physiological tests are those made with the tuning-forks and whistles. The test outfit for making a complete test of the range of hearing is the Bezold-Eidemann set of forks and whistles. The Weber experiment is one of the best known and most reliable tests made with the forks. It consists in placing the tuning fork C 2, 512 V., on the median line of the skull, and then closing the external meatus of one ear with the finger, under which conditions Weber found the sound lateralized toward that ear. The writer also describes the Politzer acoumeter, the Schwaback test, the Rinne test, the Galle test, and Bing test Nos. I. and II. He thinks that many of these tests are of great value in making a differential diagnosis and in estimating the probable course and termination of certain cases.

The Disinfection of Wounds with Pure Carbolic Acid.—Von Bruns states that carbolic acid in concentrated solution is relatively less toxic than when diluted, that its penetrability during its brief influence is but slight, and that the bactericidal action of pure carbolic acid surpasses that of sublimate in albuminous compounds. The cauterization with carbolic acid is not particularly painful, so that it may be performed without anæsthesia, and the subsequent pain after fresh incisions is also remarkably slight. The amount of secretion after the first dressing is very small, so that it need not be removed till from two to four days. The author, in his experience, has not noticed local injury, toxic symptoms, or carboluria. He recommends the application of pure carbolic acid in small quantities and for one minute, followed by immediate irrigation with absolute alcohol.

Three Cases of Myxœdema of Varied Type.—By W. Wyllys. Case I. was that of a woman aged sixty years, who presented a myxœdematous look, with slow speech, thickened features, etc., but became unmanageable and the victim of various hallucinations. She eventually died from acute mania. Case II. was that of a woman aged forty-five years, with apathy and a disinclination to get up. She complained that for the previous twelve months she had felt easily tired and languid and had repeatedly suffered from aching pains in the legs, and that the skin of her face and hands had assumed a yellow tint. She also said that her face had become puffy and that her teeth and her hair had fallen out, and also that the skin on her legs had become rough. She had suffered from menorrhagia, leucorrhœa, and chronic diarrhœa for some months. Her speech was of a measured type and her movements were slow. With these symptoms and signs Wyllys deemed a diagnosis of myxœdema to be logical, and accordingly prescribed five-grain tabloids of thyroidin, one to be taken

every night and morning, with the effect of which she was delighted, stating "that they made her feel much better." The urine was not examined. Case III. was that of a woman aged fifty-two years, who presented the evidences at first of Bright's disease, other symptoms which suggested some brain difficulty, and signs of atheroma of the aorta. She did well, however, on thyroid extract, and the progress of her malady finally rendered the diagnosis of myxœdema certain.

Mental Fatigue in School-Children.—By J. Bellei. The author's conclusions are based on observations made in the public schools of Bologna in Italy. He states that (1) he could not draw any conclusion as to the influence of the single subjects of teaching; (2) the first hour of lessons is a useful mental exercise, because the children are able during that time to overcome the state of inattention in which they were at the time of coming to school; (3) the morning lessons do not produce great mental fatigue; (4) the midday rest is of great use to the children because it does not destroy the good effects of the mental exercise in the morning and enables them to do work of better quality than that which they produce after a long rest, as one observes at the beginning of the morning lessons; and (5) though immediately after the midday rest the children are in the best conditions of mind, an hour or so of application in the afternoon is sufficient to produce such a mental fatigue as to lead at the end of the afternoon lesson to the worst work of the day. Therefore, if the morning application does not fatigue, it consumes the mental energy of the children in such a manner that they cannot undertake light work in the afternoon without falling into great mental fatigue.

Local vs. General Anæsthesia in Certain Cases of Abdominal Surgery.—By T. M. Morse. Certain histories of cases are given in detail illustrative of the following opinions of the author: There are some patients whose condition of extreme exhaustion is such that the additional shock of general anæsthesia will just take away their only chance of life. Most of these are refused operation. The cases referred to are those of acute peritonitis, internal hæmorrhage, and intestinal obstruction. In the last class there is an additional special danger in all cases of stercoraceous vomiting; when ether or chloroform is given it is very likely that while the patient is unconscious some of the fecal matter will be regurgitated from the stomach and sucked into the air passages. Now all of these are cases for operation with a local anæsthetic. They are all desperate cases in which the patients if left to themselves will nearly all die, but many can be saved by a dexterous operation if performed without general anæsthesia.

British Medical Journal, May 11, 1901.

Experiments upon the New Specific Test for Blood.—George H. F. Nuttall and E. M. Dinkelspiel have made investigations in this subject which confirm and extend the observations of others with regard to the formation of specific precipitins in the blood serum of animals treated with various serums. They conclude that these precipitins are specific, although they may produce a slight reaction with the serums of allied animals. The substance in the serum which brings about the formation of a precipitin, as also the precipitin itself, are remarkably resistant. The new test can be applied to a blood which has been mixed with that of another animal. This is the most delicate test known of detecting and differentiating bloods, and must become of great forensic use.

Responsibility and Crime.—Alexander Robertson reports several instances of the strange conduct of epileptics, which show that they are not infrequently really unconscious of doing apparently purposive acts of a criminal nature, though such acts may appear to be done consciously and with evil intent. They many times commit acts of violence of which they later show themselves to have been perfectly unconscious. It is not infrequent for them to be very sensitive about these "turns," which they dislike exceedingly to have mentioned.

Note on the Probable Relationship of Vaccinia to the Inoculated Form of Smallpox in Man.—S. Moncton Copeman describes numerous experiments which he has performed, their point of interest being found in the fact that whereas the human smallpox material employed could not be got to "take" directly on the calf, nevertheless results typical of ordinary vaccinia were obtained when the strain of lymph, after inoculation with it of a series of monkeys, was again transferred from the inoculation vesicles on this animal to the epidermis of the calf.

The Treatment of Dysentery.—Richard A. Mate gives the following treatment for dysentery, which in his experience is the only one he has found of any avail: R. Mag. sulph. ʒ i.; acid. sulph. dil. ♏ x.; quininæ sulph. gr. i.; tinct. opii ♏ x.; hydrarg. perchlor. gr. $\frac{1}{32}$; aq. menth. ad ʒ ss.; every three hours. He finds that patients derive great relief from an irrigation with a solution of boracic acid (ʒ i. to O i.). Tenesmus is relieved by the repeated application of turpentine stupes.

Diphtheria Antitoxin Administered by the Mouth.—W. Campbell McDonnell reports the case of a girl aged fourteen years, whose tonsils were both covered with a thick, soft, white pellicle, in which the diphtheria bacillus was found. Antitoxin serum was given by mouth and the child made a rapid recovery.

The Resection of the Wrist by the Double Longitudinal Incision, Dorso-Palmar or Transmetacarpal (Method of Studsgaard of Copenhagen).—Francis Villar concludes that the resection of the wrist by the method of double, longitudinal, transmetacarpal incision is easy to do. It offers a considerable opening and allows a good view of osteoarticular and tendinous lesions. It would be systematically indicated in all cases of osteoarthritis of the base of the metacarpals and of the carpal bones—especially those of the second row. It is very evident that in a limited lesion at the inferior extremity of the radius or ulna, a direct incision exposing the pathological focus would be the operation of choice. The same applies to a limited lesion of a metacarpal bone. In cases of lesions of the carpal bones longitudinal incision would be preferable to other methods for the following reasons: It is less laborious and it is more convenient for the extirpation of all the affected parts. There are certain other cases in which the double longitudinal incision is still more justifiable—cases in which the lesions, very extensive, almost demand amputation; cases in which, although the osseous lesions are not very extensive, still there are tuberculous foci in the synovial sheaths of the tendons of the wrist. In the first place, the large opening created by the incision more easily permits the removal of all of the affected parts and avoids the necessity of amputation. In the second case this method exposes the sheaths on all sides, and gives easy opportunity to remove all the diseased foci, whose ablation is a delicate procedure and sometimes incomplete when simple resection is used. The results which this method have given are, to judge from the published observations, excellent.—*Journal de Médecine de Bordeaux*, April 28, 1901.

Narcolepsy and Obesity.—The following case was reported by Paul Sainton. The patient was a man aged forty-three years, who was afflicted with obesity. For some time he felt no inconveuience, till at last he began to suffer from insomnia. After this an irresistible desire for sleep came over him. These attacks occurred during the day with varying frequency. They occurred especially at times when he wished to write. One time an attack came on as he was descending a staircase, and he fell, striking his forehead. This sleep was not always pleasant, and he woke several times with a feeling of indefinable anxiety. He began to eat less. He grew a little thin and the sleep crises were less frequent. He was not so tired; but he did

not continue to diet. Finally, he sought medical advice. The urine was quite normal in every respect. The patient was subjected to a special régime—fresh fruits, green vegetables; his drinks consisted of water and weak tea; before every meal he took ten drops of tincture of aloes. A little later he took clear bouillon. His weight decreased considerably. His intellectual and physical activity revived. He had no more narcoleptic crises nor nocturnal insomnia. The author believes that emphasis enough has not been placed on the rôle of this factor in the production of attacks of somnolence; for in obesity, as in most of the cardiac troubles in which it shows itself, narcolepsy ought to be regarded as having an autotoxic origin.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, April 28, 1901.

Epidemic Cerebro-Spinal Meningitis.—Dr. L. states that this disease generally begins bruskly and is rarely preceded by a prodromal stage. There are general malaise, headache, and pain in the dorsal region. Then follow chills, fever, and often vomiting. Opisthotonos is characteristic of this disease. Paralyses are often noted. These epidemics generally strike only limited groups of people and rarely extend to all the population of a town. It is especially active in cold weather. It is infectious. Isolation, however, is useless. It presents the characters of an infection, but the micro-organism is not yet definitely determined nor its port of entry into the organism. It is very often complicated by broncho-pulmonary affections, as well as affections of the sense organs and the articulations. The prognosis is dubious. As to the treatment, lumbar puncture is advocated by some. Hot baths probably give the best result. They calm the delirium. Cold baths are not beneficial. Ergot and potassium iodide have been proposed. The writer believes that the medication should be symptomatic.—*La Tribune Médicale*, April 24, 1901.

Transmission of Scarlatina to a Cat.—E. Rapin reports a case of this kind. The cat was only a few weeks old and belonged to a Russian family in which there were two little girls with this disease. The cat also fell ill. It cried for several days, its eyes were brilliant, its skin was rosy, and its tongue a vivid red. Its hair fell out in quantities. The baldness was observed over all the body surface. The skin looked scaly. The writer then details another similar instance of a cat taking scarlatina from a little child. He thinks that, although it may not be an absolute proof, still it is a sufficient proof that an illness bad been transmitted from a human being to an animal.—*Progrès Médical*, May 4, 1901.

Münchener med. Wochenschrift, April 30, 1901.

Blood, Body Cells, and Bacteria.—L. Heim describes some experiments undertaken to determine whether, in addition to the protective bodies supposed to exist in or be formed by the serum and leucocytes, the red cells also possess the power of resisting bacterial invasion. The earlier attempts were made with typhoid cultures and rabbit's blood, slaked by the addition of eel serum, but later experiments showed that this preliminary treatment was unnecessary. Briefly, the results obtained by adding a small amount of a bouillon culture of the organism to a hanging-drop preparation of defibrinated blood were, that after about four days had elapsed the red cells were completely dissolved and their contents set free, while the fact that the bacteria had been subjected to some destructive agency was made manifest by their loss of motility, semi-agglutination, and evident structural degeneration as shown by swelling and granule formation. It therefore seems that a new antiparasitic property of body cells and serum has been discovered, which appears when the invaders have overcome the alexins and begun to propagate. The contents of the red cells may at first provide a suitable culture medium for bacteria, or at least not inhibit their growth, but this is true only for a certain length of time, and after this the parasites are attacked and in part succumb to some destructive agent set free from the broken-down cells.

Poisoning from Canned Lobster.—Georgii reports the poisoning of twenty-four young men after partaking of a lobster salad made with canned material. From two to five hours later the symptoms set in and consisted of intense nausea, vomiting, pains in the back and limbs, severe headache and prostration, great pallor, and rapid, feeble pulse, the temperature remaining unaffected. In the absence of a stomach tube the necessary emptying and lavage of the stomach were effected by having the patients drink large quantities of warm milk and carbonated water. In the majority of cases this treatment was entirely adequate and recovery speedily followed the unloading of the stomach, but three patients in whom the symptoms had been slow to appear went into collapse with apathy and intense backache, so that removal to a hospital was necessary, where two or three days elapsed before they could be discharged. It is interesting to note that the urticarial symptoms common in fish intoxications were absent in these cases, and also that although no albumin was found, traces of sugar persisted in one patient's urine for several days.

A Suggestion for Preventing Auto-Extubation.—Schlechtendahl advises performing intubation in the usual way with the thread attached to the tube and emerging from the mouth. A Bellocq's cannula is then passed through the nares and the thread drawn out through the nostril, where it may be fastened in the usual way with adhesive plaster. The procedure practically entirely eliminates the risk of the child's drawing on the thread itself, while it is not exposed to the movements of the tongue, etc., in swallowing, which sometimes may assist the tube in slipping out of position. Extubation, when necessary, is not increased in difficulty, for the finger swept across the back of the pharynx easily hooks forward the thread when desired.

Extracranial Ocular Manifestations of Syphilis.—By O. Schwarz.

Blood Poisoning and Amputation.—By H. Dörfler.

Accident and Disability.—By E. Kiefer.

Deutsche med. Wochenschrift, April 25 and May 2, 1901.

The Technique and Applicability of Subcutaneous Quinine Injections.—Bluemchen says that although in many instances the subcutaneous use of quinine would be desirable, still the more usual forms of hypodermic solution are open to serious objections. The sulphate is out of the question owing to its insolubility, while the muriate requires the addition of hydrochloric acid or alcohol to make it sufficiently soluble for use, and such preparations, as well as glycerin solutions, produce almost prohibitory local lesions. The injection itself is accompanied by severe pain and is followed by dense infiltrations, which not only persist indefinitely but are permanently painful, while necrosis is not infrequently observed. All of these disadvantages may be obviated by making use of the fact that the muriate is very soluble in hot water, and that considerable amounts of the salt are held in solution even when the fluid is cooled down to body temperature. Using this principle, the author has devised the following technique: The hypodermic syringe and needle are boiled in a small vessel and the syringe is filled with the boiling water. The rest of the water in the vessel is thrown out and 7.5 grains of the muriate of quinine put in and the water in the syringe squirted over it. A clear solution results, which by the time that it has been drawn back into the instrument will have cooled down to about 98° F. The best place for injection is between the shoulder blades, and on the removal of the needle a hot compress is applied to produce local congestion and facilitate absorption. The advantages of the method are its safety, painlessness, prompt and certain action, cheapness, and simplicity.

The Bacillus Described by Danysz as Pathogenic for Rats.—J. Kister and P. Köttgen cite the results obtained by Danysz in studying this organism and add some corroborative observations of their own. The bacterium is a short, narrow, actively motile bacillus which differs from the members of the coli group in neither producing indol nor causing the curdling of milk. In pure culture it causes the death of rats in from five to seven days, and of mice in from four to seven, and experiments conducted on a large scale have shown that it is possible widely to disseminate the disease among the animals in question, since the dead bodies are consumed by the survivors and the infection rapidly spreads in this way. The importance of the observation lies in the fact that the present theories of the propagation of the plague give the rat an important rôle as carriers, and the wholesale extermination of the vermin may become a prophylactic problem. It was found that the virulence of the organism is rapidly decreased by passage through the animal's body, the day of death for mice being postponed to the tenth day after ten successive injections, while for rats it loses its virulence entirely. Pure cultures also lose considerably in power with keeping, the most favorable nutrient medium being agar. No danger to the domestic animals, poultry, etc., is to be apprehended in case the bacillus should be used as an exterminating agent, for experiment has shown the complete immunity of all non-rodents to it.

The Alterations in the Malarial Parasites during Treatment with Methylene Blue.—A. Iwanoff contrasts the action of methylene blue and quinine on the malarial organism as follows: In the immature stages of development the relation of chromatin to protoplasm in the parasite is different from what it becomes later on, and the effects of the two drugs vary accordingly. Methylene blue is particularly active in attacking protoplasm, while the nucleus and chromatin are especially susceptible to quinine, hence the young forms which are poor in protoplasm resist methylene

blue but are strongly acted upon by quinine; the adult parasites, which are mainly protoplasm, rapidly succumb to methylene blue, and the crescents, consisting almost wholly of protoplasm, are absolutely refractory to quinine but completely destroyed by the other drug. If a patient whose blood contains the tertian parasite receives five grains of methylene blue three times a day, no change in the structure of the organisms is produced till the end of the second or beginning of the third day of medication. At this time in adult forms a considerable diminution in the power of amœboid motion is observed, as well as a subdivision of the protoplasm into droplets. Sporulation forms also manifest considerable changes, the number of spores being diminished and their outlines made irregular and the protoplasm scanty, while the chromatin is conspicuously unaffected.

The Organism of Vaccinia Described by Funck.—W. Podwyssotski and A. Mankowski publish the result of a series of observations undertaken to investigate the nature of the so-called protozoa of vaccinia recently described by M. Funck. The conclusion reached is that the bodies in question are sebaceous glands and epithelium that have undergone fatty degeneration, since staining with soudan, osmic acid, alcannin, and chinolin blue gave positive results, the addition of acetic acid caused a nucleus to appear, and ether dissolved the so-called spores completely.

The Aims of Functional Diagnosis and Observations on the Blood as an Organ and the Regulating Function of the Kidneys.—By O. Rosenbach.

Further Observations on my Method for the Detection of Human Blood.—By Uhlenhuth.

A Case of Otogenic Meningitis Terminating Favorably.—By Bertelsmann.

Incomplete Sugar Oxidation in the Organism.—By P. Mayer.

The Serum Diagnosis of Tuberculosis.—By E. Romberg.

Berliner klinische Wochenschrift, April 22 and 29, 1901.

Observations on the Diagnostic Value of the Freezing-Point of the Blood.—A. Koranyi gives as the lowest limit to which the blood freezing-point may drop, without indicating renal insufficiency, 0.58° C., while a figure of 0.59 C. is already significant of inadequacy of both kidneys. The causes of such insufficiency may be various; for example, there is a reflex insufficiency due simply to pain in the one organ while the other is perfectly healthy, and certain mechanical conditions like the presence of large abdominal tumors, whether renal or not in origin, may have a similar effect. Therefore, the blood freezing-point is to be taken as an index of disease of both kidneys only when such extraneous factors can be excluded. The conflicting figures which have been published by other observers the author attributes to the lack of certain precautions which it is essential to observe. Chief among these is the employment of sufficiently large quantities of blood; at least 10 to 15 c.c. are required, but as the freezing-point of blood and serum are the same, the troublesome separation of the serum is unnecessary and the attendant waste of material is saved. Another point not to be neglected lies in the elimination of the carbonic acid, which is always present in excess, no matter in what manner the blood is obtained, and as it is variable in amount introduces an inconstant factor into the calculations that must be obviated by a preliminary saturation with oxygen either directly or simply by agitation with air. By the use of Beckmann's apparatus the determination may be quickly made and is accurate to 0.01° C., which is all that is required.

Laryngeal Complications of Influenza.—W. Lublinski says that, although the laryngitis of this affection as a rule does not differ from that ordinarily observed, still at times it presents some peculiarities. Among these are the intense redness and swelling of the mucosa, especially of the vocal cords, frequently seen in grippe laryngitis, as well as the distinct type of hemorrhagic laryngitis, which is to be classed with the hemorrhagic inflammations of the serous and other mucous membranes, such as hemorrhagic pachymeningitis, gastro-enteritis, etc. As a rule the subglottic type sometimes occurring is not accompanied by any serious symptoms, but occasionally it is followed by œdema of the mucous membrane, which requires prompt treatment to avoid severe dyspnœa and dysphagia. In other cases white patches form which ulcerate and go on to necrosis of the soft parts with denudation of the cartilages and abscess formation. These may rarely be due to thrombosis of a vessel, but more often are caused by the intense local congestion. Of other laryngeal complications of influenza recurrent paralysis is not unusual, and posticus palsy has several times been described, as well as temporary functional involvements of the vagus, manifesting themselves as disturbances of the heart, respiration, and soft palate. The prognosis in these cases is favorable, recovery taking place in from four to six weeks.

A Case of Gastric Carcinoma Running a Singular Course.—B. Lewy describes a case of this affection, remarkable for the unusual clinical picture presented. The patient, a middle-aged man, had been under observation for about ten years suffering from obscure stomach symptoms which pointed somewhat to malignant disease, though a positive diagnosis was impossible. About two years before death he was taken with a painful swelling affecting first the one and then the other pectoral region. This was first diagnosed as a polymyositis and then as a lympho-sarcoma; it improved considerably under local injections of Fowler's solution, but this treatment had to be discontinued owing to the patient's susceptibility to the poisonous effects of the drug. At the autopsy there was found a carcinomatous growth of the stomach originating in an old ulcer, with multiple metastases in the mesentery, large intestine, and muscles; the usual sites of secondary deposits, such as liver, spleen, and pancreas, being spared.

Splashing and Atony.—H. Elsner is inclined to deprecate the value of this sign as an indication of gastric atony and states that in general it may be considered of little importance. In cases in which the stomach occupies a normal position it points toward atony only when present in the fasting stomach, or if it still persists seven hours after a test meal. Under the latter circumstances it may be taken as a very imperfect substitute for the stomach tube. In gastroptosis absolutely no value attaches to the sign.

The Conservative Treatment by Vaginal Incision of Pus-Containing Tumors of the Adnexa and their Sequelæ.—By A. Dührssen.

The Energy Equilibrium of the Infant.—By O. Heubner.

Nervous Tachypnœa.—By Reckzeh.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

PLAGUE PRECAUTIONS—CLINICAL EXHIBITS—LYMPHADENOMA—PATENT DUCTUS ARTERIOSUS—MYXŒDEMA—INTESTINAL SURGERY FOR DOUBTFUL CASES—ARTERIAL HEMORRHAGE FROM THE EAR—LEUKÆMIA—APPOINTMENTS—FELLOWSHIPS—DEATHS OF DRS. CAVAFY, SAMUELS, AND LORIMER.

LONDON, May 3, 1901.

PLAGUE has begun to enter into our conversation, but no one seems to entertain any apprehension, although every one approves of the precautions that have been taken against the invasion of the disease. The county council has adopted the measures recommended by the public health committee, and the asylums board is co-operating with it. The arrangements made place at the service of every practitioner the expert advice of Mr. Cantlie, who has been retained by the council and who will visit any suspicious case. His long experience in China is therefore available for diagnosis. On his certificate any case will be isolated by the asylums board, while the council will provide isolation houses for contacts. Furthermore, in all suspicious cases a bacteriological examination will be made by Dr. Klein. The local dormitory authorities will undertake the destruction of infected articles and the disinfection of houses.

These measures seem to inspire confidence that we shall escape the scourge, although there is a degree of divided responsibility which seems unfortunately necessary.

As to the ports, in reply to a question in the House, the president of the local government board said special memoranda had been issued to all the local authorities, and further instructions would be forwarded as might be thought desirable. An inspector of the board would be sent to confer with the local officers of health in any threatened port, and every effort made to prevent the introduction of the disease.

On Tuesday it was stated in the House that a few fresh cases had occurred in Cape Colony. This morning the newspapers published an ominous telegram that a suspicious case had appeared at Mafeking.

One of the memoranda of the government board relates to ship-borne rats, and directions are given for the prevention of plague entering through the rats. The destruction of these rodents should be carried out both on board ships and on land. There is ample evidence that they convey disease, and at the best they are a nuisance. I am sorry the board has not advised the plan reported from

your side the Atlantic of destroying them on ships by sulphur fumigations, which should be fatal to other vermin as well as rats.

The clinical evenings at our societies are often specially instructiye and interesting on account of the various views taken of the cases exhibited. Perhaps it would be well if some of the cases in the law courts could be subjected to a similar ordeal. That might prove a better method than the consultation between medical witnesses so often proposed. Some of the patients shown at the Clinical Society last Friday illustrate the different points of view which may be taken of cases by competent observers. A lad of sixteen years was shown suffering from what was called chronic general lymphadenoma. He had taken a prolonged course of arsenic, during which lymphoid growths developed on the skin, but which decreased on the suspension of the treatment. It was said that the lymphatic glands all over the body had been affected, and that there was decrease of the red blood corpuscles with some increase of the white. A suggestion was thereupon made by a member that it might be a case of mixed tuberculosis and hereditary syphilis. Another member thought the swelling had a tuberculous look, while the patient had not the facies of lymphadenoma. A case was mentioned in which similar swellings had been seen in the skin associated with lymphadenitis. In reply to a question it was stated that microscopically the character of the swelling was that of lymphadenoma.

A woman of twenty-one years was shown as suffering from patent ductus arteriosus. There were some slight cyanosis; a faint diastolic thrill in the second left space; acute second sound, feeble first sound, generally doubled; and at times a short diastolic murmur. She had had cardiac symptoms from childhood, dyspnœa for the last three years, and there was no history of rheumatism, chorea, or scarlet fever. In this case one suggestion made was that it was one of aortic regurgitation. This was disputed and another suggestion made of tricuspid stenosis, and yet a third of congenital mitral stenosis. The president hoped the case would be kept under observation.

A girl was shown who had recovered from a condition of myxœdema under the use of thyroid extract. The history suggested a congenital origin. One member, therefore, thought it should be described as cretinism, especially as the presence of mucin in the tissues had not been confirmed.

The meeting of the Medical Society was occupied with intestinal surgery. Mr. Barker related a case of a woman of thirty-nine years who left the hospital on the sixteenth day after operation for hernia, but returned later with obstruction and general peritonitis. The abdomen was reopened and the bowel found kinked in the hernial sac. It was greatly shrunk, and enterectomy seemed the only resource. This was performed, thirty-seven inches being removed and end-to-end anastomosis done. Recovery followed. Mr. Barker recalled other cases in which he regretted not having resected instead of leaving the chance of the bowel recovering its vitality without adhesions.

Mr. Morgan (president) would hesitate to resect the bowel if it had any sign of vitality, for many cases of great damage ended in recovery, and it was very seldom that the abdomen had to be opened for obstruction after the bowel had been returned.

Mr. Malcolm thought in this case the bowel might have recovered. In all such operations there is liability to adhesions, and therefore he questioned the propriety of resection. He lately put back a bowel matted with adhesions and the patient did well.

Mr. Moullin then read a case of obstinate atony of the colon in which he had short-circuited the intestine by anastomosing the lower end of the ileum with the sigmoid flexure. The patient had suffered for seven years or more. For five years nothing had passed without an enema attended by severe pain. The abdomen had been opened three times previously. It was opened for a fourth time and the anastomosis established. The next day a liquid motion passed naturally, the first time for five years. The patient gained a stone in weight, and left the hospital well. Recently Mr. Moullin heard that constipation is returning, suggesting contraction of the anastomotic orifice, which is sure to occur unless the orifice is of enormous size.

Mr. Morgan said such operations must rarely be necessary; it would be interesting to know what happened to the intervening portion of colon.

Mr. A. Doran thought probably in such cases the small intestine was also atonic and that the origin was nervous and central. He asked if it would be justifiable to resect for tympanites.

Mr. Malcolm referred to a similar case in which he had operated several times. He had removed the appendix, opened the cæcum, and also removed part of the colon. He now proposed to anastomose.

Mr. Barker said he had anastomosed a case on account of the distress caused by a fecal fistula following appendicitis. He thought transplantation preferable to inguinal colotomy for cases of chronic colitis.

Mr. Moullin, in reply, admitted that many cases were of neurotic origin, but still operation was justifiable in some of them.

At the Medico-Chirurgical Society Mr. W. G. Spencer related a case of arterial hemorrhage from the ear necessitating ligature of the carotid. A boy of four years soon after scarlet fever had recurrent hemorrhages from nose, ear, and mouth. Plugging arrested it for a time only. On the fourth recurrence he was pulseless, unconscious, and losing much blood. Two pints of saline solution were injected into the cellular tissue of the axillæ and flanks, and caused swellings the size of his head. The common carotid was tied low down in the neck. After the operation the saline fluid was found to have been absorbed, the pulse improved, and hemorrhage did not recur. The boy recovered. Three weeks later a perforation was seen in the membrana tympani. The source of bleeding was supposed to be the small twig from the internal carotid which passes through the carotid canal. Mr. Spencer thinks cases arising after acute inflammation in children favorable for operation, but those secondary to pulmonary tuberculosis would sooner or later be fatal from the lung disease.

Dr. A. G. Phear then gave particulars of a case which he called acute leukæmia, the principal symptoms being: (1) marked increasing anæmia, (2) moderate fever, (3) stomatitis, affecting chiefly the gums, which were spongy and later ulcerated, (4) enlarged glands, at first of the cervical and submaxillary, but afterward generally, (5) moderate splenic enlargement, (6) leukæmia. The patient died in six weeks. At the post-mortem the thymus was found persistent; the lymphatic glands, tonsils, spleen, and intestinal follicles were enlarged and contained cells resembling blood lymphocytes. The bone marrow was also full of them. There seems to have been an overgrowth of lymphoid tissue, the cells being for the most part mononucleated and so far unusual, but they had been found in large numbers in the blood during the patient's life.

Dr. Bradford remarked that little was known about acute leukæmia, and even the name was perhaps not suitable. The cases closely resembled stomatitis and were perhaps due to infection from the mouth. The enlargement of the glands is usually moderate. Purpura, with stomatitis and pallor, should lead us to suspect the disease. In future it would be interesting to examine the marrow and the blood for protozoa.

Dr. Reissmann said these cases were much more rare than myelogenic leukæmia, in which the cells, found in increased numbers, were granular leucocytes. In lymphatic cases the increase was of the non-granular. Their number increased with any alteration in the circulation of the lymph through lymph tissue, *e.g.*, during digestion, and after pilocarpine injections. Probably both forms of leukæmia were parasitic. Mr. Spencer agreed with this and thought the point of entry probably was the tonsils.

Sir T. Barlow referred to a boy admitted to hospital with inflamed tonsils, not diphtherial. Enlargement of glands about the jaw followed and spread to other glands. He died in about four months, and central necrosis was found in some of the glands. The origin of such cases in the mouth or throat differentiated them from those in which stomatitis occurred.

Dr. William Collingridge has been elected medical officer of health for the city of London. He has for twenty years held the appointment to sanitary authority of the port of London.

Two doctors, who are also both barristers, are candidates for the office of coroner for the city. Either would be a good choice.

The committee for making a full inquiry into the affairs of the National Hospital has been appointed.

Some new fellows have been co-opted by the College of Physicians. We shall have the old grievance once more trotted out. For my part, I have no objection to any of the new names, except that there are many times their number quite as worthy and for many years longer members.

Dr. John Cavafy died suddenly on the 28th ult. He was for many years physician to St. George's Hospital, during which he published a number of contributions to the societies and journals. Of these I may mention cases of rheumatism, diabetes, and myxœdema. He took special interest in dermatology, and acted as honorable secretary to the skin section at the International Congress, 1881. He had served as examiner in medicine at the London University, of which he was himself a graduate, having taken the M.D. in 1869. On account of declining health he retired from practice some years ago.

Among other recent deaths are those of Dr. Samuels, many years physician to the Liverpool Hospital for Chest Diseases, on the 21st ult.; of Dr. Lorimer, of Farnham, in consequence of a carriage accident on the 27th ult.; of Dr. Galletly, of Elgin, on the 26th ult., also the consequence of a similar accident.

Reviews and Notices.

Transactions of the American Ophthalmological Society. Vol. ix. Hartford: Published by the Society. 1900.

This report contains an unusual number of well-illustrated articles. The papers are all of a high order. Accompanying the obituary of Dr. Edward L. Holmes is an excellent portrait of this distinguished surgeon.

The Nursing Profession: How and Where to Train. By Sir Henry Burdett, K.C.B. London: The Scientific Press, Limited. 1901.

This is the third year's issue of a guide for those seeking to become nurses in the United Kingdom, with a summary of laws affecting nurses, requirements of schools, and such general information. Naturally this work, valuable abroad, can have little interest for the average American nurse.

First Aid Handbook. By M. J. Shields, M.D., formerly Attending Surgeon to Emergency Hospital, Carbondale, Pa. Jermyn, Pa: Edited and Published by Thomas Boundy.

This is a collection of instructions for rendering effective and intelligent first aid in accidents and sudden illness, modelled after similar small works and based upon experience.

The Soul of Man: An Investigation of the Facts of Physiological and Experimental Psychology. By Dr. Paul Carus. With 182 illustrations and diagrams. Second edition. Chicago: The Open Court Publishing Co. London agents: Kegar Paul; French, Trübner & Co., Ltd. 1900.

This is a new edition belonging to the Religion of Science Library, and treats of that which should be the most interesting of all things to man—his soul. The problem of the soul supplies the basis of ethics, and the author, who has written many works on similar problems, strives to treat here of man's soul in a purely scientific manner with perhaps new interpretations.

Essentials of Surgery, Arranged in the Form of Questions and Answers, Prepared Especially for Students of Medicine. By Edward Martin, A.M., M.D. Illustrated. Seventh edition, revised and enlarged, with an appendix. Philadelphia: W. B. Saunders. 1900.

This is one of the blue-backed question-compend series put out by the publishers on various subjects. The volume as it stands revised represents the modern surgical practice. Besides other subjects which have been brought up to date we note that appendicitis has received new treatment at the hands of the author.

A Medico-Legal Manual. By William W. Keysor, Lecturer on Medical Jurisprudence in the Omaha Medical College, etc. Omaha: Burkley Printing Co. 1901.

The author finds that most works on jurisprudence contain little of actual practical value to the physician, being written mostly for the lawyer. The aim here is to furnish useful information of particular importance to the doctor, dentist, and pharmacist, leaving out what is of necessity learned in the schools as a basis for more practical matters.

Enteroclysis, Hypodermoclysis, and Infusion: A Manual for Physicians and Students, with a chapter on the Carbonated Bath, and some New Applications; also Therapeutic Addenda. By Robert Coleman Kemp, M.D., New York. Introduction by William H. Thomson, M.D., LL.D., physician to Roosevelt Hospital; President of the New York Academy of Medicine, etc. Infusion, Shock, and Anæsthesia, by Robert H. M. Dawbarn, M.D., Surgeon to the City Hospital; Professor of Surgery at the New York Polyclinic Medical School, etc. Drawings by Thomas Nast, Jr. Photographs by Dr. A. W. Gardner. New York: James T. Dougherty.

This work of three hundred and fifty pages is freely illustrated, showing the various devices mentioned by the author, position of patient in administration of enemata, infusions, etc. The material is comparatively new and largely original. Many useful hints are to be found in the therapeutic addenda. Students, and especially practitioners, will find it a very practical and very helpful book.

A Treatise on Appendicitis. By George Ryerson Fowler, M.D., Professor of Surgery in the New York Polyclinic, etc. Second edition, revised and enlarged. Philadelphia and London: J. B. Lippincott Co. 1900.

The changes and improvements in this edition of this book well represent the advance in our knowledge in the treatment of appendicitis during the last six or seven years. These changes have been considerable, and they require considerable recasting of our statements in regard to this common disease. The treatment by operation of the relapsing cases is on a much better footing than formerly, and we think that we now know how to treat in a more satisfactory way those cases with extensive peritonitis. This volume forms an excellent handbook of the subject and is well up to date. The precautions mentioned as necessary in the preparation of a room in a dwelling for an operation are much too elaborate for ordinary use, and in fact many of them need not be observed. The illustrations, as in the former edition, are very satisfactory.

A Compend of Human Physiology, Especially Adapted for the Use of Medical Students. By Albert P. Brubaker, A.M., M.D., Adjunct Professor of Physiology, Jefferson Medical College. Tenth edition, revised and enlarged. 12mo, pp. 270. Philadelphia: P. Blakiston's Son & Co. 1900.

This very popular compend has reached its tenth edition, which is revised and enlarged. It is thoroughly up to date, and invaluable to the student preparing for his examinations.

Nursing Ethics: for Hospital and Private Use. By Isabel Hampton Robb, Graduate New York Training-School, Bellevue Hospital. 12mo, pp. 273. Cleveland: J. B. Savage.

This is an admirable book of its kind. The various subjects are treated with great skill and in such an entertaining way as cannot fail to impress the reader with the eminent fitness of the author for her task. The knowledge of her profession and the appreciation of the responsibilities of the nurse are manifest on every page. The ethics taught are of the best and contain many points which would be useful and suggestive to many physicians. As a book for nurses it is destined to have a wide circulation when its many merits are duly appreciated.

A Manual of Practical Hygiene for Students, Physicians, and Medical Officers. By Charles Harrington, M.D., Assistant Professor, Harvard University. Illustrated with 12 plates and 105 engravings. Philadelphia and New York: Lea Brothers & Co. 1901.

This work is a very important and satisfactory contribution to the literature of its subject. So much ground must necessarily be covered in a volume of this kind that to reduce it to any reasonable size is an achievement in itself About one-third of the book is given to the consideration of foods, their kinds, constituents, value, methods of preservation, and other facts of importance regarding them. The information is almost encyclopædic in its accuracy and completeness. Air, soil, and water are considered in separate chapters, which cover the subjects in a satisfactory and interesting way, and impart much information useful to the professional man and also to the layman. The important subjects of quarantine and naval and military hygiene have chapters devoted to them, all containing much of interest and value, and there are several other chapters on various divisions of sanitary science. The whole book is characterized by accuracy and careful attention to detail; its illustrations are very useful, and it is a credit to American medical science. The pages devoted to tropical hygiene will be read with peculiar interest just now.

Operative and Practical Surgery, for the Use of Students and Practitioners. By Thomas Carwardine, M.S. (Lond.), F.R.C.S., Assistant Surgeon Bristol Royal Infirmary. With 550 illustrations, most of which are original drawings by the author. Bristol: John Wright & Co. London: Simpkin, Marshall, Hamilton, Kent & Co., Limited.

The author of this volume has succeeded in carrying out the intention stated in his preface, of offering a manual of practical surgery without the enormous amount of detail found in most works upon this subject. He has written what is essentially a handbook to be used in conjunction with larger works. The book is intended to cover the whole field of surgery, and is naturally open to some of the objections which such an intention necessarily involves. The chapter upon bandaging is very satisfactory and practical, and the discussion of fractures is good as far as it goes. The operations of surgery are given as full attention as is possible under the circumstances, but much that would generally be considered valuable is left out. From the American point of view the remarks upon appendicitis are weak and somewhat antiquated. However, the volume as a whole makes an agreeable addition to surgical literature. We think it unsatisfactory to attempt to include such subjects as otology and ophthalmology in works on general surgery. Much better results are attained by leaving those subjects to the men with special training.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 2, 1901.

ROBERT F. WEIR, M.D., PRESIDENT.

Remarks on the Statues and Temples of Esculapius, with Presentation of Photographs.—DR. C. L. DANA made this presentation, accompanied by some explanatory remarks.

The Clinical Aspects of Acute Intestinal Obstruction.—DR. HOWARD LILIENTHAL read this paper. He said that death rarely if ever occurred from the mere retention of fæces in the bowel. The causes contributing most to the mortality of intestinal obstruction were three, viz., (1) shock, (2) sepsis, and (3) the embarrassment of the functions of the lungs and heart by the distention. Either of the first two causes might be fatal without the existence of the third. Deaver had called attention to the fact that appendicitis was a cause, and he was himself of the opinion that ileus was often due to appendicitis. Tight strangulation in the small intestine, occurring suddenly, was accompanied by intense colicky pain, nausea and vomiting, and collapse came on early. An enema, given for diagnostic purposes, should show by the quantity of water retained that the trouble was not in the colon. The nearer the strangulation was to the stomach, the more urgent was the need for speedy relief. In elderly individuals, constricting neoplasms of the colon were not rare, and might give rise to symptoms simulating intestinal obstruction. In volvulus the loop of bowel distended very rapidly. The discharge of foul gas was an indication that the complete obstruction had been overcome, and this sign was of far more importance than the mere discharge of fæces. Sudden abdominal cramp-like pain without fever should be treated by an enema, and, in the adult, by a small dose of morphine. If permanent relief did not follow, it was safer to operate than to temporize. The further exhibition of opiates or the employment of cathartics would probably introduce an additional element of danger. Ischuria and great dryness of the mouth were of diagnostic value. Some interesting recoveries following the administration of atropine had been reported, but it should be remembered that atropine increased the uncomfortable dryness of the mouth, and sometimes gave rise to a delirium which was with difficulty distinguishable from that of sepsis. His impression was that this treatment, if used at all, should be in cases of acute exacerbation of a chronic ileus, and simply as a means of tiding the patient over a critical period. As an early procedure, it was justifiable to employ enemata in the attempt to secure a reduction of the obstruction. Little could be expected from this treatment, however, and nothing at all if the intussusception had resulted from a reversed peristalsis. The speaker said that since 1893 he had done thirty-four operations for acute ileus, with forty-one per cent. of recoveries. The stomach should be washed out before operation, and in the most desperate cases no general anæsthetic should be used. The incision should be made in the right iliac region, and if this did not reveal the obstruction a median incision should be made. The possibility of multiple obstruction should ever be borne in mind. When there was great distention, a sufficient number of small incisions should be made opposite to the mesentery to allow of reducing the distention before search was made for the source of the obstruction. He had practised this method for some time, yet, on presenting it to the New York Surgical Society in October, 1898, it had been adversely criticised. He had, nevertheless, continued to practise it, and had seen nothing but good from it.

DR. B. FARQUHAR CURTIS said that he did not find that cases of intestinal obstruction came to the surgeon any earlier now than they did many years ago. About the only recent addition to the symptomatology was the presence of leucocytosis as an indication of peritonitis, and this would be found a diagnostic aid of some value. In making the diagnosis, one must distinguish between intestinal obstruction and peritonitis, pancreatitis, or thrombosis of the mesenteric vein. When called to a case of subacute or acute intestinal obstruction, appearing in an elderly person, his first thought was of malignant disease. The presence of a rounded gaseous tumor was of very great value in locating the trouble. One should not forget that valuable information might be furnished by a digital examination of the rectum. A preparatory washing out of the stomach was very useful. He believed a very large number of these patients could be saved by the making of an artificial anus. As far back as 1888, he had collected statistics to show that fully three-fourths of the cases were relieved by the establishment of an artificial anus, that half recovered, and that fully one-third of the latter were entirely cured of the intestinal obstruction. Such an operation could be done quickly and under local anæsthesia, and in this way it became in many desperate cases a veritable life-saving measure.

Intussusception.—DR. C. L. GIBSON exhibited a table founded on 187 acute cases. On the first day the mortality had been 37 per cent.; on the second day, 39 per cent.; on the third day, 61 per cent.; on the sixth day, 75 per cent. On the first day 94 per cent. were reducible; on the second day, 83 per cent.; on the third day, 61 per cent., and on the sixth day, 50 per cent. One should, therefore, operate early enough in intussusception to find it reducible and before secondary changes had taken place. While no doubt the establishment of an artificial anus was often a life-saving measure, it should be remembered that one must not only relieve the obstruction, but properly treat the sequelæ of this obstruction. Such an operation was often done and the gangrenous portion of the bowel left untreated. This was particularly likely to happen because it was common for the outside of the bowel to show a good condition of the circulation, while the mucosa, if examined, would be found gangrenous. This fact also explained why many resections went wrong.

The Medical Diagnosis.—DR. MORRIS MANGES said that Mikulicz had recently quoted statistics from 70 cases of acute intestinal obstruction subjected to operation. Of this number, 34 had resulted in recovery. Of the 34 fatal cases, 14 had already had peritonitis and 7 gangrene of the intestine—in other words, 21 cases might have been placed among the recoveries. The duty of the medical man was to make the diagnosis and then promptly call in a surgeon. The great point to remember in making the differential diagnosis was the presence of shock in intestinal obstruction, associated with more or less pain and vomiting. No attempt should be made in these cases by medical men to make an exact diagnosis, for even those most skilful in abdominal palpation were apt to be baffled because of the great abdominal distention, even under an anæsthetic. A digital examination of the rectum was of far greater value in the making of the diagnosis. The presence of albuminuria indicated strangulation or peritonitis, if it was known that no albumin had been in the urine previously. Hæmaturia was sometimes associated with acute intestinal obstruction. The mere discharge of gas after an enema should not be regarded as indicative of partial relief of the obstruction, unless the gas was foul in odor. He was inclined

to think that the atropine treatment of intestinal obstruction would prove a delusion and a snare.

Diagnosis of Intussusception.—Dr. Henry Koplik discussed the difficulties of diagnosis in acute intussusception. He said that when these cases occurred in children, although the obstruction might be acute, the onset might be quite insidious. One should not call in the surgeon simply to divide the responsibility, but should try to make the diagnosis before doing so. Both vomiting and bloody movements might appear at first, and then disappear for twelve hours. In his opinion, it was most important to give an anæsthetic to children in order to make a satisfactory physical examination. There was very little prostration at the beginning, and sometimes not even on the second day. To wait until the occurrence of fecal vomiting before making the diagnosis was most culpable.

Dr. R. F. Weir commented upon the great and dangerous distention caused in many of these cases by the administration of enemata in the hope of reducing the tumor. This suggested the advisibility of leaving a long tube in the rectum so as to empty the bowel.

Dr. E. H. M. Sell reported a case that he had seen some years ago. The patient, a woman of twenty-three years, had been first seen by him when vomiting fecal matter. Examination of the rectum was negative. He had then given her one bottle of warm olive oil daily for ten days, and then she had been relieved by the passage of what, from the description, might have been a slough of the bowel. An external fistula had formed, but she had eventually recovered. He had never been able to satisfy himself as to what was the exact diagnosis in the case.

Stated Meeting, May 16, 1901.

Robert F. Weir, M.D., President.

Memorial Address on the Late Dr. S. S. Purple.—Dr. Stephen Smith delivered this address. He said that Dr. Purple had had a very meagre education up to the age of sixteen, and that then he had been compelled to devote all his time to his father's business, that of a tanner and shoemaker. It was about this time that he had begun to manifest interest in medicine. It was his custom to rise at four o'clock in the morning and study his medical books until seven, and then go to his work. During the day he read as he could from a book fastened on a rack before his bench. He subsequently entered the Geneva Medical College, a noted institution at that time. In the autumn of 1843 he came to New York and took a course of lectures at the New York University. He graduated in March, 1844, and having carefully considered the advantages and disadvantages of city practice, he decided to make a beginning in New York City. He worked his way thither on a canal boat, and arrived here with $17.50 as the capital on which to begin his medical career. The first three years were trying ones, but by the fifth year he had succeeded in gaining a good foothold. He aided in organizing the New York Academy of Medicine in 1847, and from this time on for about ten years he was editor of the New York *Journal of Medicine*. His chaste and logical style of writing was remarkable considering the limited opportunities he had had to secure an education. All of his medical papers were published during the first decade of his medical career, as the after years were largely devoted to satisfying his fondness for bibliography. He was elected president of the Academy of Medicine in 1875. In his inaugural address there he urged the founding of a large reference library, and the securing of a home for the medical profession of this city. To the library of the Academy of Medicine he gave that priceless treasure, the complete early serial medical literature of this country. This, it was generally admitted, had laid the foundation for the now splendid reference library possessed by the Academy. In closing, Dr. Smith made an earnest plea for greater effort to keep green the memory of medical pioneers. He said that as a step in this direction the committee which he represented had secured two memorials of Dr. Purple, viz.: one a bronze tablet at the entrance to the library of the academy, announcing that he was the founder of that library; the other memorial, an excellent portrait of Dr. Purple secured for the academy through the generosity of Mrs. Edwin Harper.

Sitophobia of Enteric Origin.—Dr. Max Einhorn read a paper with this title. He used the term sitophobia only in connection with those cases in which there was a distinct fear of taking food. Two cases were cited in which the sitophobia had been dependent upon a disordered state of the bowel, associated with obstinate constipation. The sitophobia in these cases had had its origin in the belief that the taking of food might aggravate the bowel affection. The patient must be made to eat sufficient food. Sometimes persuasion would accomplish this; at other times it was necessary to enlarge the dietary very gradually.

Syphilis of the Liver.—Dr. Einhorn also read a short paper on this subject. He briefly reviewed the literature, and then reported ten cases. He said that there were three varieties of syphilis of the liver, viz.: (1) Gummata; (2) syphilitic cirrhosis, and (3) syphilitic disease of the foregoing types associated with icterus and running an acute course. In syphilis of the liver there was usually more or less severe pain in the epigastrium, sometimes simulating gall-stone colic. If of long standing, there would be some emaciation, but nothing like that seen in cases of malignant disease of the liver. In the late stages a light-brown discoloration of the skin might be observed. Physical examination would show the liver enlarged and often nodulated. In the advanced stages when amyloid change had taken place the surface of the organ would be smoother. The diagnosis was most easily made in cases in which there were gummata of the liver together with other signs of recent syphilis. When there was simple enlargement of the liver without gummata or a history of syphilitic infection, it was most difficult to make the diagnosis. Gummata of the liver were easily confounded with malignant neoplasms. If the disease had lasted a year and a half or longer without marked deterioration of the general health, it was probably syphilitic. Diffuse syphilitic enlargement of the liver closely resembled hypertrophic cirrhosis of this organ. One author had cited thirty-four cases of syphilis of the liver, with twenty-nine deaths, but it should be remembered that most of the reported cases had been far advanced. According to Dr. Einhorn's experience, the prognosis was favorable if the disease was recognized early and promptly and efficiently treated. Iodide of potassium or iodide of sodium should be administered in rapidly increasing doses. He had seen the best results from the combined use of iodide and inunctions of mercury.

Dr. R. F. Weir said that he had had in the last ten years three cases of syphilis of the liver in which the diagnosis had been made only by exploratory incision.

Dr. B. Lapowski mentioned a case supposed to be one of syphilis of the liver. There was a history of syphilis, but the autopsy showed aneurism of the duodenum and of the hepatic artery. It was not sufficient to rule out syphilis because of the absence of a history of syphilitic infection, and the failure to find evidence of that disease on superficial examination. The examination should be most thorough. The treatment should be by mercurial inunction and should be begun early.

Intestinal Intoxication Occurring in Mucous Colitis in Young Children.—Dr. Henry Koplik read this paper. He said that the products of normal digestion when absorbed in excessive quantities might give rise to intoxications. Vertigo, headache, delirium, and even stupor and coma were symptoms of intestinal intoxication. The cases especially considered in the paper occurred in children from the fourth year up to the later years of childhood. As a rule, the children had been sufferers from chronic constipation and attacks of indigestion. Intervals of improvement and depression had dominated their previous lives. Such children after living for months on a carefully selected diet might, in a moment of indiscretion, take some article of food not easily digested, and as a result they would become so violently ill as even to make the physician anxious as to the outcome. There was a history in such cases of discharge of mucus from the bowel. The exact nature of mucous colitis was still very obscure. The intoxication often began with vertigo, even while the patient was in bed, and vomiting lasting for a day or two. There was usually a very full and bounding pulse, and in all cases there was more or less albuminuria. There was usually abdominal pain, though often it was not a prominent symptom. There was, however, no distention of the abdomen or pain on pressure. In one of the author's cases during a marked attack the breath had the odor of hydrogen sulphide, as did also the discharges of gas from the bowel. Masses of ill-smelling mucus were apt to be passed for days or weeks after such an attack. In the intervals of the attacks the children regained their strength and color, and the albumin and casts disappered from the urine. The constipation alone remained. The mucous discharges seemed to be accumulations of what under normal conditions would have been passed daily in inappreciable quantities. Ammonia was increased in any form of gastro-intestinal disturbance. Under normal conditions it was excreted in the form of urea. This form of intoxication seemed to be favored by the use of fat and nitrogenous food. The treatment should consist in rest in bed, the use of high enemata of salt solution, twice daily, the withholding of food by the mouth, and the substitution therefor of nutrient enemata. The latter should consist of two ounces every two hours of a solution of somatose, made by dissolving one drachm of somatose in eight ounces of cold water. Skimmed milk, cacao, cereals of all kinds, meat, and vegetables which gave little residue seemed to be the best form of diet. Baked potatoes might be allowed and also fruit juices. The attack could often be forestalled on the appearance of pallor and peevishness by giving a good dose of Carlsbad salt. He had not succeeded in completely eliminating the underlying condition.

Avoid Forcing Fat upon Infants.—Dr. A. Jacobi said that while albuminuria was present in most of these cases there was no œdema, the condition not being a true nephritis, but merely an intestinal intoxication. One must distinguish between two forms of intestinal disturbance, one occurring in the stomach and upper portion of the small intestine, and the other occurring in the large bowel. The cases referred to in the paper were chiefly the result of putrefaction in the colon. When this occurred, the fat and albuminoids underwent fermentation, and the result was the appearance of ammonia in the urine. It was the practice of modern pædiatrists to crowd a large quantity of fat into the bowel of the infant. The fat of even breast milk was not fully digested, but there was a difference between the fat of cow's milk and of breast milk. When the fat of cow's milk was crowded into children an acid fermentation would result. It was the common practice at the present time to fatten babies by increasing the proportion of cow's-milk fat, whereas it had long been his own practice to endeavor to reduce the proportion of such fat. Another unfortunate tendency was to overfeed babies with albuminoids. A certain quantity of cereal was not only digested, but was certainly required. There was not a better disinfectant for the intestine than starchy food in small quantities.

Dr. Henry Dwight Chapin said that these children often had enormous appetites, and although they ate wholesome food, they were apt to suffer alternately from constipation and diarrhœa. While the albuminuria and the casts were ordinarily temporary, if these attacks of intestinal toxæmia were allowed to recur frequently and continue for a long time there would ultimately result a parenchymatous nephritis. Regarding the use of nutrient enemata, he would say that while half an ounce or an ounce of fluid would often be well retained by the rectum, a larger quantity would be promptly rejected.

Dr. Thomas S. Southworth said that some children had an irregular or remittent temperature for weeks at a time, and in such cases there were usually unhealthy stools associated with a peculiarly persistent fetor. Regulation of the diet and the administration of salol would usually yield good results. Many of these cases terminated in bronchopneumonia. The lesion in the lung was simply an evidence of the infection of the intestine.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 10, 1901.

Edward K. Dunham, M.D., President.

A Note on the Prognostic Value of the Diazo Reaction in Phthisis.—Dr. F. C. Wood said that during the past year observations had been made at St. Luke's Hospital with the diazo reaction in two hundred and thirty cases. Of these patients, one hundred and ninety were still living and had presented no diazo reaction. Ninety per cent. had presented absolutely no reaction at any time, while the remaining ten per cent. had occasionally yielded a slight reaction. Some of these patients on becoming more severely ill had developed the reaction. These results corresponded very closely with those obtained in certain German sanatoria. Of the fifty-two patients who had died in the hospital, seventy-five per cent. had given a constant and strong reaction, and, if the persons dying from nephritis or hemorrhage before the process in the lungs had become advanced were eliminated, the percentage of fatal cases giving the diazo reaction was ninety. Of those giving a strong reaction extending over several weeks, forty were fatal within three months. They had noted some very strange fluctuations in the reaction. For example, it had been repeatedly observed that in damp or rainy weather a much larger proportion gave the diazo reaction. Any of the gallic-acid or tannic-acid preparations, as well as salol, creosote, and phenol, would inhibit the reaction. No connection had been observed between the strength of the reaction and the elevation of body temperature—in other words, the reaction seemed to indicate the extent of the tuberculous invasion of the lung rather than the amount of mixed infection. The speaker said that this test was being used in Germany as a basis for the exclusion from the climatic treatment in sanatoria of cases showing it.

Primary Endothelioma of the Peritoneum.—Dr. F. C. Wood presented this specimen. It had been taken from a woman of fifty-five, who had entered St. Luke's Hospital with a history of little use save emaciation and pain in the stomach. She was supposed to have a tuberculous peritonitis, and this diagnosis

had been thought to have been confirmed by the laparotomy to which she was subjected. No growth could be found in the intestine. The gall bladder was normal, and the lungs showed a few small metastases. As he had noticed an exactly similar condition result from the transplantation of colloid cyst adenoma to the peritoneum, a very careful search had been made, particularly of the ovaries. Some held that these growths were always primary in the intestinal mucosa; others that they originated in the lymph spaces of the subperitoneal lymphatics, but the question was yet an open one. It should be remembered that the endothelia of the peritoneum and of the ovary were both developed from the mesoblast.

A Case of Pneumococcus Endocarditis of the Tricuspid Valve.—Dr. Wood also presented specimens from this case. They had been taken from a woman of about thirty, who had entered the hospital with a serious lobar pneumonia on one side. Death had occurred in two or three days. Unfortunately no blood cultures had been made during life. At the autopsy both the tricuspid and mitral valves had been found covered with small vegetations. They did not look like ordinary vegetations of malignant endocarditis, and the process did not seem to have invaded the valve substance deeply. Cultures showed the presence of pneumococci. The vessels in both lungs contained ante-mortem thrombi, but no infarction of the lung was present. The liver showed extreme fatty degeneration. The kidneys showed a moderate glomerular nephritis of a rather acute type. The appearance of the vegetations was said to be quite characteristic of pneumococcus infection. The cases of endocarditis due to pneumococcus infection constituted twenty per cent. of all cases of malignant endocarditis.

Dr. James Ewing said that he had been deeply interested in this case of disseminated tumor of the peritoneum. It was almost identical in appearance with one presented to this society a few years ago by Dr. Jeffries. At that time the view had been expressed that this was probably a primary tumor of the peritoneal endothelium. At the last meeting he had himself presented some evidence against the view that these growths were endotheliomata. He had found a small tumor of the intestine of a carcinomatous type that had produced a very small lesion of the intestinal mucosa, and had rapidly reached the peritoneal coat, and was in the act of spreading out and producing these small masses. This had led him to think that the old pathologists had been right in believing that this was an example of colloid cancer secondarily involving the peritoneum. He did not think much could be learned from chemical examination of these cases. Without an extremely minute examination of the intestinal tract and of the pelvic organs as well, it was impossible for one to urge strongly that a given tumor originated from the endothelium of the peritoneum. Foreign authorities were strongly opposed to considering these as anything but growths of the intestinal epithelium.

Dr. J. H. Larkin said that he had always looked upon these tumors as carcinomata. On microscopical examination they seemed to have a very close relation with the intestinal epithelium. About two months ago he had studied a case in which the peritoneum had been covered with myriads of gelatinous tumors. After prolonged search he had found the gall bladder immensely thickened and holding four stones, and there was also one single metastasis into the liver of an adenomatous formation. The tumors in the peritoneum were gelatinous, just like those presented this evening. He also believed in classifying these as carcinomata.

Dr. Wood said that Dr. Ewing did not seem to take into consideration certain recent reports from Germany. A seach of the literature seemed to him to show that it was almost the rule for the authorities there to take the ground that these tumors originated in the endothelium of the lymph spaces. The case under discussion gave no definite evidence as to its origin.

Thrombosis of the Inferior Vena Cava.—Dr. O. H. Schultze presented this specimen, which had been taken from a woman of twenty-six years, who had been admitted to the City Hospital on January 18th. The history had been furnished through the kindness of Dr. Thayer, pathologist of the hospital. On December 18th she had been delivered of a child by a midwife, and was said to have had fever and discharge for several days afterward. On February 4th she had complained of pain in the left knee and thigh. An examination of the blood on January 26th had shown 11,250 white blood corpuscles and fifty-five per cent. of hæmoglobin. An examination of the urine showed it to have a specific gravity of 1.020, and to contain a distinct trace of albumin and many granular casts. On February 26th the blood had been examined by Dr. Thayer, and had given a positive Widal reaction in a dilution of one in twenty. The temperature chart showed an irregular remittent type of fever. The autopsy had been held at the morgue forty-two hours after death. The immediate cause of death had been a fibro-purulent peritonitis involving the entire surface of the peritoneum. An abscess in the upper part of the spleen, evidently resulting from infarction, had infected the peritoneal cavity. A similar purulent infarct was found in the lower portion of the spleen. These infarcts were surrounded by marked connective-tissue proliferation. The fact that the infection of the peritoneum had not occurred earlier was probably to be explained by the presence of a very dense capsule. An organizing thrombus was found in the inferior vena cava, extending from the right auricle down throughout the entire inferior vena cava, and into both common iliacs and both external and internal iliacs. The wall of the inferior vena cava was enormously increased by connective-tissue proliferation. Both kidneys showed areas of anæmic infarcts surrounded by very slight reaction. The uterus showed a marked thrombosis of all the veins with organization of the thrombi. The mitral valves showed an endocarditis verrucosa without purulent infiltration. In view of the Widal reaction having been present the intestine was carefully examined, but with negative result. Dr. Smith had made cultures from the central portion of the spleen, from the two infarcts, from the contents of the gall bladder, and from a nodule on the mitral valve. Colon bacilli were present in all these localities, and bacillus pyocyaneus was isolated from the nodule on the mitral valve. In view of the time intervening before autopsy no reliable conclusions could be drawn from this examination. The case was remarkable in the entire absence of œdema and hemorrhagic infarction or any disturbance of circulation, with the exception of the anæmic infarcts of the kidneys and the pyæmic infarcts of the spleen. From the evidence of advanced organization of the thrombus in the inferior vena cava from below the entrance of the hepatic veins to the origin of the deep epigastric, and the venous plexus of the bladder, vagina, and rectum, this occlusion must have been of considerable duration. We must suppose that the anastomoses between the deep epigastric and internal mammary, the pelvic plexus, and the hemorrhoidal through the portal system, and finally the azygos veins, were sufficient to take care of the return flow.

Dr. T. C. Janeway said that he had seen recently a case, in a man of fifty years, with extreme dilatation of the superficial abdominal and thoracic veins, the current in them being upward, in which there had been

apparent obliteration of the inferior vena cava. The patient was a physician who seemed to be perfectly well, and who stated that he had had this condition since childhood.

Dr. E. Libman said that he had recently seen a case of suppuration of the left ovary and tube, with slight œdema of both lower extremities. Death had occurred rather suddenly, and the autopsy had revealed embolism of the pulmonary artery and thrombosis of the inferior vena cava. The thrombosis had begun in the left iliac and had extended almost up to the diaphragm. It seemed to be the opinion of some authorities that the collateral circulation in these cases could be distinguished from that observed in portal thrombosis. In the latter there was more apt to be dilatation of the veins around the umbilicus, whereas in the former the veins in the sides of the abdomen were enlarged. In a number of reported cases there had been no œdema of the lower extremities. The case cited by Dr. Janeway might also have been one of (congenital) stenosis of the hepatic vein at its junction with the vena cava.

Dr. E. K. Dunham said that there was in the Harvard museum a dissection showing congenital absence of the inferior vena cava with venous return through the azygos. This vessel emptied into the hepatic vein after it had left the liver.

Two Cases of Hypertrophic Stenosis of the Pylorus.—Dr. J. H. Larkin said that our knowledge of stenosis in infants dated back to 1841, when Williamson had described such a case. Another case had been reported soon afterward, but nothing further had been heard about this condition until Hirschbaum, in 1888, had collected a series of cases that since then had received much attention. Up to the present time forty-six cases had been reported, and to these the speaker could add one. In only seven of the cases had the diagnosis been made during life, and of the four operated upon only one had terminated successfully. The first specimen presented had been taken from a male child, seven weeks old, weighing at birth six pounds and three-quarters. It had done fairly well for two weeks, and then the gastric pain and frequent vomiting had attracted attention. Death had occurred in the seventh week without the diagnosis having been made. In this, as in all the other cases examined but two, there had been found a hypertrophy of the circular muscular fibres. Microscopical examination in the present case had shown a marked increase in the connective tissue between the muscular fibres. The tubular glands of the stomach were entirely replaced by connective-tissue growth. This was the first case, he believed, in which this last condition had been found. In this connection the specimen taken from Dr. Meltzer's reported case was exhibited. Dr. Larkin also showed a transverse section of the pylorus taken from a man forty-six years of age. The musculature was entirely gone, being replaced by connective tissue. The speaker said that of the theories to explain congenital pyloric stenosis two were worthy of mention. One of these, the theory of Thompson, supposed that the stenosis resulted from an affection of the nerves supplying the muscles of the stomach. It was objected that the change in muscular tone could not produce a muscular hypertrophy, and certainly it could not account for the growth of connective tissue in the submucosa. The other theory presupposed the existence of an embryological defect.

Dr. Schultze reported an almost identical case. It occurred in a child dying at the end of six or seven weeks after birth. The vomiting had begun with the first nursing, and had continued persistently to the time of death. At the autopsy, the wall of the pylorus was thickened to 1 cm. The chief hypertrophy was in the circular muscular fibres.

Precipitation of Certain Proteids by Bacteria.—Dr. E. Libman presented a large series of culture tubes and plates, in illustration of the fact that most bacteria in the presence of sugar serum or egg albumen threw down proteid precipitates. The precipitation in agar tubes was evidenced by a whitening of the medium. The following topics were touched upon: (1) The variation in the occurrence of the precipitation by various bacteria in the presence of different sugars, in various strengths. (2) The usual absence of precipitation by staphylococci in the presence of one-tenth per cent. glucose. (3) The usual absence of precipitation by the typhoid bacillus in the presence of lactose in any strength. (4) The advantage of adding one-half per cent. glucose to serum agar for cultivating the gonococcus. (5) The absence of liquefaction of gelatin by certain peptonizing organisms in the presence of glucose. (6) The possibility of throwing out a coagulum in a serum by the addition of cultures of some bacteria in glucose bouillon, when the same result could not be obtained by adding cultures of the same organisms in ordinary bouillon. Dr. Libman was of the opinion that the media used in connection with this work would be employed largely for clinical diagnostic work, and eventually perhaps for the differentiation of species of bacteria.

Congenital Occlusion of the Duodenum.—Dr. Louise Cordes read a paper on this subject, and presented a drawing of the case reported. She had found fifty-six cases of occlusion of the duodenum besides the one reported in her paper. Total occlusions were more common than stenoses. The causes were numerous, the more important being errors of development, volvulus, ulceration, pressure from new growths, persistence of the omphalo-mesenteric duct, circulatory anomalies, and embolism of the superior mesenteric artery. The old idea that amniotic bands might cause strangulation of the intestine had been disproved. Some authors excluded volvulus as a cause when the stenosis occurred at about the middle of the descending limb of the duodenum, as twisting at this point was prevented by fixation of the gut by peritoneum. Of the fifty-seven cases reported there were atresia in forty-eight and stenosis in nine cases. The occlusion occurred most frequently near the opening of the common bile duct into the duodenum. In her own case there had existed, in addition to the atresia, an anomaly of the common bile duct, a branch of the same having been found leading into the dilated duodenum above the atresia. The child had vomited bile-stained fluid, and was found dead on the fourth day. The mucosa at the point of occlusion was smooth, showing no trace of cicatrization. The papilla was situated immediately below the atresia. This malformation, she stated, was most common in premature infants, and the majority of them died in four or five days. The occlusion was near the papilla in thirty-eight cases.

If Operative Technique be Perfect, can Sepsis Occur?—G. C. Barton emphasizes the fact that no physician should operate, or assist in operations, who attends contagious diseases or holds autopsies, or who is habitually handling pus cases; that no nail-brush should be used by two persons without an intervening sterilization; and that no person should be allowed to come into, or go out of, the operating-room after the abdomen has been opened, until it is closed again. The experience of most successful eastern operators has shown them that these rules are necessary to their success. This being true, no physician or surgeon has any right to risk a life by neglecting any of the precautions which have contributed to the success of other men.—*Northwestern Lancet*, April 15, 1901.

MANHATTAN DERMATOLOGICAL SOCIETY.

Stated Meeting, May 3, 1901.

WILLIAM S. GOTTHEIL, M.D., PRESIDENT.

Pityriasis Versicolor of the Palms.—DR. R. ABRAHAMS presented a woman with tinea versicolor limited to the palms. No case of this kind, other than that of Gottheil's, had been reported. Patches of various size and color had existed on the palms for a year and a half. At present, owing to cleanliness, the palms showed a superficial scaliness. Hyperidrosis of the hands was noticed in the summer. Examination of the scrapings by Dr. Gottheil showed the classical picture of microsporon furfur.

DR. GOTTHEIL said that, although the clinical aspects were not so typical as in his case, the microscopical picture was characteristic.

DRS. L. WEISS and A. BLEIMAN remarked that at present the case looked like eczema. The microscope decided the question.

DR. J. SOBEL advised painting the palms with Lugol's solution in order to bring into relief the pale and imperceptible lesions (Allen's test).

Prurigo.—DR. E. L. COCKS presented two cases of prurigo in native-born children, one a boy of eight, the other a girl of nine. Both had had urticaria from early childhood. At present there existed papules on the extensor surfaces of the limbs, some adenopathy, and upon rubbing the hand over the lesions the characteristic nutmeg-grater feeling was experienced.

DR. R. ABRAHAMS considered both to be cases of chronic urticaria. Sweating with pilocarpine was advised.

DR. J. SOBEL stated that neither case corresponded to his conception of prurigo. He missed the firm papules, the nutmeg-grater sensation, and the so-called buboes of the latter. To his mind, both were cases of chronic urticaria of the papular variety.

DR. KINCH considered both to be cases of prurigo mitis.

DR. L. WEISS advised the use of the term lichen urticatus or chronic lichen simplex for these cases. Both cases lacked the haggard anæmic look and the buboes of prurigo.

DR. OBERNDORFER said neither case looked like one of prurigo. There was absence of infiltration, and the character of the individual lesions was wanting. The adenopathy was not that of prurigo. He would call both lesions chronic papular eczema.

DR. GOTTHEIL remarked that the picture was not quite that of prurigo or of urticaria. He inclined toward a diagnosis of prurigo.

Eczema Neuroticum Vegetans.—DR. L. WEISS presented a woman with a symmetrical lesion of the lower limbs. There were irregular patches, with somewhat healed centres; the individual lesions were small, elevated papules simulating lichen.

DR. E. L. COCKS would diagnose lichen planis and eczema.

DR. OBERNDORFER said he saw no lichen, only an eczema.

DR. BLEIMAN looked upon the lesion as pruritus senilis and eczema.

DR. J. SOBEL considered it a mycotic eczema from its more or less circular form, its somewhat sharply defined edges, the healed centre, and its persistency. Such cases responded well to chrysarobin or formalin.

DR. R. ABRAHAMS called it parasitic eczema. Carbolic acid and a saturated solution of silver were recommended for treatment.

DR. KINCH remarked that the lesion was an eczema.

DR. GOTTHEIL said the papules were typically those of eczema.

Rosacea.—DR. L. WEISS presented a patient with rosacea of the cheeks. Stretching of the skin showed the capillary dilatation and circulation.

DR. GEYSER advocated the use of a negative galvanic needle inserted at right angles into the vessels.

Favus of the Nails.—DR. A. BLEIMAN presented this patient, a girl of twenty-three years. Lesions of favus were found on the scalp.

DR. KINCH remarked that the scalp showed but slight evidence of favus.

DRS. OBERNDORFER and GOTTHEIL would expect more destruction of hair in favus.

Acne Varioliformis.—DR. OBERNDORBER presented a case of probable acne varioliformis of the scalp and neck. Many of the lesions were atypical. The scalp also showed numerous bald areas.

DR. ABRAHAMS found two conditions: (1) Acne vulgaris, and (2) folliculitis.

DR. J. SOBEL saw no lesions of acne varioliformis. He found a combination of acne pustulosa and folliculitis abscedens.

DR. E. COCKS did not consider the case one of acne varioliformis.

DR. WEISS said it was an acne with folliculitis decalvans.

Resolving Syphilis.—DR. OCHS presented this case.

Pityriasis Rosea.—DR. A. BLEIMAN presented this lesion in an adult. Some regions resembled those of seborrhœal eczema.

Scabies.—Dr. Bleiman demonstrated the "continuous treatment" of scabies with Wilkinson's ointment. The patient had used six and a half pounds of ointment in five weeks.

Therapeutic Hints.

Ovarian Neuralgia.—

℞ Camph. monobromat..... gr. iss.
Pulv. capsici ..... gr. ij.
Confect. rosæ ..... q.s.
Ut ft. pil. No. i. Repeat as necessary.

For the Cough and Fever Early in Pneumonia.—

℞ Potass. citrat..... ʒ vi.
Spir. æth. nit.,
Tinct. opii camph... .....āā ʒ iv.
Sol. potass. citrat.....ad ʒ vi.
M. S. Dessertspoonful every three hours.

—HUGHES.

To Make Sick-Room Air Aseptic in broncho-pneumonia of children, vaporize:

℞ Phenol 20
Thymol 10
Benzoin 10
Alcohol..... 100
Water..... 860

—CARRIÈRE.

Gonorrhœal Vaginitis.—

℞ Methylene blue..... ʒ iiss.
Alcohol..... ʒ iij.
Potass. chlorate ..... gr. iij.
Water..... ʒ vi.
Apply by means of tampons to posterior vaginal fornix.

—*Texas Clinic.*

Lumbago.—

℞ Sodii salicylat ..... gr. x.
Potass. iod..... gr. v.
Ext. sarsaparillæ fld..... ʒ ij.
Aq. destil.....q.s. ad ʒ ss.
M. S. One dose, after meals.

—TIRARD.

Paralysis Agitans.—To dissipate symptoms give such drugs as hyoscyamus, duboisine, cannabis indica, arsenic, iron, and occasionally gelsemium and veratrum viride.—COLLINS AND MUSKINIS.

Habitual Constipation.—

℞ Sulphuris loti,
Potass. bitartrat.....āā ʒ i.
Pulv. sennæ fol..... ʒ iv.
Syr. rhei..... ʒ ij.
Syr. rhamni purshianæ ..... ad ʒ iij.
M. S. Teaspoonful morning and evening.

—*Texas Clinic.*

Furuncles.—

℞ Acidi salicylici..... ʒ i.
Pulv. amyli ..... ʒ i.
Lanolini..... ʒ i.
M. S. Apply several times daily.

In generalized furunculosis rub well in over the surface—

℞ Acidi salicylici ..... gr. xij.
Petrolati ..... ʒ i.

—Philipson.

Intestinal Dyspepsia.—When medicine must be given, I can think of no better prescription for intestinal dyspepsia with flatulence than the following:

℞ Pepsini pur.,
Pancreatin. ext.....āā 2 gm.
Pulv. carb. lig.,
Bism. subgal.....āā 4 gm.
M. ft. chart. xii. S. One before meals.

—W. A. Wells.

Hay Fever.—Local treatment and

℞ Zinci phosph..... gr. $\frac{1}{16}$
Quin. sulph..... gr. ij.
Ext. nucis vomicæ..... gr. $\frac{1}{8}$
S. One such pill before each meal.

—J. N. McKenzie.

Influenza of moderate severity in children:

℞ Sodii benzoat.,
Salol.,
Acetanilid.....āā gr. iss.
Caffeinæ..... gr. $\frac{1}{4}$
M. ft. chart. No. i. S. Every three hours.

—Sheffield.

Vesical Antispasmodic in prostatic hypertrophy:

℞ Tinct. bellad..... gtt. viiss.
Potass. acetat..... gr. xv.
Aquæ menth. pip.....q.s. ad ʒ i.
Dose to be taken between meals three times daily.

—Guitéras.

Vomiting of Pregnancy is said by a French physician to be benefited by thirty or forty grains of sodium bicarbonate.

Bronchitis with profuse purulent secretion:

℞ Ol. terebinth ..... ♏ v.
Mucilaginis ..... ʒ i.
Aquæ..... ʒ iij.
M. S. ʒ i. at dose.

When there is deficient secretion:

℞ Ammon. chl..... ʒ ij.
Potass. iod..... gr. xij.
Vini ipecac ..... ♏ lxxx.
Mist. glycyrrhizæ ..... ʒ iv.
M. S. ʒ i. at dose.

—*Medical Times and Hospital Gazette*, February 16th.

Arthritis.—Apply over the part, cotton soaked in a solution of ammonium chloride (ʒ i.) in warm water (ʒ x.).

In Moist Condylomata about the genitals apply equal parts of burnt alum and tannin.

Pruritus Vulvæ in Diabetes.—

℞ Acid. boric..... ʒ iss.
Sod. biborat..... ʒ iss.
Aq. destil..... Oij.
M. S. Apply freely.

—Lutaud.

One-Day Cure of Scabies.—The patient rubs for half an hour with green soap and hot water, then lies in hot water for remainder of the hour, applying soap. He then rubs in

℞ Sulphur flor..... 20
Potass. carbonat..... 10
Adipis..... 120

This is left on for twenty-four hours. The clothes are sterilized while the bath is being taken.—Hardy-Fournier.

Pulmonary Tuberculosis.—

℞ Guaiacol ..... ʒ iv.
Creosote..... ʒ ij.
Cod-liver oil ..... Oi.
Oil cinnamon ..... ʒ ij.
Oil bitter orange..... ♏ xxx.
or
Oil bitter orange..... ♏ x.

M. S. Teaspoonful three times a day for the first week, two teaspoonfuls during second week, three during third week, and four during fourth week. Continue latter dose if stomach remains unaffected; otherwise reduce to two teaspoonfuls three times a day.

—*Merck's Archives.*

Congestion of Prostate due to Gonorrhœa.—

℞ Tinct. aconiti..... ʒ i.
Tinct. gelsemii,
Antipyrin .....āā ʒ ij.
Ergotol ..... ʒ i.
Aquæ destil..... ʒ iv.
M. S. Dessertspoonful every two or three hours.

—Corson.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 18, 1901:

	Cases.	Deaths.
Tuberculosis	310	135
Typhoid fever	42	4
Scarlet fever	702	59
Measles	368	7
Diphtheria and croup	299	39
Smallpox	105	13
Chickenpox	64	0

Dosage in Chloroform Administration.—On the appearance of the report of the anæsthetic commission of the British Medical Association we pointed out, says the *Medical Press and Circular*, how very indefinite was its teaching and how serious was the omission of any statement as to the best method of administering chloroform. We are glad to see that Dr. Waller, F.R.S., has taken up the matter on the same lines, and has published a stringent criticism of the finding of the commission, dealing in the first place with the want of definiteness in many of its conclusions and then more especially with the absence of all guidance as to whether in the administration of chloroform the quantity given should be measured or not. "We are anxious above all," he says, "to know whether a method of administration, elaborated during the last twenty-five years from a crude device due to Junker and crudely applied to animals in every physiological laboratory, is or is not what it has been repeatedly claimed to be, on the strength of data published over the names of experienced medical practitioners, namely, a volumetric method for the relatively 'safe' administration of anæsthetics." There can be no doubt, we think, that whatever may be the case among

experts in anæsthesia, who by practice get to know pretty well what they are doing, among general practitioners the great question is to measure or not to measure, and on this point the commission, according to Dr. Waller, where it is not dumb is misleading. Dr. Waller sums up the report of the commission as follows: "What has the ordinary administrator of anæsthetics learned from this clinical inquiry? That chloroform is more dangerous than ether, but that as regards methods of administration, rate of use, methods of restoration, clinical evidence has not warranted any conclusion. That special circumstances may render the use of some anæsthetic or combination of anæsthetics both safe and easier than that of ether or nitrous oxide, but that no indications are derivable from the present inquiry as to the nature of the anæsthetic or combination of anæsthetics that it may be desirable to employ, with the exception of the A.C.E. mixture, which holds an intermediate place between chloroform and ether, but is more dangerous to males than to females. And the most important clinical conclusion is that by far the most important factor in the safe administration of anæsthetics is the experience of the administrator, and that in many cases the anæsthetization is of such importance and gravity that it is absolutely essential that an anæsthetist of large experience should conduct the administration, a condition not always easy to fulfil. Clinical experience has done its best, and this is as far as it takes us. The dosage is of the greatest importance."

A Modified Form of Schleich's Anæsthetic Mixture.—A meeting of the British Society of Anæsthetists was held on March 1st, Dr. J. W. Silk, the president, being in the chair. Dr. R. J. Probyn-Williams, in conjunction with Mr. Harold Barnard and Dr. R. J. Howard, communicated a paper on a modified form of Dr. Schleich's anæsthetic mixture. The composition of the mixture employed was that recommended by Dr. Wertheim, of Vienna, viz., chloroform, one part; petroleum ether, one part; and sulphuric ether, one part. It was pointed out that petroleum ether was now included in the appendix of the British Pharmacopœia, where it was stated to have a specific gravity of from 0.670 to 0.700, but that actually used in these observations had a specific gravity of only 0.643. Experiments were first made upon animals, and some of the tracings thus obtained were thrown upon the screen. With petroleum ether alone it was very difficult to kill the animal (a cat). The blood pressure fell slowly but steadily, the heart beat became more rapid, and the heart volume increased, owing probably to the rise in the venous pressure. These effects contrasted strongly with those produced when chloroform was inhaled. If the above-mentioned mixture was substituted for the petroleum ether, there was hardly any fall in the blood pressure noticed, until the inhalation was pushed to the extreme. In practice a special form of Skinner's frame was used. Thirty-four administrations had been undertaken, varying in duration from five to forty-five minutes. Induction was easy, free from struggling, and occupied on the average eight minutes. There were no excessive secretions of mucus or saliva, and no signs of circulatory failure or cyanosis. The anæsthesia, though sufficient, was light, and patients came round rapidly; relaxation was perfect. The pupils reacted as when A.C.E. was used; shallow breathing was not observed. So long as the mixture was given sufficiently freely, there were no serious after-effects, and sickness was much the same as in chloroform.—*The Lancet.*

Ancient Sanatoriums.—The most magnificent sanatorium of ancient or modern times was probably that group of edifices which sprang up, by degrees, around the temple of Æsculapius at Epidaurus. Pure air, charming mountain scenery, elaborate hotels and baths, gymnasiums, a stadion, a library and music hall, and the most beautiful theatre in the Grecian world were among the attractions which drew hosts of invalids and their friends to this resort, while the god himself, assisted by his satellites and his sacred serpents, appeared to the sick in dreams, and worked cures and miracles, which are attested by official records accidentally preserved to us. Year by year, since 1880 or thereabouts, new structures have been excavated, and the precinct exceeds in extent even that of Delphi and of Olympia combined. A good general description of the latest results of these excavations, and of the probable purpose of the various buildings, is furnished in two lectures by Richard Caton, M.D., on "The Temple and Ritual of Asklepios," delivered at the Royal Institution of Great Britain. Dr. Caton's point of view is that of an intelligent amateur who has repeatedly visited and examined the ruins and has availed himself of the latest authorities, including the treatise of Carvadias, published last year. As a physician his opinion is, of course, striking and valuable with regard to certain technical matters. The dormitories, he thinks, could not have accommodated more than four or five hundred patients. The *abaton*, a lofty and airy sleeping-chamber, its southern side being an open colonnade, "is singularly like the shelter balcony or Liege-halle now used in treating phthisis. . . . There can be no doubt that many of the sick benefited greatly by the rest, the pure air, the simple diet, the sources of mental interest, the baths, exercise, massage, and friction, and, in later days, by the actual medical treatment adopted. Surgery was also employed." In fine, the sacred precinct necessarily gave opportunities for scientific study, and in the lapse of time had its resources re-enforced by scientific methods from outside. Dr. Caton tantalizingly refrains from any speculation as to possible resemblance of the alleged cures to those of modern hypnotism or suggestion, nor does he compare the miracles with those of modern shrines. The preposterousness of some of these and of their method is slightly modified if we remember that the patient dreamed his head was cut off, etc., though the text is imperfect.—*Evening Post.*

The Practical Use of Vital Statistics.—Mr. Frederick L. Hoffman, Newark, N. J., writing on the above question, concludes that it is not going too far to say that in no time in the world's history have the people been housed as well, have they been nourished as well, and have they in all respects lived as long and as well as the majority of our people do at the present time. But the problem which confronts us in the twentieth century more than in the nineteenth is the enormous growth of our large cities and the immense aggregation of millions of people upon a small area, such as we find to be the case in Greater New York, Greater Philadelphia, and even Greater Newark. . . . To-day, more than at any time in the past, do people inquire into the health factors of a community and the conditions making for a healthy and a long life, and only in proportion as our cities and country sections hold out inducements in this direction and make clear beyond the shadow of a doubt that our State is healthy and advantageous from this point of view will we attract in the very near future the overflow of the intelligent and desirable population of New York and Philadelphia. . . . We have a State offering every variety of natural advantages—the seashore, the mountains, proximity to large forest areas, and even a lake country such as England itself has little more of beauty and attraction to boast of. You cannot extend the practical utility of vital statistics in a more benefi-

cent direction than by giving strong encouragement to the local health officers of our cities and towns, and to all our physicians practising in the different sections of this State. Just in proportion as we thus demonstrate the practical value of vital statistics to the people at large, shall we gain for our State an increasing degree of public approval, which is so desirable and so fully deserved.

Measures for Combating Plague in Penang.—Dr. T. S. Kerr, colonial surgeon, in his report of an outbreak of plague in Penang, thus describes some of the methods used to drive out the disease. The Island was declared infected on May 25, 1899, and measures were immediately taken (*a*) to prevent the disease being carried to other parts; and (*b*) to limit as far as possible its spread on the island. With regard to the former, the measures required by the Venice Convention were at once strictly enforced, and continued in force until July 31st. During this 34,800 passengers were examined before being permitted to leave the port. As to the latter (*b*), measures which had already been prepared in anticipation of an outbreak of plague occurring were at once rigidly enforced. Shortly these were as follows: (1) Engagement of additional sanitary inspectors, with the necessary disinfecting and cleansing staffs. (2) The cleansing and whitewashing, and where necessary the disinfection, under the supervision of the sanitary authority of every house in the native quarter. (3) The daily inspection of all lodging-houses, brothels, coolie depots, markets, and any specially crowded or dirty quarters. (4) Destruction of rats. (5) Arrangements for transport to hospital of those attacked, and segregation of those who had been in contact with the sick. (6) Increased hospital accommodation and staff at the quarantine camp. (7) Scrutiny of the dead bodies of persons of all nationalities by an apothecary, unless the death was certified by a qualified practitioner. (8) Disposal of the dead. All these precautionary methods were carried out to the letter, with the result that plague was quickly stamped out in Penang.

Malpractice with X-Rays.—The New York *Tribune*, Sunday, April 14th, quotes the following from the Paris dispatch to the London *Telegraph*: "The Roentgen rays have been the object of a legal decision by the civil tribunal of Paris. A woman, Mme. Maquaire, underwent treatment with them, with the consequence that her skin was badly seared, and her hair fell out, and she sued her medical adviser, Dr. Renault, for $1,000 damages. The defense was that a doctor is not responsible for failure of his treatment, or even accidents arising from it. This question of medical responsibility, which interests every man and woman all over the world, was greatly discussed before French law courts some ten years ago. The present state of the law is that a physician is not responsible for any mishaps or consequences of any kind arising from a reasonable course of treatment. He is not even responsible for consequences of what French law terms 'ordinary mistakes,' but he is responsible for 'gross mistakes.' The civil tribunal avoided deciding whether the treatment by Roentgen rays was a gross mistake, but founded its decision upon the fact that Dr. Renault runs an establishment called a 'Radiographic Institute.' In this capacity, says the tribunal, the doctor is really a tradesman, and equally responsible with any other tradesman for accidents arising from his action. The judge thought the $1,000 asked for was a very moderate figure, and awarded this sum, together with costs."

Prevention of Tuberculosis in Pennsylvania.—In a pamphlet written and recently published by Dr. Guy Hinsdale, an interesting account is given of this work, a part of which is as follows: "The Pennsylvania Society for the Prevention of Tuberculosis was the first to be organized in this country, at least with this particular end in view. It was organized on April 10, 1892, and incorporated in 1895. It has endeavored to educate the community in a knowledge of the true nature of consumption and the means now considered necessary to control or conquer this disease. The means by which this end is sought to be obtained are: By the publication and distribution of pamphlets, by constant efforts to induce those in influential positions to use their earnest efforts to prevent the spread of the disease, and by striving to obtain the requisite conditions whereby those early affected may be restored to usefulness, or for those far advanced the safeguarding that will prevent the communication of infection to others. . . . In caring for the tuberculous three special corporations are devoted to this purpose. The oldest of these, the Protestant Episcopal City Mission, has conducted for twenty-three years the Hospital for Diseases of the Lungs at Chestnut Hill, about ten miles from the centre of Philadelphia. . . . The Rush Hospital for Consumption and Allied Diseases was opened in 1892, and in 1895 occupied a site at Thirty-third Street and Lancaster Avenue, West Philadelphia. The Free Hospital for Poor Consumptives was organized in 1895 and incorporated in 1897. Its object is to give hospital treatment to the consumptive poor. It has not yet procured its own home, because all the money it has been able to raise has been expended for the pressing needs of cases which have presented themselves; it pays their board in existing hospitals in Philadelphia and elsewhere. These four organizations, expending their efforts in three different fields, supplement each other's work for the restriction of consumption. The Pennsylvania Society for the Prevention of Tuberculosis directs public attention to the principles underlying the nature of the disease, the reasons why a fight against tuberculosis is perfectly rational, and its extinction almost within our grasp. Its work is to teach, to encourage private and to urge public action."

Medical Education in the United States before the Foundation of Medical Schools.—Prior to the formation of medical colleges in North America, it was customary for young men desirous of learning "physic" to go abroad and study in the schools of Edinburgh, London, or the continent, if they had the means, and if they had not the "wherewithal" they would apprentice themselves for a term of years to some practitioner of repute in the colonies, and at the expiration of the term of their indenture to him begin practice on their own account. As there were practically no laws as to who could and who could not practise medicine, many poorly educated physicians and charlatans arose to feed upon the laity. It has been estimated that at the outset of the war for Independence there were upward of thirty-five hundred practitioners of medicine, of whom not more than four hundred had received medical degrees.—"History of Medicine in the United States," by Dr. Francis Packard.

Immunity to Yellow Fever.—This question has proved a vexatious one from a quarantine point of view, and has been subject to some modifications as knowledge has been gained in handling the disease. In the opinion of the writer, there is but one immunity to yellow fever, and that is gained by an attack of the disease. For practical purposes, however, and to promote commercial intercourse with the Gulf States, a period of ten years' residence in an infected zone is accepted as giving immunity to the disease, upon the principle that the person exposed should have yellow fever during that time if he is susceptible; and during

the past ten years, when some good certificates of immunity have been issued, in not one instance has yellow fever developed among these passengers after departure for the United States. The danger is from the conveyance of the disease occurring in non-immune passengers and crews of vessels while en route to uninfected ports and places. Cases have occurred in which there was a moderate rise of temperature, without special symptoms to attract attention, and the experience of the past season in Havana has but confirmed past experience as to the great difficulty in making a differential diagnosis in very mild cases of the disease. So far as maritime sanitation is concerned, however, experience has confirmed the fact that the five-day period of detention for yellow fever from last exposure is sufficient time. It has been demonstrated in several instances during the past season that seventy to one hundred hours will safely cover the period of incubation.—"Quarantine Defense of the Island of Cuba," by Dr. Arthur H. Glennan, U. S. M. H. S., chief quarantine officer for the island of Cuba.

Uniform Medical Legislation.—In the Chicago *Tribune*, March 10th, is a forceful article by Dr. Emil Amberg, who eloquently urges the need for steps to be taken leading to this desirable end. Dr. Amberg in part says: "It is admitted that we have too many medical schools and that we are in need of a greater number of good ones. It would be a wise step to close about three-fourths of the medical schools now existing, and to place the rest under rigid State control; or, what would be still better, to make them State institutions, as, for example, the University of Michigan Medical School, even admitting that some of the private schools are satisfactory. Many of the medical schools now existing are the property of corporations for the benefit of a few. Special privileges have been granted to these combinations. This should never have been done. That the existing conditions reflect upon the whole medical profession is easily understood, and it cannot be denied that the public in general should have more interest in a question which concerns every citizen. . . . The importance of the movement is recognized more and more every day by the medical profession, and the public will undoubtedly take a hand as soon as it understands the subject more thoroughly. The question is a comparatively simple one, and it can be dealt with more satisfactorily if the public at large interests itself in the same to a greater extent. A great problem is before the people of the United States. Its solution should not be delayed."

The Income of the Medical Profession in Berlin.—The Medical Chamber of Berlin and the province of Brandenburg has issued an interesting report on the subject of the income of the medical profession residing in that district. The Chamber is authorized to fix an annual sum, to be paid by every medical man, for the expenses of the Chamber and the support of distressed members of the profession. It had been decided that a uniform rate of 10 marks ($2.50) should be paid, and an additional sum by those earning more than 5,000 marks ($1,250). The Chamber has been informed by the income-tax officials that of 1,946 Berlin medical men under the jurisdiction of the Chamber 529 earned from 900 to 3,000 marks (from $225 to $750), 273 from 3,000 to 5,000 marks (from $750 to $1,250), and 785 more than 5,000 marks ($1,250), the largest income amounting to 295,000 marks ($73,750). It appeared that 107 medical men had no taxable income at all; the income of 250 could not as yet be ascertained. In the other towns of the province the proportions were similar to those found in Berlin, so that 4 per cent. of all the medical men had no taxable income, 26 per cent. had an income from 900 to 3,000 marks, 17 per cent. 3,000 to 5,000 marks, and 40 per cent. more than 5,000 marks. In 13 per cent. no reliable information could be obtained.—*Lancet.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended May 17, 1901:

		Cases.	Deaths.
Smallpox—United States and Insular.			
Arkansas, Prescott	May 8th	5	
California, San Francisco	May 4th to 11th	3	
Colorado, forty counties	April 1st to 30th	430	
Illinois, Chicago	May 4th to 11th	9

THE DIAGNOSIS AND SURGICAL TREATMENT OF PROLAPSED KIDNEY; WITH DEMONSTRATION OF A SIMPLE METHOD OF EXAMINATION FOR ITS DETECTION.[1]

By AUGUSTIN H. GOELET, M.D.,

NEW YORK,

PROFESSOR OF GYNÆCOLOGY IN THE NEW YORK SCHOOL OF CLINICAL MEDICINE, ETC.

My observations have led me to the following conclusions, viz.:

1. That prolapsed kidney is more frequent than is generally supposed.

2. That it is often not suspected, because it does not always give rise to symptoms directly referable to the kidney.

3. That frequently it is not discovered because, by the usual methods of examination, only an expert can detect it, unless the kidney is much enlarged or the subject is thin and the abdominal wall relaxed.

4. That palliative measures are of no avail and therefore useless and unwise if the degree of prolapse is sufficient to produce symptoms.

5. That lumbar fixation is the correct method of treatment when there is no contraindication; the operation being simple, devoid of risk, and successful when properly executed and the patient is given careful preparation and proper attention during convalescence, extending over a period of several months.

The purpose of this paper is to draw attention to certain symptoms, frequently ignored, that are presumptive evidence of prolapsed kidney; also to describe a simple method of examination for its detection, which, when once it is understood, will enable any one with ordinary skill to discover it, and also to describe a technique for its fixation that possesses some decided advantages.

Though very generally regarded as rare, prolapse of the kidney may be found in about twenty out of every hundred women presenting themselves for gynæcological treatment, or one out of every four or five. Of this number, fifty per cent. suffer in consequence sufficiently to require operation for its fixation. Of the remaining fifty per cent. those that have symptoms may be relieved in great measure by a properly adjusted abdominal bandage with pad. It must be borne in mind, however, that this is a very inefficient form of support, and it must not be expected that it will keep the kidney in place, or that it will effect a cure.

The term "prolapse" is employed because it seems to define the condition more definitely than "movable" kidney.

In prolapsed or movable kidney, the organ has been dragged down out of its position, and is between the peritoneum and the muscles of the back, its fatty capsule being elongated to accommodate its movements. The kidney is, therefore, still extra- or sub-peritoneal. This condition must not be confused with floating kidney, which projects into the peritoneal cavity, is covered by peritoneum, and has a pedicle covered by peritoneum, or a mesonephron. Floating kidney is very rare, and is always congenital. Prolapsed (movable) kidney is always acquired, and is much more frequent.

The right kidney is found prolapsed very much more frequently than the left, perhaps because of its situation immediately under the large right lobe of the liver which rests upon it. Both kidneys are depressed nearly half an inch by deep inspiration. Prolapsed kidney is much more frequent in women than men.

In an analysis of one hundred women taken at random at my clinic, there were twenty with prolapsed kidney. In two, both kidneys were prolapsed, and in one case the left kidney was prolapsed without the right. I have found the kidney prolapsed but once in the male, a private patient.

Causation of Prolapsed Kidney.—The cause of prolapsed kidney is largely a matter of conjecture. It is usual to expect it to occur more frequently in women with lax abdominal walls, or in those who have become greatly emaciated from some exhausting disease, because the chief support of the kidney is its surrounding fat, which is greatly diminished in these conditions. Yet I am inclined to regard the emaciation, so often observed in connection with prolapsed kidney, as caused by the digestive and nervous disturbances it provokes. Hence it is often rather an effect than a cause of the condition.

It is by no means necessary to anticipate finding a history of great emaciation following some exhausting disease before suspecting prolapsed kidney. I have often found it in women who were abundantly supplied with fat—in some considerably above the average, who had never had a period of emaciation—and, on the other hand, I have noted absence of prolapse in many women who were extremely thin.

While childbearing, with the consequent straining efforts during labor, and the consequent loss of flesh during lactation are to be regarded as prolific causes, it is a fact that prolapse of the kidney occurs quite as frequently in women who have never borne children and quite often in young girls.

In one case that I recall, the patient was fifty-two years old and had been married, for the first time, but eight months. The only possible cause for prolapse of the right kidney that was discovered was prolonged excessive retching and vomiting that always occurred when she was on the ocean. She had crossed many times and was invariably very seasick.

Hence, excessive vomiting and retching may be regarded as a cause, as well as strains and violent exertion of other kinds.

Severe attacks of whooping-cough may be mentioned as a cause for prolapsed kidney. I have had one case in which this was the only thing to which it could be attributed, the kidney being discovered out of position for the first time within a year afterward.

Symptoms.—Prolapsed kidney gives rise to the following symptoms, naming them as nearly as possible in the order of their frequency:

Digestive disturbances, usually chronic, manifested

[1] Read before New York State Medical Association, New York County Branch, April 13, 1901.

chiefly by persistent intestinal distention, with sometimes gastric irritability. Nervousness and restlessness, with sometimes insomnia. Unusual fatigue on exertion, particularly after standing or walking. Palpitation of the heart and sometimes vertigo. Epigastric pain, usually to the left of the median line, or over the region of the heart. Dragging pains in the loin extending to the groin and down the thigh, aggravated by long standing or walking, and usually relieved after assuming the recumbent position. Inability to rest comfortably or sleep on the left side when it is the right kidney that is prolapsed. Irritability of the bladder, more pronounced during the day and after standing or walking. This usually disappears (though not always) after resting for some time in the recumbent position. Jaundice, which is usually transient, due, no doubt, to temporary obstruction of the common bile duct. Pain over the region of the appendix, simulating chronic appendicitis. Pain referred to the ovarian region, which is very misleading in the absence of other symptoms directing attention to the kidney. Acute attacks of pain resembling renal colic, which come on suddenly and subside as quickly. These attacks are infrequent and are, no doubt, due to obstruction of the ureter from flexure upon itself or kinking, or perhaps pressure upon the ureter by accumulation of fæces in the bowel or extreme gaseous distention.

Slight prolapse of the kidney below the normal plane may exist without producing symptoms and without being suspected. But any considerable deviation from the normal plane must of necessity produce digestive disturbances at least, owing to proximity of the kidney to and connection with the duodenum. The disturbances produced by prolapsed kidney are usually in proportion to the degree of misplacement and the length of time that it has existed. No doubt the size of the organ has much to do with the severity of the symptoms.

It is a fact worthy of serious consideration that prolapsed kidney often exists unsuspected, because the symptoms it most frequently gives rise to are such as are not generally recognized as being caused by it. Patients are not infrequently kept under treatment for months for so-called nervous dyspepsia and nervous prostration, without benefit and without the least suspicion of the real cause of the condition, the removal of which, by fixation of a prolapsed kidney, is invariably followed by immediate relief.

Chronic digestive disturbance is by far the most frequent symptom of prolapsed kidney, and when it is manifested by a persistent intestinal distention that is not relieved by the usual methods of treatment, it is most significant.

I recall a case sent to me because of a fibroid tumor of the uterus, which illustrates how easily a prolapsed kidney may exist unsuspected unless a general, thorough physical examination of the patient is made. This patient persisted in the belief that she was pregnant, because her abdomen was so much enlarged, though she was fifty-one years old, and admitted the enlargement was not constant. Her physician had, at her request, curetted the uterus so as to be sure the uterus was empty, because she did not wish, at her age, to have her first child. This did not satisfy her. She still persisted she was pregnant.

The fibroid with the uterus only half filled the pelvis and did not press unduly upon any important organ. I decided, therefore, that it was not sufficient to account for her symptoms, so looked for the cause elsewhere, and found the right kidney prolapsed below the level of the umbilicus. Abdominal distention was the only prominent symptom, and there was absolutely nothing else to direct attention to the kidney. An abdominal bandage with pad adjusted so as to furnish some support to the kidney gave her immediate partial relief, and she became finally convinced of her error regarding pregnancy. When she makes up her mind to have permanent relief, I shall fix the kidney and shall ignore the uterine tumor, which at her age may be left undisturbed, unless it begins to give trouble.

I have had several cases sent to me by physicians for operation, because they thought they had detected some inflammatory lesion of the tubes or ovaries, the symptoms apparently bearing them out in this diagnosis, because of persistent pain referred mainly to the right ovarian region, and I have discovered prolapsed kidney as the cause, the tubes and ovaries being perfectly normal.

One of these cases that I recall is very instructive and illustrates the immediate good result of fixation of the kidney when it is needed.

The patient was sent to me by her physician, out of town, with a note stating that he had diagnosed salpingitis or a pus tube, and he sent her to me for operation. She had gone down in weight from one hundred and thirty-five pounds to ninety-five, was greatly emaciated, and so weak she could not walk without assistance or support. She suffered continual pain in the right ovarian region and backache. There was considerable abdominal distention, with so much gastric disturbance that she could not bear anything on her stomach. The ride to the city on the train made her as seasick as on an ocean voyage, and she reached my office in a very much exhausted condition. I could discover nothing abnormal in the pelvis except an old laceration of the cervix and a very slight enlargement of the right ovary, which I find not infrequently associated with this condition. The right kidney was prolapsed below the umbilicus.

I operated three days later, repairing the cervix and fixing the kidney in position. All her symptoms disappeared from the time of the operation, most noticeably the gastric irritation, and she began to take food with relish and retain it, and in three weeks, when she left the hospital, she had gained six pounds. She has continued gaining and improving, and now, six months after the operation, she weighs as much as she ever did, and is in perfect health.

Pain referable to the kidney region is a most infrequent symptom of prolapsed kidney. In fact, most frequently the symptoms are what may be termed "reflex," which is perhaps the chief reason that this condition is so often overlooked. Pain, when present, is not, as a rule, very acute, but more of a dull aching, or an indescribable feeling of discomfort. Cases that have acute attacks of pain are rare.

Diagnosis.—A careful, thorough physical examination should be made in all cases presenting any of the above symptoms, and if nothing is discovered at the first examination, a second and a third similar examination should be made after one or two days' interval. This is important, since not infrequently great abdominal distention or a full colon may prevent the discovery of a prolapsed kidney that can be easily made out when this is removed. In the interval, of course, laxatives and copious enemata should be given to clear out the bowels. Another cogent reason for repeating these examinations is that frequently the patient will be nervous at the first examination, and in consequence there will be an unusual rigidity of the abdominal muscles that will prevent satisfactory palpation. Another reason for this abdominal rigidity is a sore, sensitive condition produced by the dragging of the prolapsed kidney. In these cases, it is best to defer examination and withhold a final decision until the soreness has subsided. To overcome this, these patients should be put to bed and kept quiet for a few days, and the examination should be made at their home before they have been around on their feet and gotten the kidney out of position again.

It is by no means easy to make out a prolapsed kidney by the usual methods of examination that have been described by different writers, unless one has given the subject special attention and has become more or less expert. The gynæcologist who, by constant practice, has become an expert in abdominal palpation should experience no difficulty, but the general practitioner, who perhaps is more frequently called upon to make a diagnosis of this condition, will not find it easy.

If the examination is attempted with the patient in the reclining position, the kidney will slip up into position under the ribs, and it is difficult sometimes to dislodge it. Therefore, as a rule, the examination should be made with the patient standing, and with the body inclined slightly forward so as to relax the abdominal muscles.

The method of examination that I have found most uniformly satisfactory and recommended as simplifying the detection of prolapsed kidney, is as follows:

The clothing is loosened about the waist, the corsets are removed, and the undergarments that are suspended from the shoulders are rolled up under the breast, exposing the ribs below the level of the ensiform cartilage, while the skirts are drawn down below the level of the crest of the ilium. The patient is directed to hold up the upper garments with the right hand and to support the skirts with the left to keep them from dropping off. This gets her hands out of the way. She is then placed with her back to the edge of a table for a brace, or against the wall or a door, but she must not be permitted to lean back against it. The legs must be perpendicular to the surface upon which she stands. She is now directed to incline her body slightly forward by flexing it upon the pelvis. If the abdomen is unduly rigid and is not sufficiently relaxed by this position, additional relaxation may sometimes be secured by directing the patient to bend the right knee and rest the toe of that foot only on the floor, throwing the weight mainly upon the left foot. The examiner sits in front of her a little to the right. He grasps the right loin with his left hand, with the four fingers behind the right lumbar region and the thumb in front just below the border of the ribs, as shown in the drawing. The patient is now directed to take several deep inspirations and to expire to the extreme limit. When expiration is complete, he presses the thumb well into the abdominal wall under the ribs, depressing it as much as possible so as to reduce the space between it and the fingers posteriorly. If the kidney is out of position, it must be below his thumb, and he can feel the kidney slip under his thumb if it is pushed up into position. With the left hand flat against the abdomen, as represented in the drawing, he draws the relaxed abdominal wall downward and depresses it by pushing with the fingers inward, then upward. If he succeeds in getting the fingers under the kidney, it will be pushed up against and then under the thumb by this manipulation. It will require some little practice to maintain the necessary depression by the thumb, while attention is diverted to the manipulation of the other hand. Sometimes it will be possible to engage the kidney between the tips of the fingers below and the thumb above, before it is pushed up into place, and by manipulation outline it distinctly. This is possible, however, only when the abdominal wall is thin or relaxed.

When the abdominal wall is thick or cannot be made to relax sufficiently when the patient is standing, she must be made to recline on the back with the right leg flexed and supported. The examination is made in the same manner in this position also; but, as a rule, the kidney will slip back into position as soon as she lies down and it is not always an easy matter to dislodge it. She is made to take several deep inspirations and to expire to the limit, and, as she expires, the thumb is pressed suddenly well up under the border of the ribs. If this manœuvre is not successful in dislodging the kidney, she is directed to cough hard several times.

If it is the left kidney that is to be sought, the same manipulations are employed but the hands are reversed, the examiner sitting to the left of the patient.

The relation of a prolapsed kidney to the median line is by no means always the same. Sometimes it will be found near the umbilicus and sometimes down in the iliac fossa, in the region of the appendix. Hence manipulations for its detection must extend over the whole region between the lower border of the ribs above and Poupart's ligament below and from the median line to the lateral border of the abdomen.

When the kidney is pushed up into position, the patient usually experiences a sensation of faintness or nausea, but this is not invariable. Manipulation of the prolapsed kidney is not generally very painful, unless for some reason it is unduly sensitive.

Fig. 1.—Author's Method of Palpation for the Detection of Prolapsed Kidney.

Prolapsed kidney must be differentiated from distended gall bladder, tumors of the pylorus, tumors of the omentum, growths in the intestines, particularly in the ascending colon, and impacted fæces.

Prolapsed kidney is perhaps most often mistaken for a distended gall bladder. The chief characteristic of prolapsed kidney is the facility with which it may be restored to its proper position, particularly when the patient is on the back, whereas a distended gall bladder may be pushed upward but cannot be made to disappear backward. Pressure upon a distended gall bladder usually elicits considerable pain. The prolapsed kidney does not appear as a visible tumor even when the patient is on her back, unless it is unusually large. The distended gall bladder is frequently a distinct tumor, particularly when the abdominal wall is relaxed, as when the patient is on the back. The range of mobility of a prolapsed kidney is much greater than that of a distended gall bladder.

Tumors of the pylorus are nearly always associated with obstruction, and it is seldom possible to make them disappear by palpation. When they are displaced under pressure, they move directly upward, instead of upward and backward as does the kidney.

Tumors of the omentum in this location are nearly always associated with malignant disease elsewhere in the abdomen, of which there is evidence.

Growths in the colon, especially those near the hepatic flexure, more nearly simulate the kidney. Repeated examinations in different positions, and inflation of the colon with gas, should clear up the diagnosis.

Impacted fæces making a tumor in this region are removed by clearing out the bowel.

Treatment.—If the degree of prolapse is not sufficient to give rise to symptoms, and if the physical condition of the patient is such as to render exaggeration

of the prolapse improbable, no treatment is required, but the patient should be cautioned to avoid strains of all kinds that would tend to increase the displacement.

In these cases, a properly fitting corset will furnish all the support required, and this should be worn continually during the day, particularly about the house. The straight-front corset now in vogue is, I think,

Fig. 2.—The Author's Universal Retractor.

the best form, since it does not, like others, tend to crowd the abdominal viscera down below the waist line.

When the prolapse is sufficient to produce symptoms not sufficiently urgent to demand operation, or if the patient does not favor it, these symptoms may be relieved by a properly adjusted abdominal bandage with pad for support. It must be understood, however, that this will never lead to a cure of the local condition, and it must be worn continually, except when in bed. Such support does not even replace the kidney or hold it in position. It affords sufficient support only by pressure upon the overlying intestines to prevent the kidney, under favorable conditions, from dragging down to its extreme limit. When it is realized that a prolapsed kidney cannot be held in place when the subject is in the erect position, even by deep pressure with the thumb or fingers under the ribs, the inefficiency of any form of abdominal support is readily appreciated.

Prolapsed kidney cannot be cured except by fixation with sutures, and be the displacement ever so slight, if sufficient to be detected it will, in time, become exaggerated. This is unavoidably true, owing to the necessities of woman's environment.

The indication for operation is a sufficient degree of prolapse to give rise to symptoms that cause positive discomfort or interference with the health of the patient. There is one class of cases, however, in which operation is urgently demanded and in which delay endangers the life of the patient, viz., those who suffer attacks of acute pain denoting obstruction or strangulation of the ureter.

The operation is not one of sufficient gravity to cause any one to shrink from it. It is comparatively safe, is not mutilating, and the result is highly gratifying. It consists of an incision in the lumbar region through the skin and fat only, down to the muscles, which are separated in the direction of their fibres, exposing the fatty capsule of the kidney. This is opened, the kidney pushed up into the wound and attached by sutures.

The patient should be prepared as carefully as for an abdominal section. This is important, both to secure asepsis and primary union of the wound, and to avoid retching and vomiting following anæsthesia, which would tend to strain or loosen the attachment of the kidney.

The general preparation should consist in a thorough clearing out of the intestinal tract, and in those cases in which gastric and intestinal disturbances have been prominent symptoms the patient should be kept quiet in bed for three or four days immediately preceding the operation, and should be placed upon a restricted, easily digestible diet. Rest in the recumbent position, by replacing the kidney, will do much to relieve the irritability of the stomach and obviate vomiting after the operation.

The patient is placed upon the table on the left side with the left arm drawn back behind, as in the Sims position, with the thighs flexed and the pelvis tilted forward so as to bring the right lumbar region uppermost. A firm, thick roll is paced under the left side so as to press into the abdomen, between the lower border of the ribs and the pelvis. This increases the distance between the last rib and the crest of the ilium on the right or upper side, crowds the abdominal viscera upward, and usually replaces the kidney, thus making it easily accessible.

The position is reversed when it is the left kidney that is to be fixed. When the operation is to be done on both sides at the same time, the patient is placed flat upon the abdomen and chest, and the roll is placed transversely under the abdomen.

The field of operation is given the same careful preparation as is employed for abdominal section—the surface being scrubbed and shaved and afterward surrounded by sterile towels.

Technique of Nephropexy.—An incision is made with the knife parallel to the spine, close to the outer border of the erector spinæ muscle, from just below the last rib downward for about three inches. This incision divides the skin and fat down to the superficial fascia. Retractors are now inserted and the margins of the wound drawn apart. The vessels divided are small and seldom require forci-pressure or ligature. The pressure of the retractors will, as a rule, suffice to control the bleeding. The fascia is now divided with the knife to the extent of the incision above and below, exposing beneath the fibres of the latissimus dorsi and the posterior border of the external oblique muscles. The knife is now laid aside and with the curved, blunt scissors, closed, the successive layers of muscles are separated in the direction of their fibres. As each layer is separated, the retractors are reinserted so as to include their margins and draw them apart. The erector spinæ is separated from the lumbar fascia in the same manner and beneath is encountered the outer border of the quadratus lumborum. Usually this can be retracted toward the spine and the

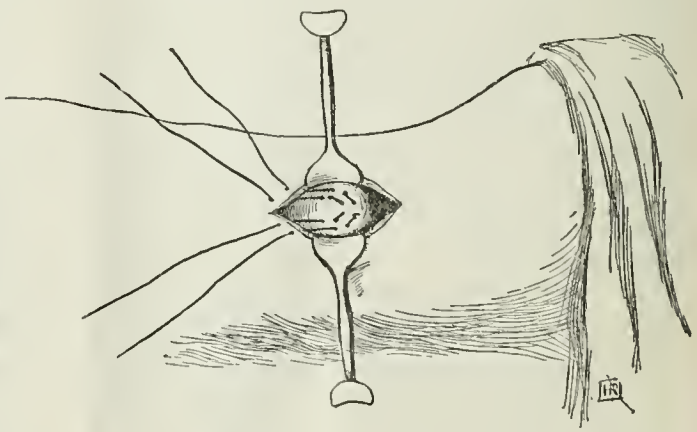

Fig. 3.—Author's Method of Inserting Fixation Sutures.

circumrenal fat is exposed beneath. The retractors are now made to include all of these structures, and they are drawn upon so as to spread the opening as much as possible.

The fatty capsule is opened with the scissors and the finger inserted for exploration and location of the kidney. It is best to open the capsule high up and well over toward the spine. If the kidney has

not been crowded up into position by the pressure of the roll beneath the abdomen, an assistant is directed to pass his hand under the covering, grasp it through the abdomen, and push it up into place so it may be reached by the finger. The fatty capsule is then divided to the extent of the wound, its margin on each side being grasped with a pair of sponge-holder forceps and drawn out. The kidney is caught with a pair of tenaculum forceps and carefully drawn up into the wound, taking care not to drag on it enough to cause them to tear out. The lower border of the kidney must be exposed in the lower angle of the wound.

With a quarter-curved needle, threaded with silkworm gut, two sutures are introduced through the lower half of the kidney structure in the manner indicated in the drawing, about half to three-fourths of an inch apart. The needle is first inserted rather superficially on the lateral surface of the exposed kidney from above downward in a direction somewhat oblique to its long axis; then it is inserted deeply through the kidney structure transversely and again superficially on the opposite lateral surface from below upward. As each suture is inserted, the ends are grasped with pressure forceps. The object of inserting the suture in this manner is to distribute the strain upon the central or transverse insertion, and lessen the chance of it tearing out.

The kidney is supported in the wound by means of these two sutures, and the finger is swept around it to separate it from its fatty capsule. The redundant fat drawn out is trimmed off on a level with the bottom of the wound.

The free ends of each silkworm-gut suture are now threaded into a needle, and carried through the margin of the fatty capsule and the muscular structure from within out and brought out on the skin surface. The ends of the upper suture are carried through the muscles and skin as high up as possible near the upper angle of the incision, and the other only a short distance below the first, as shown in the drawing. Thus, when these sutures are drawn upon and tied, the kidney is forced up under the border of the rib. Before these sutures are tied, the retractors are removed, and the wound is flushed with warm sterile decinormal salt solution.

A strip of several layers of sterile absorbent gauze is now inserted along the free border of the kidney and brought out at the lower angle of the wound to provide drainage and excite plastic inflammation. The sutures are then drawn up firmly, but not too tightly or they might cut through the kidney structure, and are tied over a strip of several layers of gauze, folded half or three-fourths of an inch wide, along the length of the incision. Thus this strip of gauze is interposed between the knot and exposed portion of the sutures and the skin margins of the wound, forming an elastic support for the sutures and preventing them from being tied too tightly or from cutting through the skin.

If these two sutures are not sufficient to close the wound at the bottom, one or two catgut sutures are inserted through the skin and superficial muscles only and tied.

The dressing consists of an abundance of loose absorbent gauze and over this layers of absorbent cotton held in place by broad strips of adhesive plaster. An obstetric binder is applied over this, with a pad under it on the right side of the abdomen as a support for the kidney.

The patient should be confined to bed for three weeks. The gauze drain is removed on the third or fourth day, and a fresh dressing applied. The sutures are removed at the end of two weeks, the patient being kept in bed a week afterward.

The position of the patient while in bed is not unimportant. She must be restricted to the recumbent position, and should not be permitted to sit up or rise up in bed. If she turns on her side, it should always be on the side of the attached kidney, since turning on the opposite side would cause the kidney to drag on its attachment.

As a precautionary safeguard, an abdominal support should be worn for two or three months, and the patient should be cautioned to avoid strains of all kinds for at least a year.

2030 Broadway.

THE CLIMATE OF LONG ISLAND.[1]

By LE GRAND N. DENSLOW, M.D.,

New York,

Fellow of the New York Academy of Medicine.

A brief consideration of certain general meteorological influences, to which the climate of Long Island is mainly due, will give a better understanding of the subject in hand.

"The prevalence of westerly winds is the most obvious and permanent feature of the atmospheric circulation in the middle latitudes of the globe. This movement of the air masses in a measure communicates the conditions of the continental interior to the eastern coasts, while in the same manner the influence of the ocean is extended well inland along the western coasts. During the winter heat is lost from large land surfaces by radiation much more rapidly than it is gained from the oblique rays of the sun; and consequently, in high latitudes regions of intense cold are found within the continents. Over the ocean, on the other hand, radiation proceeds slowly as compared with the rate on land surfaces, while vast quantities of heat are gained from equatorial currents. In summer the increased heat received from the sun is absorbed more rapidly by land than by water, so that the thermal relation between continents and oceans is the reverse of that which obtains in winter."[2]

This explains the apparently contradictory fact that our land winds are hot in summer and cold in winter, while those from the ocean are cool in summer and warm in winter.

Long Island is situated between longitude 72° and 74° and latitude 40° and 41°, extending almost east and west from New York Bay to Montauk Point, for about one hunded and twenty miles, lying between the great arm of the sea, Long Island Sound, and the Atlantic Ocean.

"The coast line of Long Island is strikingly irregular.[3] Along the north shore are eight deep and extensive bays, which form excellent harbors, and also a large number of inlets, most of which are navigable. The east end of the island is penetrated by Great and Little Peconic bays, to a depth of twenty-two miles, while the south shore, west of Southampton, for about ninety-five miles, consists of an intricate series of shallow creeks, partly surrounded by salt marsh, tributary to Shinnecock, Moriches, Great South, Hempstead, and other bays, which are divided from the ocean by long sand beaches (from one to five or six miles distant from the mainland), intersected in places by narrow inlets. Shelter, Robbins, Plum, Gull, and Gardiner's islands, which form part of Suffolk County (Long Island), New York, do not differ from Long Island essentially in physical or geological characteristics. Long Island, as a whole, is comparatively low and flat, but throughout the central part is a range of hills extending from Bay Ridge northeasterly to Ros-

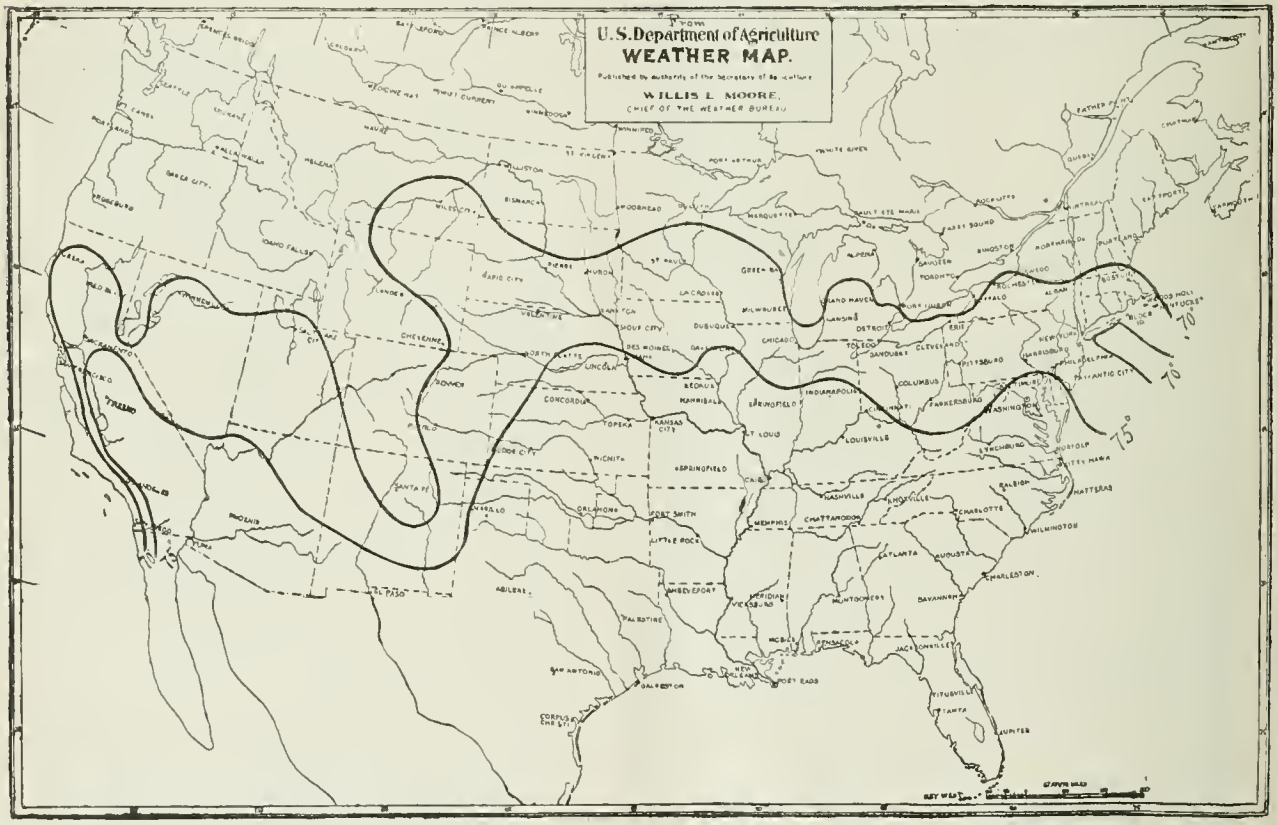
[1] Read before the section on medicine of the New York Academy of Medicine, April 16, 1901.

[2] E. T. Turner: "Climate State of New York." Weather Bureau, 1896.

[3] F. J. H. Merrill: "Geology of Long Island." Annals New York Assoc. of Science, 1884.

lyn, and thence continuing to Montauk Point in a series of elevations, the more important of which are known as West, Dix, Comac, Bald, and Shinnecock hills. The average height of this chain is about 250 feet; but at some points it is much greater. Harbor Hill, at Roslyn, is 384 feet above tide; Jane's Hill is 383 feet high; Renland's Hill has an elevation of 340 feet, and Wheatly Hill is 369 feet above the sea. There is also, along the north shore, an elevation which usually follows the contour of the numerous deep bays and inlets, varying in height from 30 to 200 feet, and almost continuous from Astoria to Orient Point. These two ranges of hills are the result of glacial action."

"South of the backbone, as the central range of hills is called, the surface is nearly level, gently sloping southward in an unbroken gravelly plain; while between this ridge and the north shore is a second plain, with an elevation of 50 to 100 feet, and especially noticeable between Port Jefferson and Riverhead. From



Lines show regions having same mean temperature during July. Line on Long Island drawn by author.

many of the deep bays on the north shore valleys extend through the hills in a southerly direction. There are thirty of these depressions, averaging about 25 feet in depth, usually occupied by small streams, most of which flow southward."

"There are no important lakes or rivers now on Long Island, but there are numerous ponds of clear, cool water, without visible inlet or outlet. The existence of these ponds depends on the fact that in the stratified sands of the island, which are underlain by clays, a uniform water-level, or plain, exists, which rises northward from low tide level on the south shore, at the rate of 12½ feet per mile. Wherever a basin has been excavated below the surface of this plain, it would necessarily be filled by these subterranean waters, which, by their constant percolation through the sand, would remain pure and clear, without material or sudden change of level under average conditions. The largest of these ponds is Lake Ronkonkomo, which is three miles in circumference, and has a maximum depth of 83 feet."

The geology of the island is comparatively simple. The greater part of it consists of gravel, sand, and clay, also along the south shore and to some distance inland glacial sand, gravel, and boulders. This gravel forms the soil of the pine lands of the southern and eastern portions.

"On Hempstead plains the wells are dug from 60 to 120 feet deep, through beds of gravel and sand, before water is reached, which is a little above the level of the ocean. The wells gradually decrease in depth thence to the shore."[1]

Temperature.—The temperature conditions which prevail on Long Island differ to a considerable extent with locality. The eastern end and south shore are the coolest portions in summer—July mean 68° to 70°. The north shore July mean is 72°, while the western end is about the same temperature as New York City—July mean 74° and January 31°. The winter temperature is slightly warmer at the eastern than the western end. A better idea of the marked difference in climate between the east end and south shore and the extreme west end is gained by following their respective isothermal lines, or lines drawn through those regions having the same mean temperature during the month of July:

"The line of 70° passes from the Great Lakes over northern New York, through New England nearly to the coast, turns southwest and appears over eastern Long Island. It then passes directly eastward over the Atlantic Ocean to northern Spain, through central France, Austria, central Russia, and Siberia; passes over Japan at the 20° of latitude, across the Pacific Ocean to central California, follows the 120° west; northward well into British America, then turning southeast toward the great lakes and northern New York.

"The line of 74° for July passes from Brooklyn and neighboring north shore, directly southward over the ocean, until opposite Virginia (representing the New Jersey coast); thence slightly south and east to Morocco, in north Africa, where it turns northward to France; thence passes through southern Europe (north

[1] Mather: "Natural History of New York," 1843.

of the Italian peninsula) to the Black Sea through central Asia at latitude 50°, and near the coast turns southward to Japan. Diverging somewhat from the isotherm of 70° in its course over the Pacific, it touches America in southern California, follows the Rocky Mountains northward to British America, and then takes a southeasterly direction to the Great Lakes and New York." [1]

The influence of the ocean upon the climate of Long Island can best be given as described in the Eighth Annual Report of the New York Weather Bureau:

"Owing to the general eastward drift of the atmosphere throughout the year, the effect of the ocean upon the temperature of the Atlantic States is, under normal conditions, derived almost entirely from a restricted portion of the water surface contiguous to the coast. The air flowing toward low-area storms over the land may, however, occasionally be drawn from the region of the Gulf Stream, whose warmest axis is about three hundred miles from the coast of this State (New York). The stream at this point has a total width of three hundred miles (the width of the surface is considerably less), a mean temperature for the year of over 73°; and summer and winter temperatures of about 80° and 70° respectively in the latitude of New York. Notwithstanding the fact that cold or polar currents exist on the landward side of the stream, it is stated by Captain J. E. Pillsbury, U.S.N., that if the prevailing winds in New England in winter were southeast instead of northwest, the climate would be equal to that of the Azores Islands, mild and balmy. The current is in its place, ready to give off heat and moisture to the air, but the erratic movement of the winds may deliver this heat and moisture at unexpected times and seasons, and thus give rise to the erroneous belief that the Gulf Stream has gone astray. The writer has met with no investigations of the meteorological side of the question, and only the general statement can be made that, with a special distribution of pressure, extensive easterly wind systems may bring from the Gulf Stream to the coast quantities of heat sufficient to modify our climate considerably during brief periods."

"The nearest approach to a true maritime climate within the territory of New York is to be found at the eastern extremity of Long Island. The temperature conditions of this region may be represented without much error by the average mean temperature monthly values obtained at Block Island, twenty miles due east. On this account all statistics obtainable from Block Island which are included in the tables used in this paper may be read as coming from the eastern end. Records from this part of the island are sadly meagre. The midsummer mean temperature is very nearly that of Malone, at the northern boundary of the State, while the temperature for January is between those of New York City and Washington. The equalizing effect of the water is thus very appreciable, although far below that exerted in the open ocean, or on the western shores of the continents. A comparison of the normal temperatures of Block Island for the spring and autumn with those of stations in New York plainly shows the effect of the ocean in retarding the progress of the seasons. This averages for the eastern extremity of the island twelve days later than the main portion of the State. This condition is less and less marked in passing from the eastern to the western portion of the island. It has been shown that the average retardation of maritime as compared with truly continental climates is from twenty to twenty-five days."

"The sea breeze is an important feature of the summer weather along the south shore, tending to reduce the range of temperature by moderating the mid-day heat. It reaches the shore about the middle of the forenoon, or a little earlier, with a velocity of ten or fifteen miles per hour, and produces a marked and agreeable depression of temperature, with diminishing effects as it proceeds over the land. The breeze commonly penetates inland about ten miles, but naturally to a greater extent when acting with the prevailing southwesterly winds of the coast, while it may be wholly overcome if opposing them. Thus the south shore of Long Island is favorably situated to receive the full benefit of the sea breeze. The sandy plains of southern Long Island rise gradually toward a ridge of low hills extending through the centre of the island nearly from the western to the eastern extremity, and which bear a considerable growth of timber. The northern side of the island is, therefore, somewhat sheltered from the force of strong sea-winds, which meet with but little obstruction on the southern shore."

Long Island, together with the rest of New York State, is influenced by the prevailing northwesterly winds of the winter; but these, not being constant, produce an alternation of maritime and continental climates—the continental type prevails during the summer. On Long Island the continental type is less marked in winter than in any other portion of New York State.

The following table affords an opportunity to compare many widely separated localities:

Table I.—Temperatures (Mean).

	January	July.	Extremes.		Range.
			High.	Low.	
Block Island	31.0	67.6	83.0	54.0	31.0
Nantucket	33	67.3	80	54	26
Long Beach [1]	....	70	88	63	25
Cutchogue [1]	30.4	71.3	94	53	46
Setauket [1]	30.5	71.8	95	54	41
New York City	31	74.1	99	57	42
Atlantic City	32	73	94	58	36
Philadelphia	33	78.2	100	57	42
Baltimore	34	78.7	104	57	47
Denver	27	72.4	96	49	47
Los Angeles	53	70.4	91	56	35
San Diego, Cal	56.8	66.7	77	60	17

[1] All points except Long Island (Govt. 1898). Or Long Island, 1900, with allowance for excess over normal + 2.3 for Long Beach and Setauket during July.

Taking Block Island observations as representing the eastern end of Long Island, and Long Beach the south shore, it will be seen that these localities have the coolest climate in midsummer on the Atlantic coast between Florida and Maine, with the single exception of Nantucket.

The effect of the ocean on range of temperature is marked on the south shore, it being but 25° for July, and with Nantucket standing next to and a close second to San Diego, Cal. (17°).

But four places in the United States have so low a range, viz.: Corpus Christi (22°); Eureka, Cal. (16°); Galveston, Tex. (19°); and Key West, Fla. (18°); but these places are undesirable for residence during July, all having a mean temperature of over 81.6°, except Eureka, which is too cool, being but 54.6°.

The average daily difference in temperature between day and night was 7.3°, taking 3 P.M. (the hottest time of the day) and 8 P.M. for comparison.

The climate of these portions of the island may be summed up as cool, comparatively dry, and very equable. Fogs are rare.

Table II.—Mean Temperatures.

	M.	June.	July.	August	September.	October.
Block Island	51.4	61.6	68.8	68.1	62.7	55.2
Setauket	61.4	67.0	71.8	71	66	51.9
Long Beach	....	67.1	70	70.5	66.3	56

[1] Annual Report of New York State Weather Bureau, 1896.

TABLE III.—FROST.

	First Killing Frost of Autumn.		
	Earliest date.	Latest date.	Average date.
Easthampton	Sept. 28th.	Nov. 27th.	Oct. 20th.
Flatbush	" 13th.	Oct. 26th.	" 4th.
Jamaica	" 2d.	" 28th.	Sept. 29th.

The influence of the sea upon the east and south shores is well illustrated by the foregoing table. The average date of first frost at Easthampton is three weeks later than at Jamaica on the western end of the island, and inland.

Again, there is a full month's difference between the same two localities in the occurrence of latest frost on record.

TABLE IV.—PRECIPITATION.

	Annual.	Spring.	Summer.	Autumn.	Winter.
Block Island	44.79	10.91	9.49	11.62	12.57
Easthampton	37.50	10.02	8.80	10.08	8.40
Setauket	50.80	12.50	12.50	13.80	12.00
New York City	45.14	10.57	12.76	11.06	10.75

The greatest rainfall is in August, and extends over the northern shore to Setauket, but disappears at Easthampton and the east end. Over the greater part of the interior of New York State the precipitation during the summer is the greatest of the year. The reverse is the case with the east and south shores of Long Island. Sea winds from the southeast find no obstruction along the south coast, but passing inland meet the hill ranges along the north shore and give copious rainfall, as noted at Setauket.

TABLE V.—SUNSHINE TABLE, FROM UNITED STATES GOVERNMENT REPORT, 1898–99. ARRANGED IN ORDER OF NUMBER OF CLEAR DAYS.

	Clear.	Partly cloudy.	Cloudy.
San Diego, Cal	291	26	48
Yuma, Ariz	287	53	25
Fresno, Cal	262	52	51
Phœnix, Ariz	259	71	35
Red Bluff, Cal	243	68	54
Oklahoma	233	64	68
Cutchogue, L. I	228	84	53
San Luis Obispo, Cal	226	91	48
Amarillo, Tex	221	86	58
Sacramento, Cal	217	86	62
El Paso, Tex	212	118	35
Narragansett Pier, R. I	208	31	126
Carson City, Nev	202	133	30
Santa Fé, N. M	201	109	55
Bismarck, N. D	198	82	85
North Platte, Neb	193	116	56
Tampa, Fla	178	143	44
Los Angeles, Cal	160	172	33
Denver, Col	150	162	53
Jacksonville, Fla	147	167	51
Setauket, L. I	145	121	99
Atlantic City, N. J	123	139	103
New York City	109	124	132
Nantucket, Mass	91	105	169
Rochester, N. Y	66	136	163

The question of the amount of sunlight is of highest importance in estimating the value of a health resort. It has been found that a want of it will develop symptoms of general depression and a condition analogous to intermittent fever; while an abundance, on the contrary, invigorates, acts as a general tonic, purifies the air, and allows the fullest amount of out-of-door life. The writer is satisfied that this one element of sunlight in the highest degree is a great, if not the most important climatic curative factor in tuberculosis of the lungs, and that which has deservedly given to the climates of Southern California and Arizona their recognized value in the treatment of that disease.

The amount of sunshine on the east end and south shore of Long Island is the most marked characteristic of the climate; Cutchogue, for example, having one hundred more clear days than New York City, and one hundred and sixty-two more than Rochester, in the northwestern part of the State. Again, at Cutchogue, which will represent the eastern end,[1] "during the months of June, July, August, and September, 1899, there were but eleven cloudy days, and during the corresponding months of 1900 there were but seven."

TABLE VI.—SUNSHINE TABLES, UNITED STATES GOVERNMENT REPORT, 1898–99, ARRANGED IN ORDER OF NUMBER OF CLEAR AND PARTLY CLOUDY DAYS.

Yuma, Ariz.	340	Red Bluff, Cal.	311
Carson City, Nev.	335	Santa Fé, N. M.	310
Los Angeles, Cal.	332	North Platte, Neb.	309
Phœnix, Ariz.	330	Sacramento, Cal.	303
El Paso, Tex.	330	Oklahoma, Okla.	297
Tampa, Fla.	321	Bismarck, N. D.	280
San Diego, Cal.	317	Setauket, L. I.	266
San Luis Obispo.	317	Atlantic City, N. J.	262
Amarillo, Tex.	316	New York City.	235
Fresno, Cal.	314	Narragansett Pier.	239
Jacksonville, Fla.	314	Rochester, N. Y.	202
Cutchogue, L. I.	312	Nantucket.	196
Denver, Col.	312		

These tables include all places in the United States where government observations are taken, and are for the year 1898. A few below 200 are used for comparison. The two points on Long Island are for 1899.

TABLE VII.—CLOUDY DAYS.

Nantucket, R. I.	169	Cutchogue, L. I.	53
Rochester, N. Y.	163	Denver, Col.	53
New York City.	132	Fresno, Cal.	51
Narragansett Pier.	126	Jacksonville, Fla.	51
Atlantic City, N. J.	103	San Diego, Cal.	48
Setauket, L. I.	99	San Luis Obispo.	48
Bismarck, N. D.	85	Tampa, Fla.	44
Oklahoma, Okla.	68	Phœnix, Ariz.	35
Sacramento, Cal.	62	El Paso, Tex.	35
Amarillo, Tex.	58	Los Angeles, Cal.	33
North Platte, Neb.	56	Carson City, Nev.	30
Santa Fé, Neb.	55	Yuma, Ariz.	25
Red Bluff, Cal.	54		

Table V. giving the number of clear days at all the government stations in California, Arizona, New Mexico, Colorado, and Texas, where observations are taken, as well as others in Florida and along the Atlantic coast for purposes of comparison, show the portions of Long Island under consideration to have a favorable position in the list among the places having 200 or more days, classing with such as Phœnix, Ariz., El Paso, Tex., and Santa Fé, N. M.; while Denver, Col., Los Angeles. Cal., Jacksonville, Fla., and Setauket, on the north shore of Long Island, are lower in the list, with about 150; Atlantic City having but 123; New York, 109; Nantucket but 91, and Rochester at the bottom with 66.

Viewing it from the standpoint of Table VI., or the number of clear and partly cloudy days taken together, Long Island still holds its place near the points already mentioned in California and Arizona, being equal in number (312) with Denver (the latter place coming up on the list with its large number of partly cloudy days, viz., 162 against Long Island's 84), and still being above Santa Fé, N. M., and other points in California and the Northwest; with Atlantic City and the north shore of Long Island about 265; New York City, 233; Rochester, N.Y., 202; and Nantucket this time at the bottom of the list with 196.

In Table VII., cloudy days, east Long Island still holds its place beside Denver with 53, and classing with San Diego, Cal., and Florida, having fewer than Santa

[1] W. A. Fleet, Government Observer. Letter of December 31, 1900.

Fé and points in California, Texas, and the Northwest; while the north shore has 99; Atlantic City, 103; New York City, 132; and Nantucket again in the most unfavorable position, with 169.

Relative Humidity.—In seeking a healthful climate, its relative humidity is taken into consideration, and particularly when relief is sought for in lung, kidney, and rheumatic troubles.

A residence of several years in pursuit of health in southern California, Arizona, and other dry climates of the West, enabled the writer to recognize, during a vacation last summer on the south shore of Long Island, the marked dryness of the air, and led to the taking of the observations, and later of investigations, the results of which are given in this paper.

TABLE VIII.—RELATIVE HUMIDITY—AVERAGE PER CENT.

1898.	August.	September.
Nantucket	92	86
Block Island	88	82
Atlantic City	87	83
Jacksonville	86	86
Tampa	86	85
San Diego	83	77
Oklahoma	76	70
New York City	78	75
Los Angeles	71	69
Long Beach	60	54
Santa Fé	52	32
El Paso	52	44
Yuma, Ariz.	50	43
Denver	45	39
Phœnix	44	38
Red Bluff, Cal	31	39

In this table the figures are from Government Reports, 1898, except Long Beach; these were taken in 1900 on the north side of a piazza, about 25 feet from the ground, with hygrometer.

For convenience when writing, we might class a climate with

About	55	per cent.	of relative	humidity,	as very dry.
From 60 to 65	"	"	"	"	dry.
" 65 to 75	"	"	"	"	medium.
" 75 to 85	"	"	"	"	moist.
Above 85	"	"	"	"	very moist.

It will be seen by this table that the south shore in August and September may be classed as dry—much drier than any location on the Atlantic coast, or Los Angeles and San Diego on the Pacific.

Summary.—Five elements go to make up a climate—earth, air, water, sunlight, and temperature. The best possible soil to insure good drainage, pure water, and the least amount of moisture to be given off to the air is sand and gravel. This constitutes almost the entire island. The configuration of the land is good, a central ridge with gradually sloping plains to the sea on one side, with boldly indented shores and an inland sea on the other.

The air is both ocean and shore, with great mobility, due to the constant daily ocean winds. The water from the wells and springs is of the purest, freer from salts and vegetable matter than that in ordinary soil or mountain regions. The water of the air has already been referred to under humidity, clouds, fogs, rain, etc., and it is not anywhere in the island excessive; in fact, over the greater portion it compares in amount favorably with some of the most celebrated coast climates.

This study was not commenced with any preconceived ideas or prejudices, but simply, having observed certain symptoms always occurring in dry climates, I was led to go over all the information obtainable, and have given the facts found. They were certainly a surprise, as they probably will be to some of you. I do not pretend to account for the existence of this limited area of excessive sunshine and dryness of atmosphere in the midst of a moist coast-line. Our knowledge at present of upper currents and cloud distribution is limited, and the answer must come, if at all, from students of those subjects.

The practical side of the question is that we have a climate within from one to three hours of New York, where many suffering from diseases that will at once suggest themselves to you may, by a sojourn or residence, be benefited; also, that it is worthy of investigation as to the extent of its therapeutic value. It is certainly worth a trial, when for many reasons a long journey to the Rocky plateau or Pacific coast is inadvisable. Its best field would seem to be in those cases of heart, lung, kidney, and rheumatic troubles in which rapid oxidation is desirable in a sunshiny, dry, slightly stimulating climate, at a low level, and where during from four to six months, or from May to October, almost every day may be with comfort passed out-of-doors, under a sky that for absence of clouds has no rival in the United States outside of Arizona and California, with the exceptions of Amarillo, Tex., and Oklahoma, Okla.

49 WEST FORTY-FOURTH STREET.

SUPERHEATED AIR IN THE THERAPEUTICS OF CHRONIC CATARRHAL OTITIS MEDIA.

BY GEORGE W. HOPKINS, M.D.,

CLEVELAND, OHIO.

FEW ear diseases prove as obstinate in the hands of the physician as does chronic catarrhal otitis media in its advanced stages. The persistency with which many of these cases defy our best measures and steadily progress from bad to worse is familiar to all.

Some four years ago, while employing superheated air extensively in the treatment of various joint diseases, it occurred to the writer that the same agency might prove satisfactory in the treatment of such cases of chronic catarrhal otitis media as are characterized by ankylosis of the ossicles.

Experiments instituted in a number of typical cases at that time revealed the fact that, while there were many obstacles to the successful employment of superheated air in ear work, the results were most brilliant when these obstacles were once overcome.

The treatment has since been employed in a large number of cases of this type with highly satisfactory results, and with improved technique the treatment has been rendered simple, safe, and satisfactory.

A description of the first case treated may be of especial interest, as it has had the best test of time, with no evidence of recurrence four years from the date of discharge.

CASE I.—John L——, aged fifty-three years; a carpenter, with excellent family and personal history, has never been seriously ill, but has had nasal catarrh for fifteen years and gradually increasing deafness for ten years.

Examination revealed a typical case of hypertrophic rhinitis. The watch tick could be faintly heard with the watch in very close contact with the left ear. The tick could be heard at a distance of three inches from the right ear. The left ear was selected for the test.

Diagnosis: Chronic catarrhal otitis media, with sclerosis and displacement of the tympanum, ankylosis of the ossicles, slight dilatation of the Eustachian tube, and some labyrinthine involvement.

The diagnosis was confirmed by two colleagues of reputation as aurists, before treatment was instituted. Regular, systematic treatment, continued for two

years before this experiment was made, had scarcely stayed the progress of the disease.

Treatment: The ear was thoroughly cleansed with alcohol for several days before treatment was instituted. The patient was then seated in a comfortable chair, the ear examined and found perfectly clean. Narrow strips of dry gauze were packed into the ear and a large pad of dry gauze placed over the ear. The ear was then covered with the canvas-sleeve hot-air conductor, and a current of air sent into the canal at a temperature which gradually attained 400° F.

The temperature was easily borne, if gradually increased until a high point was reached, the only discomfort attending the treatment arising from a severe headache which always followed it, but which was promptly relieved by a dose of codeine.

Following the hot-air treatment, the Eustachian tube was always inflated with a warm stimulating vapor

from a nebulizer, vibratory massage with the nebulizer completing the treatment.

The patient was not allowed to leave the office for a half-hour after treatment, and the ear was tightly packed with warm cotton before he went out.

The nose and pharynx received appropriate treatment with antiseptic washes, etc.

Treatments were continued on alternate days for three months, at the end of which time he could hear the watch tick distinctly at thirty-four inches, and surprised his friends by invariably replying to their whispered references to him.

The right ear was then similarly treated, and in ten weeks an equally good result was secured.

Examination showed that the ears were normal in appearance. The patient was discharged January 6, 1897, and careful tests made at frequent intervals since have shown no tendency to recurrence.

During the four years subsequent to this experiment the writer has treated sixty-two characteristic cases of this disease with but four failures, and these occurred in very old people, all of whom had extensive labyrinthine involvement.

It may have been my fortune to find cases which were especially amenable to this treatment, but, in my opinion, any physician who will study technique closely can secure fully as good results. As to the philosophy of this treatment, little can be said at this time.

The intense heat seems to stimulate the circulation through the blood supply on the posterior side of the manubrium, causing absorption of the articular deposits; removing atrophy and relieving the rigidity of the tensor tympani. The ossicles lie so near the surface that they receive the full benefit of heat applied to the tympanum, and adhesions between portions of the ossicular chain and the adjoining bony walls of the middle ear are readily removed.

Naturally, much better results are secured in the same period of time in hypertrophic cases than in those characterized by hyperplasia; but many cases of the latter type, which would ordinarily have been regarded as hopeless, have gradually improved under this treatment until marked benefit was secured.

The writer has always regarded as contraindications to the employment of this treatment: (1) Arteriosclerosis, (2) serous effusion into the tympanum, and (3) perforations of the tympanum.

More recently he has treated several cases in which small perforations existed, without meeting with any difficulty, but ordinarily it would be advisible to exercise unusual care in treating such cases by this method. Aside from the headaches previously mentioned, there have been no troublesome after-effects to require attention. Such accessory forms of treatment as may be indicated should not be neglected.

Apparatus: For generating the necessary superheated air the writer prefers the device illustrated. This apparatus is a simple room-heater operating either by gas or oil, and having a funnel-shaped top, which sends the hot air through the canvas sleeve to the ear under treatment.

A few points in the construction of this device are of importance: (1) There must be sufficient draught to secure perfect combustion, without having an excessive draught, which wastes heat, and (2) there must be at least one perforation in the canvas sleeve near the point of contact with the ear, or the dead-air space present will prevent hot air from reaching the ear.

The gauze packing within and over the ear takes up all moisture as rapidly as formed, preventing burning and making the application of very high temperatures easy and without discomfort.

Although it is difficult to introduce currents of hot air to a cavity like the ear, which is open at only one end, if the above-mentioned precautions are observed no difficulty will be experienced.

The writer has experimented with a number of more elaborate heating-appliances in these cases, but none has given better results than the simple one above described.

1016 New England Building.

Bony Junction of the Hyoid and Thyroid.—P. Sebileau reports a curious formation occurring in a patient coming under his observation. It consisted in a bony prolongation from the middle of the body of the hyoid bone on its anterior surface downward to about the middle of the anterior surface of the thyroid cartilage. This condition is one of normal occurrence in certain of the lower organisms (especially the reptilia), and shows in the opinion of the author that the thyroid cartilage is of branchial origin and that it does not properly belong, from a developmental point of view, to the cartilaginous skeleton of the larynx.—*Annales des Maladies de l'Oreille, du Larynx, du Nez et du Pharynx*, April, 1901.

THREE CÆSAREAN SECTIONS—RECOVERY.

By J. F. BALDWIN, A.M., M.D.,
COLUMBUS, OHIO,
SURGEON TO GRANT HOSPITAL; FELLOW OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNÆCOLOGISTS, ETC.

Case I.—Mrs. W——, aged twenty-four years, weight one hundred pounds, height forty-seven and one-half inches, was seen with her physician, Dr. Heeter, July 12, 1889. She was a typical rachitic dwarf at about full term of gestation. Examination showed a uniformly contracted pelvis with a conjugate diameter estimated at one and one-fourth inches. Her hygienic surroundings were bad, as she lived with her husband in a cellar basement. Nevertheless arrangements were made for a Cæsarean section as soon as labor commenced. July 16th, 10 P.M., I saw her again. Labor had commenced, the pains were short and frequent, and the os just beginning to dilate. She had felt the pains for about five hours. Morphine was given, hoping to delay labor until daylight. The pains, however, increased, and at 2 A.M. on the 17th it was evident that longer delay was inadvisable. At this time the pains recurred every three minutes and the os had dilated to the size of a twenty-five-cent piece. Assistants were at once secured and the operation was performed. Chloroform was administered by Dr. W. H. H. Nash. Dr. E. J. Wilson assisted directly, while Drs. Leeper and Kistler performed the special duties prescribed for them. The operation was done after Tait's method. The abdomen was opened in the usual way, a rubber tube thrown around the cervix and drawn tight, a longitudinal incision made in the uterus, this incision being torn by the fingers to a sufficient extent, a leg was grasped and the child promptly delivered. The placenta was at once extracted, the womb lifted out of the abdomen, the rubber band still further tightened, the cervix transfixed by knitting needles, and the womb, together with the ovaries and tubes, cut off. There was no hemorrhage. The incision was closed in the usual way down to the stump, which was treated with perchloride of iron. Convalescence was prompt in every way, and the patient was dismissed in three weeks. The child weighed seven and one-half pounds, and was nursed by the mother as if delivery had occurred in the usual way.

According to the statistics of Dr. R. P. Harris, of Philadelphia, this operation was the ninth among American Porro operations, and was the third successful one. It was the first Porro operation in Ohio.

Case II.—Mrs. McC—— aged twenty-nine years, was seen with her physician, Dr. E. J. Wilson, May 8, 1900. She was pregnant at full term and had been in labor for about ten hours. Her physician had been called about four hours before and found her in hard labor, the membranes ruptured, and the os thoroughly dilated. She had been delivered by another physician, two and a half years previously, by craniotomy. This operation had been found difficult, as so reported by her physician, and she had been left with a vesico-vaginal fistula. Knowing the previous trouble, her physician on this occasion waited two hours, hoping that the head would engage. This failing, he applied the forceps, but was unable to secure any engagement. After waiting two hours more and finding no advance he asked for consultation, with the view of a Cæsarean section. On making a personal examination I found the conditions as above indicated. The presentation was by the vertex, L. O. A. The woman's condition was still good, although she was suffering greatly from her pains. The fœtal heart could be distinctly heard. Under the circumstances, therefore, and in view of her previous labor, a Cæsarean section seemed clearly indicated. The patient assenting, she was at once transferred to the Washington Avenue Hospital and the operation commenced at 11:30 A.M. Chloroform was administered by Dr. C. M. Shepard, Dr. E. J. Wilson assisting directly, and Drs. S. B. Taylor, Chapman, Fisher, and Willey, and H. A. Baldwin being present to aid as needed. The abdomen was opened in the usual way sufficiently to permit the withdrawal of the uterus, back of which towels were placed to protect the intestines. The organ was then incised transversely across the fundus. Hemorrhage had been guarded against, although perhaps unnecessarily, by my assistant grasping the broad ligaments on each side so as to control the flow of blood through both the uterine and ovarian arteries. The placenta was attached to the left side and was not in the line of incision. A presenting knee was at once seized and the child extracted without difficulty. The placenta was then easily delivered and the incision closed with chromicized catgut in two layers, numerous superficial sutures being used so as to leave no raw surface exposed. The Fallopian tubes were removed into the horn on each side, so as to prevent future pregnancies. The ovaries were entirely healthy and were left. The incision was closed in the usual way. The child, which was a large-sized male, was not asphyxiated at all, but in a moment cried lustily. Mother and child left the hospital in about two weeks.

Case III.—Mrs. W——, aged thirty-two years, was first seen August 18, 1900. She was married two years, and had menstruated regularly, the last time being December 26, 1899. Motion was first detected May 7th. She presented marked deformity of the pelvis with congenital dislocation of both femurs. August 26th she was carefully examined by Dr. E. J. Wilson and myself. Our measurements, which agreed exactly although made independently, gave the diameter between the iliac crests 24 cm.; between the iliac spines, measured by Harris' method, 21 cm.; external conjugate, 15.5 cm. The patient's abdomen gave every evidence that she was about eight months pregnant. The case was clearly one for Cæsarean section, and this operation was advised and consented to. September 17, 1900, the patient notified me that she was in labor, and on visiting her at her residence I found this to be the case, and accordingly took her in my carriage to Grant Hospital, where the operation was performed as soon as the patient could be gotten into condition, at 3 P.M. Chloroform was given by Dr. C. M. Shepard, and Dr. L. J. Chapman acted as my assistant. A number of physicians of the city who had known of the case were present by invitation, together with several of the hospital nurses. The operation was conducted precisely as in Case II., the transverse incision through the uterus in this case, as in that, giving remarkably little hemorrhage. The incision came directly down upon the placenta, but this was immediately separated so that there was no special loss of blood. The child presented by the buttocks and was easily extracted. It was slightly asphyxiated, but was resuscitated with no special difficulty. In this case, as in the second, the Fallopian tubes were removed so as to avoid future pregnancies. The anæsthetic was not well borne, so that the operation was somewhat prolonged owing to the struggles of the patient, but was completed without any special delay. The child was a male of average size and thrived from the first. The mother left the hospital in excellent condition in three weeks.

The indications for a Cæsarean section in these three cases seem to have been very clear, and the results, both in the entire absence of mortality, either maternal or fœtal, and in the absence of morbidity, all that could have been desired. The technique of the Porro operation was in accordance with the teaching of that time. Were I to have a similar case to-day which for any reason it seemed best to complete by Porro's meth-

od, the uterus would undoubtedly be removed, as in any other case of abdominal hysterectomy, with dropping of the stump and immediate closure of the abdomen. Unless, however, there was some special reason for removing the uterus, such as the presence of tumors or sepsis, it would probably be best to close the uterine incision, as was done in the other two cases, and allow the organ and the ovaries to remain. While the physician should not render a woman sterile without her knowledge and assent, and that of her husband, I personally do not feel that it is right to subject a woman a second time to a Cæsarean section without her own expressed desire. In both the cases the matter was fully presented to the patients, and both promptly expressed a desire to be left in such condition that subsequent pregnancies could not occur.

Columbus has been unfortunate, apparently, in the mortality of its Cæsarean sections. From careful inquiry I have learned that during the last twenty-five years there have been, including the above cases, nine Cæsarean sections made in Columbus, these operations having been made by four different surgeons. In six of these cases the mothers all died promptly. The fœtal mortality has not been learned. The total maternal mortality therefore has been sixty-six and two-thirds per cent.

ETHER AS AN ANÆSTHETIC.[1]

By EDWARD JUDSON WYNKOOP, M.D.,

SYRACUSE, N. Y.,

ATTENDING SURGEON, SYRACUSE FREE DISPENSARY; ATTENDING PHYSICIAN AND SURGEON TO THE CHILDREN'S WARDS, WOMEN'S AND CHILDREN'S HOSPITAL; LECTURER ON ANATOMY, COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY.

Mr. President and Fellows: In presenting these lines for your discussion this evening, it is not my intention to bring before you the many ways in which ether can be administered or its physiological action, but to formulate a few suggestions which may be of value.

The one idea in every operative case in which narcosis is needed, is to choose some form of anæsthetic which will render the patient unconscious, and, at the same time, with the least possible amount of danger.

Many will say, "Why do you bother us by bringing this oft-told subject up for discussion?" How often is ether given, and how few are the deaths! How few? Yes, and could not these few have been spared had a more careful physical examination been made, more care used in the administration of the anæsthetic, or a more expert anæsthetist been present? This is the object in bringing this paper before you to-night.

Can we not, by more careful attention to all these details, render disaster an almost unheard-of occurrence? In ether, properly given, with but few exceptions, we have a safe and reliable anæsthetic. Even in the case of children, with whom chloroform was formerly invariably used, ether is fast taking its place. In pregnancy, kidney disease, and the varoius pulmonary troubles, it is generally contraindicated, but in many of the operations around the face and throat, ether is fast coming into favor. Its physiological action is too well known to detain us, but its safety lies in its being a respiratory and cardiac stimulant.

Many of the objections put forward by the antagonists of ether can be summed up as follows: First, it takes a longer time to get the patient anæsthetized. Second, it irritates the throat, fauces, and lungs. Third, it causes a sensation of strangulation. Fourth, it congests the kidneys, causing some form of kidney disease. Fifth, it causes vomiting, and frequently nauseates long after the operation has been finished.

Granted that ether may take a few moments longer in its effect than chloroform, in competent hands its action is prompt and sure. When these many objections are brought to your notice, before you condemn the ether, ask a few questions. Was that ether fresh, and, if so, was it given properly and by a competent person? Was the cone a proper one, and made to fit the patient's face? Was the ether frequently added, and in small quantities, or was a cone saturated with stale ether slapped down over the face of the already scared and nervous patient, and allowed to remain there to fill with foul secretions before fresh ether was added? If so, is it a wonder a patient struggles and complains of strangling, irritation of the throat, and vomiting? When a patient vomits and is nauseated for hours after ether, can any one wonder, since a filthy cone, seldom changed, has been held over the face for a long time? If pulmonary trouble follows, instead of condemning ether, we should look to its method of administration; see how much more ether was given than was necessary; see if frequently during the narcosis the patient was not allowed to vomit, thereby allowing some of the vomited matter to get into the air passages; or see if, possibly, some physical sign indicating a pulmonary trouble has not been overlooked in the hurried physical examination. The same holds true of the kidneys or any of the other organs; therefore, before condemning ether, we should look to its administration.

Just for a moment let me remind you of a few of the points in its administration. Time does not permit me to dwell at length upon the urinary or physical examination, but this should be thorough. No food should be given six to ten hours before the administration of an anæsthetic, especially ether. The giving of a glass of milk three or four hours before the commencement of anæsthesia is a practice to be condemned, and it needs but one experience with vomited milk curds to make one see its danger. Ether should never be given without a hypodermic of strychnine and stimulants ready for instant use. Oxygen and an electric battery should also, if possible, be at hand; the head low, chest and abdomen free, false teeth and plates removed, are a few of the well-known points. A cone of towel and paper forms a clean and convenient inhaler. Fresh ether, frequently added but in drachm doses, should be used, and we should begin the inhalations with the cone at some distance from the face, allowing the throat and fauces to become accustomed to its vapor before bringing it down closely over the face. The mouth gag and tongue forceps are at times convenient, but seldom necessary. With the jaw held forward, and a little care taken in a patient's position, these instruments will enjoy a much-needed rest in the pocket of the skilled anæsthetist. The anæsthetist should give the ether and nothing else. His undivided attention should be given to the patient, watching for any and every sign of danger. To him belongs the entire responsibility of bringing that patient successfully through the narcosis. No one sign should be overlooked. Everything should be carefully watched; pulse, respiration, pupils, face, everything, nothing should escape the vigilant eye of the etherizer. Many times you have seen incompetence at the cone; the anæsthetist first giving too much ether until the patient is profoundly anæsthetized, then letting up until the patient vomits, and, if it happens to occur in an abdominal section, the protruding gut not only annoys the operators, but considerable shock follows the replacing and handling of the intestines and the prolonging of the anæsthesia. In operations around the throat and face, what is more annoying than a vomiting or gagging patient? The question has often come to my mind, whether a great deal of the trouble experienced by operators in the healing of the abdominal wounds was not the result of too much manipulation of the cut surfaces, caused by the

[1] Read before the Syracuse Academy of Medicine, October 23, 1900.

replacing of protruding intestines, or working with rigid abdominal walls, or by the persistent vomiting and retching after a prolonged narcosis.

I well remember a rule which the late Prof. Charles Carroll Lee, of New York, used to insist upon. It had been the duty of the youngest man on the staff to give the anæsthetic, but Dr. Lee always insisted that the post of the anæsthetist should be filled by the most competent man on the staff, and invariably the house surgeon took the ether cone instead of acting as first assistant, thereby insuring a safe narcosis for his patients.

Dr. A. M. Phelps, of New York, some time ago pointed out the fact that by rapid operating and keeping the patient under ether the shortest possible time, shock was greatly lessened; and his results have been surprisingly good.

It would seem to me that the time is ripe for the profession of this city to support a man who makes it his business to give anæsthetics and to administer them properly. In large cities of this country and in Europe this is done, and it is time we did it here.

I never witness an operation, especially if it is a major one, without wondering if the anæsthetist is competent to carry that case through a prolonged narcosis, and if he fully realizes his responsibility. What will be his compensation? Who is it that for many a weary moment watches every sign and symptom of impending danger, keeping the patient safely and quietly anæsthetized, enabling the operator to work unhindered by tense and rigid muscles, by vomiting, retching, and the various unfortunate occurrences; and, when the operation is finished, the patient is carried to bed, not to remain in a profound stupor for hours, but soon to show signs of returning consciousness. Who is it that is responsible for that patient's life during the narcosis? You know only too well, should death interrupt the proceedings. Do you believe it fair for the operator to receive a good fee for his work, while the man who is responsible for the welfare of that patient receives sometimes a "V," seldom a three, and generally nothing? I think it is a disgrace to the medical profession—the treatment and pay of the average anæsthetist. I do not refer to charity patients or when the operator works for but little, for any one is willing to help his fellow-practitioners, but in good cases the average anæsthetist receives mighty scant remuneration.

Ask any physician who is about to undergo an operation whom he wants to have to give him an anæsthetic. Will he ask a nurse, a medical student, or an unskilled physician to officiate? No, not by a good deal; and we owe our patients the same consideration. It is a fact well known that a mighty small percentage of medical men, and surgeons at that, can properly administer ether, to say nothing of chloroform. The failure of our medical schools to give this subject its proper place is a great mistake. A student should be instructed day after day at the operating-table, watching the different symptoms as the narcosis continues, familiarizing himself with every detail, so when at last a patient's life is trusted to his care the operator can operate, and the assistant and nurses attend to their proper duties. Why? Because the anæsthetist knows his business, and the operator is free to work as only one can with whole heart and mind at his task. I firmly believe it is absolutely wrong for any one to allow an inexperienced person to give an anæsthetic when an experienced one can be obtained. In emergency cases this cannot always be done, but we can attempt it. I fully believe a competent anæsthetist will carry many a desperate case successfully through the dangerous stages of an operation, and, when it is completed, the patient will have more vitality left with which to make a new start in life.

There is one little point which has often come to my notice, and it might be well to mention it here. A great many men before operating, if they are to use chloroform as an anæsthetic, will try to secure some one who has had some experience in its administration. For that reason, deaths from chloroform are not so numerous as they would be if the operators took the same chances they do with ether. Taking into consideration how much ether is given every day, and often by incompetent persons, the death rate is remarkably small, which speaks volumes for its safety as an anæsthetic.

A few years ago, after some rather unpleasant experiences with chloroform, the following notice was posted in the operating-room of a New York hospital: "Chloroform as an anæsthetic is not to be used in this hospital, except in obstetrical cases and children, without calling in consultation another member of the attending staff of this institution." In alcoholics, who as a class are undesirable for any anæsthetic, ether, if properly given, will be found to be satisfactory. The preliminary use of hypodermics of atropine and morphine is good in certain cases, but, when possible, they should not be used. The practice of beginning narcosis with chloroform and then changing to ether should be condemned. Those who live in the country will say, "How can we obtain a skilled anæsthetist?" Possibly you cannot, but if more care and attention are given to a few important details, the results of an ether narcosis will be much better.

To sum up briefly: First, ether from its physiological action is the safest of anæsthetics. Second, more care is necessary in preliminary examinations, and more care in regard to the position and condition of patients during the narcosis. Third, a good inhaler—the simpler the better is needed—with fresh ether, made by a reliable firm, and for this purpose the small quarter-pound cans are the best; the ether is to be added in small quantities frequently, beginning the narcosis with the inhaler a short distance from the patient's face and gradually bringing it down. Fourth, the more detailed study of this important subject is called for in our schools and hospitals. Fifth, the presence of a trained anæsthetist at all operations is necessary.

A FEW OBSERVATIONS FROM THE LORENZ ORTHOPEDIC CLINIC.[1]

By LEONARD W. ELY, M.D.,

NEW YORK.

It was the writer's good fortune to be in Vienna for a while this last summer, and he improved the opportunity to see Lorenz. Lorenz gives a regular course in the general hospital, at which a number of Americans are usually present, and besides this, if one be lucky enough to have an introduction to him, one is invited to a private hospital where he does much of his work.

In the public hospital he has no wards of his own, but treats his patients there in his ambulatorium, his out-patient department, occasionally, it would seem, sending them up into what were, at the time, Albert's wards. His quarters are small and are usually crowded with assistants and spectators. His first assistant gives the anæsthetic; a practice more common on the other side than on this, and worthy to be copied.

It seems strange to see many of our well-established ideas set aside and ridiculed, and appliances adopted which we would consider clumsy and unscientific. Where we use plaster, Lorenz often uses a brace, and for our brace he substitutes plaster. In spinal caries

[1] Read before the orthopedic section of the New York Academy of Medicine, December 21, 1900.

we discuss the merits of the Taylor brace and the plaster jacket; some use one, some the other, and some use both. Lorenz discards both and advocates the use of a corset. This corset is made of two broad strips of perforated celluloid strengthened by metal bands, running down the back and over the hips and moulded to fit over a plaster cast. These are continuous with some stout stuff like canvas, the halves of which, meeting in front, are laced like an ordinary corset. Lorenz is wont to descant on the merits of this appliance, and probably in an ordinary case it is a fairly efficient brace; very much like many of our corsets, keeping the spine more or less rigid, and so rendering the patient comfortable; but that it prevents deformity and "splints the spine" hardly seems likely. It seems clumsy. His patients, as a rule, are poor, and the hospital supplies no free braces, but the supply of plaster is apparently unlimited. Unfortunately a stay of a month or so does not afford a chance to measure increase of deformity or occurrence of complications, and the careful tracings by which we set such store are conspicuous by their absence.

In the treatment of diseases of other joints, plaster is the favorite material. In hip-joint disease, Lorenz discards braces and puts the limb up in a plaster spica, which usually has an iron strip running down from the bottom to take up the weight of the body. In certain cases the method would appear to be a good one, especially in adults, and in children in the stage of recovery. In the former all brace treatment is difficult, and in the latter it is not very efficient in preventing deformity. Theoretically a spica should be a good weapon with which to combat troublesome persistent flexion and adduction.

Of the machine for the forcible correction of deformities you have all heard. It is a most impressive instrument and serves many purposes, but, except in the matter of time-saving, it seems to have little advantage of the hand. It can, of course, do considerable harm if not properly used.

His lateral curvature cases Lorenz treats in classes, and probably gets the same brilliant results as the rest of us do. The writer did not get a chance to see the children under treatment.

And now for the work with which Lorenz's name is so closely connected, and which we go to see him do —his congenital dislocations. His material is great, so that in a month with him one sees as many cases as in an ordinary clinic in a year. Patients are sent there from all over Europe. The Sultan of Turkey, the writer believes, has a child on which he wants Lorenz to operate in Constantinople. Even young sultanesses have the same diseases as the rest of us. The man is an enthusiast on his operation, and his results seem remarkable. His statistics are more favorable than any one's else. We may assign this to his method and technique or to his enthusiasm. Probably both causes contribute. His new book gives a detailed account of his operations, and tells how he does them. In actual practice he does not appear to cut tendons with as much freedom as in his book he advocates, nor, as a rule, did he use instrumental traction. It did not fall to the writer's lot to see him do an open operation. All the work done was without the use of the knife.

Besides those patients operated on during the writer's stay there were quite a number in the various other stages of treatment. Lorenz puts on the first spica, and then tells the patient to go away and stay for several months. He evidently has great confidence in the staying powers of his spicas, and this is remarkable when one considers how narrow is the bridge across the pubes—about two inches. They are certainly things of beauty, carefully moulded on the pelvis, do not include the trunk, and run only to the knee.

The results of the bloodless operation are good, at times brilliant, and leave no doubt, in the minds of those who have seen them, of the wisdom of operating. If not operated on, nothing is left for the patient but the life of a hopeless cripple. If operated at an early age, almost always great improvement results, often a good joint, and sometimes an almost perfect one. It is worth trying in a single case up to ten years, and in a double case up to seven, and even if this operation fails there is still hope with the knife.

Lorenz looks forward to the time when, owing to the spread of knowledge, these little patients will be brought earlier for operation, and the age problem will not confront us. Failures then would be few. Says he: "Das interessirte Publicum nimmt sehr lebhaften Antheil an den Fortschritten der Luxationstherapie, und ist, nach meinen Erfahrungen darüber, in der Regel weit besser unterrichtet als im Allgemeinen selbst die Aerzte."

Now, of course, Lorenz is one of the most modest of men, for he says, again speaking of his earlier operation, that it seems impossible to imagine how any better operation could possibly be devised for this deformity, and then proceeds to tell how it has been surpassed (überholt) by his later one (p. 159).

In conclusion it might be remarked that one is strongly impressed by the willingness with which Lorenz demonstrates his methods. He has the air of one convinced of the merits of what he is doing, and gave us all the chance to get our hands on the patients, and see for ourselves what was done.

170 West Fifty-eighth Street.

A CASE OF MEMBRANOUS ANGINA, DUE TO STREPTOCOCCI, FOLLOWED BY PARALYSIS OF THE SOFT PALATE.

By MOSES KESCHNER, M.D.,
NEW YORK.

M. B——, aged twenty years, was admitted on April 3, 1900, to the Reception Hospital. Previous family and personal history was good. She had been ill one day before admission. On admission the lungs, heart, and abdomen were found negative. Throat: The tonsils, uvula, anterior and posterior pillars of the fauces were covered with a thick, dirty, yellowish-gray, tenacious membrane. A smear from the same showed short-chained streptococci, a few staphylococci; no Klebs-Loeffler bacilli; a culture on blood serum examined after twelve hours' incubation showed almost a pure growth of streptococci. By April 7th the membrane began to break up, and had entirely disappeared by the 10th. During all this time the patient presented the classical symptoms and signs of local diphtheria, and gave evidence of profound systemic infection, a marked feature of which was maniacal delirium, lasting for seventy-two hours, which could be controlled only by large doses of hyoscine hydrobromate. On the 11th, it was noticed that the patient had difficulty in swallowing; the voice began to acquire a nasal twang, and on the next day liquids regurgitated through the nose on deglutition. On inspection, the palate was seen to hang more vertically than normal, and when she was asked to say "Ah," the palate was not raised. There was also a distinct loss of sensibility in the palate. There was no loss of the knee jerks; the pupils reacted to light normally; vision was not impaired. There was no evidence of paralysis in any other part of the body. Large doses of strychnine were administered by the mouth, and on April 20th the patient was discharged with only beginning improvement of the paralysis.

In the article on diagnosis in diphtheria in almost all text-books, one finds the statement that "paralysis following a pseudo-membranous angina is proof positive that the angina was caused by the presence of Klebs-Loeffler bacilli, but that the bacilli were so few in number that they may have been overlooked in the examination, or that they may have been overgrown by the cocci." As far as overlooking of the bacilli is concerned, I would say that this can be ruled out on the grounds that the bacteriological technique in the case was almost perfect, the cultures and smears having been carefully examined by two members of the hospital staff, and the results confirmed by the bacteriologists in the laboratory of the health department of the city of New York. This would rule out "personal error." The question of overgrowth is overruled by the fact that the successive serum cultures examined were in the thermostat for ten, twelve, and eighteen hours, and besides smears directly from the membrane were examined daily and found to contain only streptococci, with a few staphylococci and diplococci.

A third objection might be the possibility of the Klebs-Loeffler bacilli having disappeared from the throat prior to its examinination in the hospital. This, although possible, is not very probable, inasmuch as the case was seen on the first day of illness by the health department inspector, who took a culture (as is the rule with all cases before admission), and it was returned negative as to the presence of Klebs-Loeffler bacilli, and, although anatomically a "straight" case of diphtheria, was admitted to the Reception Hospital as a "suspect."

The above points would seem sufficient to exclude the Klebs-Loeffler bacilli as the etiological factor in the production of the paralysis in the case, and I should ascribe the paralysis to one of two things, or possibly both: (1) Pressure paralysis from direct action of the inflammatory process. The palatine nerves being contiguous to the inflammatory process of the primary disease, it is probable that they are influenced by the abundant growth of micro-organisms in the false membrane, which often penetrate into the substance of the mucous membrane, and even to the tissue beneath. (2) A neuritis with paralysis, due to the action of a toxin generated by the streptococci, in the same manner as we get a neuritis from the toxins generated by Pfeiffer's or Eberth's bacillus. Indeed, some experimental work has been done by Widal and Bézançon (*Annales de l'Institut Pasteur*, tom. ix., part ii., p. 104), in the course of which the authors succeeded in causing paralysis in seven rabbits out of one hundred and sixteen by inoculating them with toxins of various streptococci.

Baginsky (*Archiv für Kinderkrankheiten*, Band xiii., p. 455) reports a case of diphtheria with fatal paralysis of the diaphragm. No Klebs-Loeffler bacilli were found. He says that possibly they had disappeared, but he believes not.

Bourges (reviewed in *Rev. Mens. des Mal. de l'Enfance*, tom. xiii., No. vi.) reports: A seven-year-old boy had a pseudo-membranous angina, lasting seventeen days. Bacteriological examination demonstrated the absence of diphtheria bacilli and streptococci. The mother was infected, and her throat was also negative as regards the diphtheria and streptococci. Fifteen days after the disappearance of the pseudo-membrane, the child developed a convergent strabismus, followed in a few days by paralysis of the soft palate, and then by an incomplete paraplegia, lasting one month. The development of these symptoms accords perfectly with that of diphtheritic paralysis, in spite of the positive absence of specific bacilli.

I do not review this case because it is similar to the one that I report, for in Bourges' case there were not even streptococci present, but to show that paralysis after a pseudo-membranous angina is not positive evidence of the presence of Klebs-Loeffler bacilli.

These are the only cases that I could find in the available literature.

In conclusion, I wish to thank Dr. E. G. Bryant, resident physician of the Willard Parker Hospital, for permitting me to report the case.

352 East Fourth Street.

Practical Hints.—C. Lederer says that if foam remains on the urine for an hour or two one should suspect albumin, while a thin iridescent scum forming on the surface over-night points toward the presence of sugar. Martins has observed that non-coalescence of the cartilages of the ninth and tenth ribs is a sign of weak kidneys and the probability of subsequent Bright's disease. Finely powdered and well-baked clay is a simple, cheap, and efficacious dusting-powder for exuberant granulations about the sinuses of abscesses. Umbilical hernias in infants may almost invariably be cured by the following procedure: A bottle-cork one inch in diameter and one and one-quarter inches in thickness is tapered off at one end, covered with adhesive plaster, and then placed in the centre of a Maltese cross of the same material. The smaller end is pressed into the hernial ring and the apparatus held in place by the cross of plaster. In two weeks the size of the opening will have decreased so that a smaller cork will have to be fitted, and in six weeks the cure is usually complete. Beginning ventral hernia in adults may be treated in the same way.—*Der Frauenarzt*, April 19, 1901.

The Prevention of Puerperal Eclampsia.—L. F. Bennett believes that much can be done in the way of prevention by overcoming intestinal putrefaction by the use of strychnine with salines, by exercise, careful attention to the skin, exertion by the lungs, and ventilation. The urine should be carefully tested not only for albumin and specific gravity, but to know the amount secreted in twenty-four hours. The pulse is a good index to kidney elimination. An increase in arterial pressure is suggestive. Vasomotor constriction should put us on our guard as to the retention of toxic material. The alimentary canal will bear careful scrutiny. Many and various poisons are absorbed from this canal which are a sore trial for the kidneys and are almost entirely unnecessary in the maintenance of life. A saline draught, as some of the aperient waters, should be given, or a teaspoonful or more of Rochelle salts in a half-glass of hot water every morning. The liver should be looked after carefully, and if enlarged or congested will tell us that it is being overwhelmed with toxic material, and the appropriate treatment will at once suggest itself.—*Obstetrics*, April, 1901.

Disinfection from a Purely Practical Point of View; its Efficiency a Problem for Solution.—Results of a series of experiments detailed in J. J. Archinard's paper lead him to the following conclusions: I. Sulphur dioxide, being a disinfectant of low efficiency and, worse still, a destroyer of dyes, while utterly impracticable for thorough application, should be discarded at once. II. Formaldehyde, on the contrary, is an agent of a great penetration and high disinfectant efficiency, though practically harmless to colors and fabrics. Apparatuses are now being made for disinfecting rooms and contents by means of simple, cheap, harmless, and easily managed methods of rapidly generating this gas. Therefore the immediate adoption of formaldehyde is much to be desired. III. Bichloride of mercury recommends itself as a handy and efficient means of treating washable fabrics. IV. Sprink-

ling with twenty-per-cent. solution of formalin and keeping in closed containers for twenty-four hours enables us to dispose of woollen and other wearing-apparel not amenable to treatment by method III. V. Chlorinated lime is our best method for disinfection of excreta, privy vaults, yards, drains, etc. VI. Incineration is the best method of disposing of substances of no intrinsic value, such as rags containing dejecta, etc.—*New Orleans Medical and Surgical Journal*, May, 1901.

The Effect of Alcohol on Animal Life.—The New York *Herald*, Sunday, April 7th, says: "The result of recent experiments on a large scale on animals, made by M. Lainier, a French doctor, to test the effect of alcoholism on the system, will rejoice the hearts of the opponents of strong drinks. He has proved that animals alcoholized are utterly unable to resist infection with the bacilli of tuberculosis or anthrax, and still less with the poison of diphtheria. Moreover, the progeny of alcoholized guinea-pigs are either born dead or are so weak that they survive but a very short time. These experiments will again direct attention to the subject of alcoholism in connection with the decrease of population in France."

Medical Education of Women in Russia.—In 1861 the first formal request was made by a Russian woman for admission to follow the medical course at a university. Contrary to what took place in England, the proposal encountered practically no opposition, either from the profession or the public, and by the following year the sight of women attending lectures in the St. Petersburg Academy of Medicine and Surgery had ceased to be a novelty to any one. Since then the privilege has for various reasons been temporarily withdrawn once or twice, but the medical education of women in Russia is now so firmly established that one of the largest hospitals in St. Petersburg, containing more than six hundred beds, has just been opened for the instruction of the students. At the beginning of 1900 there were five hundred students attending the Women's Institute of Medicine, a large proportion of whom look with confidence to find an outlet for their energies in the Asiatic provinces of the empire. In 1899 a residential college was completed, at a cost of nearly $150,000, to accommodate one hundred and seventeen students.—Alder Anderson in *Strand Magazine* for April.

Chicago Drainage Canal Complications.—In response to the request of the shipping interests of Chicago, says *The Scientific American*, the Secretary of War has given an order that the flow in the Chicago drainage canal must be reduced to 200,000 cubic feet per minute, which is about one-third less than the discharge for which the canal was designed. When the construction of the canal was authorized by the legislature, it was distinctly laid down that, when the sewage of Chicago was turned into the canal, it should be diluted at the rate of 20,000 cubic feet per minute for each 100,000 population, and that the total flow must not fall below 300,000 cubic feet per minute. These stipulations were made in agreement with the laws and in response to the urgent representations of the residents of the valleys through which the sewage-laden waters of the canal would be carried into the sea, and it would simply seem as though the provision for a flow of 300,000 cubic feet per minute is none too ample in view of the unsavory burden that the canal waters carry. Unfortunately, the discharge of this volume of water produces a current which, it is claimed by the shipowners, is dangerous to navigation in the Chicago River. Moreover, the authorities of the city of Chicago are disposed to make much trouble over the question of canal bridges. Thus this magnificent enterprise would seem to be just now placed "between the devil and the deep sea." It is not likely that any of these opposing interests would seriously deny that the drainage canal is a necessity, and that its completion and execution are one of the greatest sanitary works of this or any other age. That a large city like Chicago should continue to pour its refuse into Lake Michigan, with the prospect of ultimately bringing it into the absolutely disgusting condition which obtains to-day in Havana harbor, is a proposition that neither the inhabitants of the Illinois and Desplaines valleys, nor even the city of St. Louis, would justify for a moment. Since the canal is there, and there to stay, it is surely possible in such a reasonable age as this for the contending interests to meet and consider the matter in a practical and broad-minded spirit, and to make a compromise which shall do justice to every interest affected.

Pathology of Pharyngo-Mycosis.—From a microscopical study of tonsillar tissue containing mycosis deposits D. Braden Kyle is inclined to believe that the action of the leptothrix in their production is secondary, and that it is more than likely that the chemical change brought about by the pathological alteration in the submucosa causes a change in the glandular secretion and forms a soil which is a suitable nidus for the proliferation of certain bacteria. The degenerative changes in tissue (as in the tonsils) seem to be largely hyaline. The process of degeneration is controlled by nutrition, and why we have hyaline degeneration in one condition and fatty in another can be explained only from the standpoint of chemical pathology. That the tissues and fluids under certain chemical conditions bring about definite pathological changes is governed by the same general laws that control chemical reaction. Bacteria of the throat, found present in diseased conditions, may be only associated etiological factors. In mycosis, in which so many bacteria are found present, their import is lessened. The life and growth of the bacteria are largely determined by the character of the secretion. It may be possible that owing to the peculiar chemical change in the tissue requisite to the pathological alteration, as shown in mycosis so-called, the chemistry of the secretion is suitable to the growth of the leptothrix.—*Laryngoscope*, April, 1901.

The Discovery of the Cause of Malaria.—Dr. Louis Sambon, writing in the London *Practitioner*, says: "It is to Alphonse Laveran that the discovery of the malarial parasites is entirely due. It was in Algeria, while engaged as an army surgeon, that Laveran took up malarial pigment. He began his researches in 1879, and soon became aware that the pigment cells described by Meckel were living organisms, but it was only on November 6, 1880, that he was able to pronounce Eureka. On that memorable day he was, as usual, in the military hospital of Constantine patiently examining malarial blood. He had been a long while observing the peculiar ebullition-like turmoil of the pigment granules in one of the larger spherical bodies, when suddenly the cell projected several long, slender filaments, which began to wave about very actively, lashing and displacing the surrounding erythrocytes. There could be no further doubt as to the animate nature of these bodies, and Laveran sent a short note of his observations to the Paris Académie de Médecine, which was read at the meeting of November 23, 1880. Soon after he published a second paper, giving the points of difference between the malarial parasites and melaniferous leucocytes, and in 1881 he published a small illustrated monograph on 'La Nature Parasitaire des Accidents de l'Impaludisme.' In 1884 Laveran published his famous 'Traité des Fièvres Palustres.'"

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 Fifth Avenue.

New York, June 1, 1901.

PRELIMINARY REPORT OF THE COMMITTEE ON ORGANIZATION OF THE AMERICAN MEDICAL ASSOCIATION.

THIS report has just been published and provides ample material for reflection. Reforms are badly needed in matters medical in this country, and the praiseworthy object of the committee of the association is to pave the way for these most necessary changes by first putting in order its own house. The committee wisely premises its recommendations by the statement that, after due consideration of all the attendant circumstances, it early reached the conclusion that it would be useless at this late day to suggest the adoption of either half-way or compromise measures, consequently the proposed plan of campaign is thoroughly comprehensive.

The first recommendation made is that a business section be constituted, to be known as the House of Delegates, which shall proportionately represent the State societies in accordance with their numerical strength, with the addition also, as directly representative of the scientific work of the association, of one delegate from each section. It is suggested that the present representation for the State societies be fixed at one delegate to every five hundred members.

There can be little dissent from the proposition that the number of representative delegates is at the present time excessive, and that, instead of helping on the business of the association, they act rather as a cog in the wheel. When the association was founded conditions were altogether different; there were only about twenty-five thousand physicians in the United States, and the system of representation was fully equal to the demands of the situation, and continued to be so for a considerable time. Fifty-five years have now passed; there are one hundred and twenty thousand physicians and between thirteen and fourteen hundred regular medical societies, and still the original scheme of representation is in force. Such, certainly, is an anomalous state of affairs. For the reason alone that work will be expedited, this suggestion of the committee deserves the earnest support of the medical profession throughout the country.

But other reasons almost as convincing may be urged in favor of the recommendation. These are, that its adoption will prevent delegates from the States near the place of meeting from wielding a preponderating influence; that under the existing system a correct registration of delegates is practically impossible, in consequence of which many attend meetings and vote who are really ineligible; and that a large number of members are not interested in medico-political matters and perform the duties thereto pertaining in a perfunctory manner or probably wholly shirk them.

The committee summarizes the objections to the existing mode of representation as follows: 1. It is not representative. 2. It detracts from the scientific value of the annual meeting, wasting the time of those who are not interested in medico-political subjects. 3. The time devoted to the general sessions does not give opportunity for deliberate consideration of the living problems of the profession of our country. 4. The body as now constituted has become so large and unwieldy that it is impossible for it to transact business deliberately and calmly, and take up and consider the important questions affecting the medical profession.

The committee asserts, and undoubtedly with truth, that one hundred and fifty representative delegates will be a number quite adequate to transact the necessary business, and in proof of this statement draws attention to the fact that those societies which do the most effective work have invariably a small executive.

Before leaving the question of the business section, the conception of which is so excellent that we cannot but think it must impress medical men favorably, and which will doubtless carry their best wishes for its realization, it may not be out of place to make a suggestion, namely, that it might be in the interests of both the profession and the association if the annual meeting of that body were conducted in all departments upon more strictly business principles than have up to the present time prevailed. The next recommendation of the committee is for the uniform organization of both State and county medical societies, as being directly subsidiary to the plan outlined for the association itself. This also is a most important and radical proposed measure, the successful conduct of which will take much delicate and diplomatic handling. It is indeed the hinge upon which the whole question hangs. The committee in the argument appended to its report says: "No successful organization of the profession is possible without the mutual co-operation of the national and State societies." But will these societies consent to be virtually absorbed into the association?

In this connection it may seem somewhat ungracious to rake up old troubles; but the physicians of New York yet bear in mind that some years ago, in consequence of a disagreement upon a point of medical ethics, their State society was put under the ban of the association, and denied re-admittance into that body. That is now a dead issue, and if it can be clearly demonstrated that to have a successful organization of the profession the mutual co-operation of the national and State societies is essential, then the State society of New York will doubtless for the sake of the common weal consent to bury the hatchet forever and work loyally and harmoniously with the association. The aims of the organization committee as set forth in its

report are lofty, and if only they can be reached, the heartfelt gratitude of all American physicians will surely be its just due.

THE OPERATIVE TREATMENT OF RECTAL CANCER.

The problem of how to deal with rectal cancer has always been interesting to surgeons, and never so much so as at present when we seem to have established certain facts in regard to this form of malignant disease. It has long been known that the varieties of carcinoma observed in the rectum may be either of the epitheliomatous or of the adenomatous type, that the course in this part of the body has been rather less malignant than in most localities, and that many patients have lived for considerable periods when the dangers of sepsis and continued irritation have been obviated by colostomy. In one way the comparatively slow and insidious course of rectal carcinoma has been a drawback in the development of the surgical treatment of the disease, since this fact tends to make a late diagnosis frequent, often after very extensive infiltration.

The first requisite for the successful treatment of cancer of the rectum is an early diagnosis, and in the light of our present experience and with our present resources, we may say in passing that to treat malignant disease in any part of the body with success the very first thing the importance of which we must recognize is this same early diagnosis. In discussing the surgical treatment of this disease we should place in a separate class those cases which originate in an epitheliomatous ulcer in or near the anal muco-cutaneous border. These cases when not too extensive are treated by operative means quite different from those used in more typical cases in which the disease occupies an area beginning an inch or so above the sphincter and extending upward a variable distance. The ordinary case of carcinoma of the rectum belongs usually to this latter type, and most of the specially devised methods of operation are directed against cases representing this type. We may take it as proved that, in order to gain satisfactory access to the field of operation in the average case of rectal carcinoma, we must resort to some osteoplastic or bone-removing method of which that named after Kraske is the best known. There are several modifications of Kraske's original plan, but they all involve temporary or permanent removal of that portion of the sacrum below the third foramen, so that this part of the operation is pretty well established and needs no particular comment. Through the exposure afforded by this plan of operation, very extensive removals can be effected, and if the disease has not involved any tissue beyond the rectal wall, very complete extirpations can be accomplished, followed often by long periods of immunity. The technical difficulties of the operation consist largely in clearing away the disease anteriorly and in reaching its extreme upward limit, and later in preventing incontinence as much as possible. Carwardine, an English surgeon, has recently suggested (*British Medical Journal*, October 29, 1899) a slight modification in operative procedure, which ought to be serviceable in many instances. After the bone resection is complete, he does a linear proctotomy, extending as far upward as is necessary, and thus lays open the whole rectum. This affords a very complete exposure, and makes dissection much easier. The further work is done on the plan of the Whitehead operation for hemorrhoids.

The prevention of incontinence is an aspect of the question which, so far, is not in a satisfactory condition. The mechanical devices used to maintain obturation are all more or less imperfect, and the operative means of getting an artificial sphincteric control, when it has been necessary to remove the sphincter, are still far from satisfactory. However, much work is being done in this line, and we may hope for increasingly good results. The success of the operative treatment of rectal carcinoma depends upon early diagnosis, completeness of extirpation, and ability to restore some sort of intestinal control, and it is for the attainment of perfection in these particulars that we should work. There has been considerable discussion upon the desirability of preliminary colostomy, and at present the weight of authority is in favor of performing this operation in all cases requiring extensive extirpation, so as to avoid the dangers of infection and the discomforts of constipation.

SUGAR AS A FOOD.

One can, without much effort of memory, recall those days when physicians inveighed in grave terms against the use of sugar. Mothers were warned of the injury to the health of their offspring which would assuredly follow the consumption of sugar in any but the most sparing quantities.

Sugar was "heating"; it caused constipation, and required a large amount of gastric juice to digest it properly. Moreover, it affected injuriously the respiratory organs and favored the production of intestinal worms. Now, *nous avons changé tout cela*, and more enlightened views prevail. In various countries physicians became convinced of the errors of their ways, one of the first converts to the belief that sugar is a healthful food being Michel Levy, the well-known French hygienist. Proudhon and Cruveilhier supported these views, the former of whom was the author of the aphorism that "sugar constitutes the poor man's pharmacy," his pocket alone suffering.

At the present time sugar from being almost universally condemned has been advanced to a pedestal in the dietary list, and bids fair—unless due discretion be used in its consumption—to lead its lovers into excess with its consequent evil effects.

However, the truth that sugar is a valuable food cannot be gainsaid, and when, as stated recently in an editorial in the *Sun*, it is learned that its consumption has doubled for the world in fifteen years, and that in Great Britain is three times as great per capita as it was forty years ago, a good idea will be had of the appreciation with which the saccharine matter is regarded by the present generation. The *Sun* in the same editorial also refers to an interesting article by

Dr. H. Willoughby Gardner on the dietetic value of sugar, in which he points out that it is easily digested and absorbed into the system; it is readily stored up as glycogen, forming a reserve of force-producing material; it is in this form readily available when required; it becomes completely oxidized without any waste, and leaves no residue. Dr. Gardner, who is an enthusiast as regards the merits of sugar, attributes to the fact that the British people are the largest consumers of sugar in the world, the reason that they have so greatly increased in height, weight, and health in the past half-century.

The German army authorities in 1897 made some experiments with regard to the sustaining and invigorating properties of sugar, which proved conclusively that it is an adjunct to the soldier's diet of almost inestimable value. It was declared that a few lumps of sugar acted like a charm against fatigue as well as in quenching thirst. The British government followed the example set it by the Germans, and now provides its soldiers with 37 gm. of sugar daily. The result of the experiment has been most satisfactory in the South African campaign. Our army, too, in its revised ration scale is allowed a generous amount of sweet food, but the time of trial has not yet been long enough to pass judgment as to its effects, although there is no reason to doubt that the American soldier will assimilate sugar with as much benefit to his health as have his European fellows.

THE COST OF CRIME.

Mr. Eugene Smith, of New York, read a paper with the above title before the annual meeting of the National Prison Association, held at Cleveland, Ohio, in 1900, in which the question is reviewed chiefly from a monetary standpoint. Few persons grasp the significance and the far-reaching importance of crime regarded from any point of view; and although it may appear somewhat sordid to endeavor to arouse the interest of the general public in the subject from the pecuniary aspect, yet after all this is the phase of the matter which will appeal most closely to the ordinary individual. The science of penology has advanced, and the treatment of criminals is conducted upon much more intelligent and humane lines than ever before; but, notwithstanding this fact, the large mass of the population exhibits an apathetic indifference with regard to the system, and refuses to be instructed. According to Mr. Smith there are several explanations of this popular indifference. The mistaken belief that the subject is abstruse and beyond comprehension; incredulity as to the possibility of reforming criminals; aversion to the criminal as an enemy of mankind beyond the pale of sympathy; the idea that repression of crime is a function of government and outside the scope of individual responsibility—all these causes contribute to lead the public to dismiss the whole subject in favor of other matters believed to be more important.

The controlling cause, however, of the popular indifference, beyond all of those already mentioned, is the utter failure of the public to grasp the importance of the subject and to comprehend how enormous is the burden and how terrific the danger with which crime oppresses the world. It is therefore thought that if an estimate as approximate as possible is made of the cost of crime in dollars and cents, and if the general population is by these means impressed with a clear conviction that it is a question which closely concerns their own pockets, this apathy may give place to a practical interest. Of course to say unhesitatingly what share of public taxation is properly chargeable to crime is wholly impracticable, as crime exerts its influence to a greater or less extent upon every department of life.

Mr. Smith thinks the most hopeful method of reaching a near estimate to be that of analyzing the statistics of certain cities or towns where the figures are known to be accurate and complete; and when definite conclusions have been drawn from them, it may reasonably be inferred that the same conclusions apply to other cities and towns similarly situated. For this purpose typical cities, widely separate from each other, and each one the central point of a large section of country of which it is fairly represenative, have been selected, such as New York, Cleveland, Chicago, St. Louis, San Francisco, Richmond, Charleston, Savannah, and New Orleans.

The general result of an analysis of the fiscal reports of these cities is as follows: The cost of crime included in taxation in the city of New York gives an average charge of over $6 for each individual in its population; in San Francisco about $5; in the other cities named the per capita tax runs with slight variation from $3 to $3.50, including county taxation $4 to $4.50 for each inhabitant. The final computation of the annual cost of crime taxation in the United States is placed at the conservative figures given below: City and county taxation chargeable to crime—30,000,000 inhabitants of cities at per capita rate of $35, $105,000,000. Town and county taxation chargeable to crime—45,000,000 inhabitants of the open country at per capita rate of $1, $45,000,000. Federal and State taxation chargeable to crime—not less than $50,000,000. Total, $200,000,000. This sum, immense as it is, merely represents an outlay in the prevention of crime. Mr. Smith further estimates the annual income of criminals to average $400,000,000, which, added to the yearly taxation caused by crime, gives a total of $600,000,000. This amount almost makes the head reel, and should have the effect of convincing unthinking members of the community that it would be well if they were to insist upon prison reforms and upon the abolition of methods and abuses existing in many parts of the United States. We shall have criminals always with us, as we have the poor, but at the same time there can be no doubt that many sinners may be reclaimed from a life of crime by treatment conducted on scientific principles.

The continual occurrence of cases of smallpox in New York has called forth an earnest appeal from the health board for all unprotected persons to be vaccinated. In those districts in which this protection has been assured the disease has disappeared.

News of the Week.

Dr. John Duncan Emmet, formerly surgeon of the Sixty-ninth Regiment, N. G. S. N. Y., was recently elected lieutenant-colonel of the same regiment.

Dr. Vaughan on Women Physicians.—A correspondent from Kalamazoo, Mich., sends us a clipping from a local paper containing a denial from Dr. Victor C. Vaughan, of Ann Arbor, of the remarks derogatory to women physicians attributed to him in a recent alleged interview. Dr. Vaughan says he never made the statement attributed to him in the newspapers, or anything like it, and that the interview as published was false.

In Honor of Professor Hansen.—It is proposed to present Dr. G. Armauer Hansen, of Bergen, the discoverer of the bacillus of leprosy, with an international testimonial on the completion of his sixtieth year in July, 1901. For this purpose an appeal has been issued for subscriptions in amount from 10 to 20 marks ($2.50 to $5) to be sent to Dr. Sandberg, Bergen, Norway. The American members of the international committee are Dr. James Nevins Hyde, of Chicago, and James C. White, of Boston.

The Tribulations of Faith Curists.—A man named Pierson was recently convicted in White Plains, N. Y., of having violated the penal code by failing to provide medical attendance for his sixteen-months-old adopted daughter, who died from pneumonia through lack of proper care. Judge Lent sentenced him to pay a fine of $500 and to stand committed one day for each dollar until the fine is paid. Pierson refused to pay the fine, and so was sent to jail. Dowie, the Chicago "Zionist," was arrested in that city last week pursuant to the action of the coroner's jury, which has declared him "criminally responsible" for the death of a woman who was an inmate of Dowie's "Zion." Her infant also died. On testimony before the coroner that the ordinary treatment given by medical practitioners would probably have saved her life, her husband, her two nurses, and Dowie were held to await the action of the grand jury.

A Proposed Leper Hospital Burned.—The opposition to the establishment of a lazaretto on the Elkhorn Plantation, Jefferson Parish, Louisiana, which has been pronounced ever since the idea was first broached, culminated on May 23d in the burning of the plantation house just purchased by the board of control of the lepers' home. The lepers are now confined at Indian Camp, and it was but a few days ago that a delegation composed of the State senator from Jefferson, the district attorney, members of the police jury, the board of health, and others waited upon the leper board to protest against placing the hospital there. The matter was taken under advisement, but it was believed generally that the board would refuse to grant the request.

A Bequest to the Home for Consumptives.—Miss Maria Sprague Meeker, who died recently in Brooklyn, left her residuary estate to the Hospital for Breadwinners, which at the time of the execution of the will was about to be organized. If the hospital was not incorporated, the residuary estate, amounting to about $12,000, was to go to the Brooklyn Home for Consumptives. The Hospital for Breadwinners was not incorporated at the time of the death of Miss Meeker, and the surrogate decided that the residuary estate must go to the Home for Consumptives.

Dr. Robert Lewis, Jr., has been appointed aural surgeon to the New York Eye and Ear Infirmary.

The National Confederation of State Medical Examining and Licensing Boards will hold its eleventh annual meeting in the senate chamber of the Minnesota State capitol, St. Paul, on Monday morning and afternoon, June 3d. The president of the confederation is Dr. J. N. McCormack, of Bowling Green, Ky., and the secretary Dr. A. Walter Suiter, Herkimer, N. Y.

The Tuberculosis Congress.—The following are the names of the officers elected by the Congress on Tuberculosis recently held in this city: Dr. A. N. Bell, of New York, former president, *Honorary President;* Dr. Henry Holton, of Vermont, *President;* and Clark Bell, of New York, *Secretary and Treasurer.*

Tobacco Inconsistency.—The governor of Michigan has a cabinet whose members nearly all smoke large dark cigars without reproof from his excellency. Yet there is little doubt that the governor will sign the law making it criminal to sell or give away cigarettes. This is another example of swallowing the camel. In the State of Connecticut they do somewhat the same. In the school text-books the children are taught that a drop of nicotine will kill a full-grown cat in one minute, and that the smoker shuffles in his gait and loses ambition, and at the same time the same State spends $500 a year to encourage experiment in tobacco growing.—*The Medical Age.*

Dental Surgeons in the Army.—The following have been appointed contract dental surgeons in the army, in accordance with the provisions of the army reorganization law: John S. Marshall, Illinois; Robert T. Oliver, Indiana; Robert W. Morgan, Virginia; Emmet J. Craig, army; Samuel W. Hussey, army; Clarence Lauderdale, New York; S. Davis Boak, West Virginia; Franklin T. Wing, Montana; George L. Mason, Massachusetts; Hugo C. Rietz, Wisconsin; William H. Ware, California; Ralph W. Waddell, Ohio; Frank H. Wolven, New Jersey. These men are not commissioned by the President, but serve under three-year contracts made with the surgeon-general. They are not designated as officers, but wear the uniform of a first lieutenant, save that the braid on the shoulder straps is silver instead of gold.

Philadelphia Pediatric Society.—At a stated meeting held May 14th, Dr. Thomas Luther Coley read "A Report of Five Cases of Paralysis in Childhood," with exhibition of the patients. One of these was a case of cerebral hemiplegia, associated with epileptic convulsions in the sequence of some of which eyesight and the light-reflex of the pupil on the affected

side were abolished temporarily. The question arose as to the indication for surgical intervention. The remaining cases were instances of acute anterior poliomyelitis, two of which occurred in brothers, though not simultaneously. Dr. Augustus A. Eshner read a paper entitled "Nodding and Rotatory Spasm of the Head with Nystagmus in Rachitic Children." He reported two cases, one in a colored child in which the movements of the head were at times nodding and at other times rotatory, with sometimes lateral and sometimes vertical nystagmus; the second case was in a white child in which also the movements took place in both directions. The condition bears some analogy to spasmodic torticollis in adults, of which a case was reported. Dr. A. H. Davisson exhibited "A Case of Cretinism," and also "A Case of Microcephalus." Dr. James K. Young exhibited "A Case of Cured Lumbar Abscess in Pott's Disease," and he described the method of through-and-through drainage now generally employed. Dr. Henry R. Wharton exhibited "A Case of Stricture of the Œsophagus," resulting from the accidental swallowing of lye by a young colored child, in which relief was afforded by gastrostomy followed by retrograde dilatation by means of rubber tubing of progressively increasing size. Dr. William J. Taylor read a paper entitled "Œsophagotomy for Foreign Bodies in Children," detailing a case in which this operation was performed for the removal of a "drawer-clasp" that had been swallowed seven months previously and was located with the aid of a skiagraph. Dr. H. M. Shriner read the "Report of a Case of Enteric Fever with Hæmatemesis." Dr. D. J. M. Miller read "A Brief Report of a Case of Tænia Saginata in a Child of Twenty-four Months from the Use of Rare Scraped Beef for the Relief of Chronic Intestinal Disturbance."

The New York Academy of Medicine.—At the stated meeting to be held on Thursday evening, June 6th, there will be the presentation of the portrait of William H. Thomson, M.D., formerly president of the New York Academy of Medicine, by W. H. Polk, M.D. Also the following papers: "The Freezing-point of Urine; its Determination and the Inferences which May be Drawn from it," by J. H. Huddleston, M.D.; "The Early Recognition and Management of Arterial Degeneration," by Louis Faugères Bishop, M.D.

Camden County (N. J.) Medical Society.—At the annual meeting held at Camden, N. J., on May 14th, delegates to the American Medical Association, the New Jersey State Medical Society, and other medical societies were elected, as well as the following officers for the ensuing year: *President*, Dr. William R. Powell; *Vice-President*, Dr. J. Doron; *Secretary*, Dr. Paul M. Mecray; *Treasurer*, Dr. E. R. Ramsdell; *Historian*, Dr. H. H. Sherk; *Reporter*, Dr. J. Doron; *Standing Committee*, Drs. Charles Braddock, F. W. Marcy, J. Anson Smith, J. K. Bennett, C. G. Hoell; *Censor*, Dr. John R. Stevenson; *Trustees*, Drs. E. L. B. Godfrey, W. A. Davis; *Committee of Arrangements*, Drs. William H. Iszard, Sylvan G. Bushey, and John F. Leavitt.

New Medical Laboratories at the University of Pennsylvania.—The authorities of the University of Pennsylvania have projected new medical laboratories to be devoted to instruction in physiology, pathology, and pharmacodynamics. For this purpose there will be constructed a quadrangular building, two stories in height above a basement, three hundred and forty feet long by nearly two hundred feet deep. The first floor will be devoted to the branches of physiology and pharmacodynamics and the second floor exclusively to pathology. The entire front of the building will be occupied by laboratories, each thirty-one by forty-four feet, for advanced students. The east wing will be occupied by a laboratory of experimental pathology and the west wing by a museum, forty-four by sixty-five feet, for pathological specimens. There will also be a hall for demonstrations in morbid anatomy, and a pathological histological laboratory thirty-seven by one hundred feet in size, with a front almost entirely of glass, facing north upon a spacious court, and seating one hundred students. It will be especially adapted for microscopical work. There will also be laboratories for instruction in comparative pathology, neurological pathology, and surgical pathology. Four lecture rooms are to be provided, two of which will accommodate one hundred and eighty-five students each, and the other two four hundred each. The building is to be but one of a group for the teaching of medicine, the construction of which is contemplated by the trustees. This group will include a new medical hall, an anatomical building, and auxiliary buildings.

The Library of the Kings County Medical Society.—This excellent library was founded in 1845. Its first home was at 356 Bridge Street. When these quarters became inadequate, the society erected a fireproof structure at 1313 Bedford Avenue. On May 19, 1900, the library of over 30,000 volumes, 15,000 pamphlets, and some 500 current medical periodicals was throw open free to the public. In addition to the latest publications, the collection is especially rich in classics. The earliest printed volume is a folio published A.D. 1474. The first donation to the permanent invested endowment was the "Dr. John Lloyd Zabriskie Memorial Library Fund," presented in 1899 by Mrs. Zabriskie as a memorial of her husband, the late Dr. John Lloyd Zabriskie. The library is open free to the public daily, except Sundays and legal holidays, from 10 A.M. to 10 P.M., and books are loaned to members of the Kings County Society and of other affiliated societies of Long Island. The officers of the library have recently issued an appeal for contributions to the endowment fund and for gifts of medical books and journals.

"Vratch."—Dr. Viatcheslav Manasseïn, the editor and proprietor of *Vratch*, the leading Russian medical weekly, died a few weeks ago. A year or two before his death he gave explicit directions that whenever he should die the publication of his journal should be continued only to the end of the current year. The journal, an excellent publication and a model of its

class, has been in existence seventy-one years, and it is to be hoped that it will not be allowed to die in consequence of Dr. Manasseïn's curious whim, or at least that some one will establish a new journal on the same lines which will continue the work where *Vratch* drops it.

Decrease in the Consumption of Absinthe in France.—As an immediate result of the new French liquor law greatly decreasing the taxes on wines and ciders, the consumption of these increased fifty per cent. during the first four months of the year, the drinking of white wine having largely replaced the use of absinthe.

A League against Syphilis.—As an outcome of the Congress on the Prophylaxis of Syphilis held in Brussels in 1899, a league against syphilis has recently been founded in Paris. The president is Professor Fournier; the vice-presidents are Drs. Bérenger, Brissaud, and Le Pileur. Dr. Barthélemy is secretary-general.

The Staten Island Ambulance.—An effort is being made by citizens of Richmond Borough to compel the S. R. Smith Infirmary, the only charitable hospital on Staten Island, to inaugurate an ambulance service. The hospital receives an annual appropriation from the city for the care of the sick, and it owns an ambulance which was donated to the institution some years ago. The horse died, however, and has never been replaced. At present patients are removed to the hospital in a police wagon.

Philadelphia County Medical Society. — At a stated meeting held May 22d, Dr. John H. Musser delivered the annual address of the retiring president, taking for his subject "Streptothrix Infections." He reviewed the comparatively scanty literature of the subject, and reported two cases that came under his personal observation. In one of these there were at first symptoms merely of bronchitis, but eventually those of broncho-pneumonia, with elevation of temperature, were superadded. Examination of the scanty sputum obtainable at this time disclosed the presence of streptothrices and streptococci. Death took place, but post-mortem examination could not be secured. In the second case there had been loss of consciousness with convulsive seizures, followed by unilateral hyperæsthesia. A tuberculous lesion of the brain of undeterminable situation was thought to be present, but upon post-mortem examination an abscess was found in the left Rolandic area, the contents of which were found to be sterile, except for the presence of streptothrices, which were detected in the pus and in the walls of the abscesses in but small number and only after the examination of large numbers of preparations.

The King and the Doctors.—The Prince of Wales was last year elected an honorary member of the British Medical Association as well as a fellow of the Royal College of Physicians and Surgeons. It appears, however, that in the passage from prince to king such honorary memberships lapse, and the king has refused to enter the association again. But he has softened the sting of refusal by consenting to be a patron, which is taken by his loyal subjects to indicate that he does not disapprove of the work of the association.

Mumps in Central America.—Nearly every part of the Central American states has been visited recently by mumps of quite a severe type. The disease has occurred not only as parotiditis, but frequently also as orchitis, metastasis to the testicles being quite common.

The Colorado State Medical Society.—The next annual meeting of this society will be held in Denver on June 18, 19, and 20, 1901. Among the special features will be a series of papers on the history of medicine in Colorado, and a symposium on diseases of the kidneys.

A Collective Investigation of Cancer in Russia.—The Russian government has undertaken to collect statistics regarding the prevalence of cancer in all parts of the empire. The cancer census paper, besides asking for information about the antecedents—personal, hereditary, and collateral—of cancerous persons, also demands facts concerning birthplace, habitual residence, pecuniary means, use of tobacco, diet, drinks, etc. It is thought that it will be possible to compile a cancer map of the country, showing that the disease is practically confined to certain districts.

Texas Fever in Germany.—According to a despatch to *The Sun* from Berlin, a German medical weekly announces that Dr. Ziemann has discovered Texas fever in north Germany. Heretofore the disease has been known only in Texas, Roumania, Finland, and Sardinia. Dr. Ziemann has identified a cattle disease prevailing in the Neuenburg district of Oldenburg with Texas fever. It has been known under a local name for at least one hundred years throughout Ammerland district. The local veterinary surgeons thought the disease was the result of poisoning by a certain weed growing in the district.

Female Medical Practitioners in Germany.—One of the first ladies who have taken advantage of the recent relaxation of the rule excluding women from the study of medicine in Germany is Fräulein Mathilde Wagner, of Frankfort, who has just passed the final examination in medicine at Freiburg-in-Baden. She received her certificate of "maturity" in Berlin some years ago, studied medicine at Zurich, passed her first examination there, and was about to take her final one last autumn, when it became possible for her to obtain a license in her native land. She is now at liberty to practise medicine in Germany. Six ladies graduated at German universities last winter, and others are about to follow their example.—*British Medical Journal.*

The Mississippi Valley Medical Association.—It is announced that the dates of the next meeting of the Mississippi Valley Medical Association have been changed from the 10th, 11th, and 12th of September

to the 12th, 13th, and 14th of September. This change has been made necessary because the dates first selected conflicted with those of another association meeting at the same place. The meeting is to be held at the Hotel Victory, Put-in-Bay Island, Lake Erie, O., and the low rate of one cent a mile for the round trip will be in effect for the meeting. Tickets will be on sale as late as September 12th, good for returning without extension until September 15th. By depositing tickets with the joint agent at Cleveland and paying fifty cents, the date can be extended until October 8th. This gives members an opportunity of visiting the Pan-American Exposition at Buffalo, to which very low rates by rail and water will be in effect from Cleveland. Full information as to rates can be obtained by addressing the secretary, Dr. Henry E. Tuley, No. 111 West Kentucky Street, Louisville, Ky. Members of the profession are cordially invited to attend this meeting. Those desiring to read papers should notify the secretary at an early date.

The Philadelphia Medical Club tendered a reception on May 23d to Dr. Walter Wyman, supervising surgeon-general of the United States Marine-Hospital service.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending May 25, 1901. Passed Assistant Surgeon R. M. Kennedy ordered home by public conveyance. Assistant Surgeon M. V. Stone detached from the *Buffalo* and ordered home to await orders. Assistant Surgeon C. H. DeLancy detached from the *Bancroft* and ordered to the *Buffalo*. Assistant Surgeons F. M. Furlong, D. B. Kerr, E. J. Grow, A. G. Grunwell, D. G. Beebe, and C. D. Langhorne ordered home by public conveyance. Assistant Surgeon J. Stepp detached from the *Castine* and ordered to the *Isla de Luzon*. Assistant Surgeon E. J. Grow detached from the *Isla de Luzon* and ordered to the *Castine*. Assistant Surgeon E. Thompson detached from the *Solace* and ordered to the *Petrel*. Assistant Surgeon R. W. Plummer detached from the *Petrel* and ordered to the *Nashville*. Assistant Surgeon F. M. Furlong detached from the *Brutus* and ordered forward to Guam, Leeward Islands.

Pathological Society of Philadelphia.—At a stated meeting held May 23d, Dr. M. P. Ravenel exhibited specimens of "Scabies in Rats." The condition is a form of mange, and is due as in man to a variety of sarcoptes. The ears, the tips of the nose, and the tails were affected. Dr. Ravenel exhibited also "Unusual Types of the Tubercle Bacillus." One of these was of the bovine variety, secreting an unusually large amount of fat. Two others were cultures of human tubercle bacilli, displaying chromogenic properties when grown on dog-serum medium. Drs. W. M. Welch and J. F. Schamberg exhibited "Specimens from a Case of Variola." The patient had been a young unvaccinated white man, in whom the cutaneous lesions had been widespread and in part confluent. Death occurred in the stage of suppuration. In addition to a segment of skin and sections through the lesions, the greatly injected stomach and the œsophagus containing a few lesions were demonstrated. Dr. R. M. Pearce presented a communication on "The Increase of Connective Tissue in the Lung in Chronic Passive Congestion." He demonstrated an increase of elastic tissue in the walls of the bronchioles, the vestibules, the alveoli, and the air-vesicles, the purpose of which it was thought was to give support to the capillary blood-vessels. Drs. F. A. Packard and S. Flexner exhibited specimens from "A Case of Probable Primary Intestinal Tuberculosis in an Adult with Multiple Metastases." The case was one in which cerebro-spinal meningitis had been suspected during life, but post-mortem examination revealed a small area of old fibrous tuberculosis of the lung and adjacent pleura, with hyperplastic and obliterative tuberculosis of the vermiform appendix, slight tuberculosis of the adjacent ileum, and tubercles on the serous coat of the bladder, together with a large tubercle in the optic thalamus on one side, old tubercles of the choroid plexus, and recent miliary tubercles of the pia at the base of the brain. Dr. W. F. Hendrickson exhibited a specimen of "Teratoma of the Testicle" removed surgically. Drs. W. S. Wadsworth and W. F. Hendrickson exhibited a specimen of "Tuberculosis of the Heart," obtained from a man who had died suddenly. A large tubercle was situated in the wall of the left ventricle, and smaller tubercles were present in other situations in the myocardium.

Physicians in Conflict with the Health Board.—Proceedings were recently instituted by the health department of this city against two physicians who are accused of having failed to report cases of smallpox under their care.

An Experiment in Human Stirpiculture in France.—A despatch to *The Sun* announces that the Count de Pierrecourt, who recently died without any heirs, left the greater part of his fortune, said to amount to 10,000,000 francs, to his native city of Rouen on condition that an annual prize of 100,000 francs be founded to form a settlement for the tallest man and woman who agree to marry each other. The count's object, as stated in his will, is to regenerate the species.

Census of Samoan Islands.—The Associated Press reports that a census of the Samoan group has been taken. The number of Samoans in Upohe and other islands under the German government is 32,000, while the population of the six islands under the United States government is returned at 5,800. The slight increase in the past thirty years is about the same in proportion all round. The infant mortality is greatest, and this is due in a large measure to the ignorance and carelessness in dieting the young. It is only since the United States took possession that people have been able to receive medical advice and treatment. With the sanitary laws now in force, and the laws concerning the health of the people generally throughout the island, it is hoped that in the next decade there will be a considerable increase of the native population.

Obituary Notes.—Dr. Alonzo C. Casler died at his home in St. Johnsville, N. Y., on May 11th, of tuberculosis. He was a graduate of the Albany Medical College in the class of 1880.

Dr. Henry D. Whitbeck, for many years a practising physician in Auburn, died recently at the Soldiers' Home Hospital, at Bath. He served in the Civil War in Company A, Ninety-eighth Regiment, New York Infantry.

Dr. John A. Wells, of Englewood, N. J., is dead. He was born in 1856 in this city, and was a graduate in arts from Yale in the class of 1876. After graduation in medicine from the College of Physicians and Surgeons in 1879, he began practice in New York, but removed to Englewood in 1883. Dr. Wells was keenly interested in improving the sanitary condition of Englewood, and was largely instrumental in establishing and maintaining the Englewood Hospital, of which he was house surgeon. He was a member of the Medical Society of Bergen County. He was an enthusiastic sportsman, being particularly devoted to shooting, fishing, and golf. He was a member of the executive committee and one of the board of governors of the Englewood Golf Club, in which he always took an active and leading part.

Dr. Thomas F. Rumbold, of St. Louis, died on May 23d at the age of seventy-one years. He was born in Scotland, but came to this country in early life. He was a graduate of the Jefferson Medical College in 1862. He was a laryngologist and rhinologist of much repute.

Dr. Conrad Wienges died at his home in Jersey City on May 23d at the age of fifty-three years. He was born in Charleston, S. C., and was a graduate of the College of Physicians and Surgeons, New York, in the class of 1883.

Progress of Medical Science.

The Medical News, May 25, 1901.

Tuberculosis of the Iris.—William F. Mittendorf states that there is close conuection between tuberculous affections of the eye and pulmonary or general tuberculosis. The iris and choroid are much more frequently invaded than any other part of the eye. The starting-point of the tuberculous iritis may be in the iris or in the ciliary body or the choroid, but it soon spreads, and the entire eyeball is apt to become involved. It is sometimes primary but usually secondary. There are the solitary and the multiple forms, and the latter may be acute or chronic. Generally it is a disease of youth or early middle life, and nearly always only one eye is affected. The first class described comprises those cases which are usually connected, more or less directly, with tuberculous disease of the general system. One or more grayish nodules develop in the iris, with intense pain in the eye and forehead; many synechiæ form; the eyeball becomes red and painful to the touch, and the disease resembles in many respects an acute attack of rheumatic or specific iritis. Gradually the whole eyeball becomes involved. Another form of tuberculous disease of the iris, which is not so violent in its onset, occurs usually during the earlier stages of pulmonary tuberculosis. This is characterized by multiple tuberculous deposits in the iris. There are pain and photophobia and more or less invasion of the papillary border of the iris which leads to the formation of posterior synechiæ. This is much slower than the first form, and there is not usually much change in the appearance of the eye. The third form shows itself in the shape of a single tuberculous deposit at the bottom of the anterior chamber, projecting into the aqueous humor and frequently involving the ciliary body from the outset. As a rule the eye will have to be enucleated. Treatment should be that employed for tuberculosis in general, *e.g.*, creosote. Atropine solution, gr. iv. or vi. to the ounce of water, is most valuable for the iritis or irido-cystitis. Morphine may be given for great pain. If the disease appears to be progressive in spite of the usual remedies, the eye must be completely removed.

Municipal Care of the Consumptive Poor.—S. A. Knopf urges the establishment of sanatoria for poor tuberculous patients. Pure air, sunshine, good food, and constant medical supervision cannot be obtained in tenement houses, and in general hospitals the risk of infection for the other patients is too great. Tuberculosis in early recognized cases has fifty to eighty per cent. of chances of cure. In special sanatoria, moreover, training is given as to prevention of colds, and treatment of accidents which may occur in the course of the disease. That sanatoria would be appreciated is shown by the statistics of the Rutland Sanatorium, which in one year had 1,233 applicants, of whom fifty-nine per cent. were turned away for lack of room or too advanced condition of the disease. Some fear contagion from a sanatorium, but the records of over fifty years for the towns of Goerbersdorf and Falkenstein, where there are five sanatoria, show that the mortality from tuberculosis has been decreased to one-third of what it was before the establishment of the institutions.

Nasal Conditions Observed in the Aged.—Beaman Douglass has examined a number of persons, forty-five years or more of age, with a view to determine the presence or absence of nasal lesions in advanced life. He was led to this by the casual observation that individuals more than fifty years of age seldom applied for treatment of nasal troubles. He found that, while elderly persons not uncommonly had nasal lesions of one sort or another, these seldom produced symptoms of sufficient intensity to lead the subjects to seek medical advice. He suggests that this may be explained on two hypotheses: that the physiological activity of the nose has been increased so as to overcome the damage from the lesions; or that the lesion, with its resultiug discharge and reflex pain, is in some way less active, and allows the nose to resume its physiological functions.

Antistreptococcus Serum in Two Cases of Puerperal Septic Infection.—A. J. Primrose reports two cases in which there was prompt subsidence of septic symptoms on the use of antistreptococcus-serum injections.

On the Use of Alcohol in the Treatment of Carbolic-Acid Burns and Poisoning.—F. Pirkner relates how Powell demonstrated his discovery that alcohol is an antidote to carbolic acid. He filled his mouth with pure carbolic acid, allowing it to remain thirty seconds; he then filled his mouth with pure alcohol, and suffered no bad results whatever. The writer rubbed some pure carbolic acid into the skin of his right hand so as to cause a local dermatitis. Two minutes afterward he bathed the spot with eighty-per-cent. alcohol, which relieved the pain immediately. Alcohol is an antidote to carbolic-acid poisoning; this is not so well known as the fact that alcohol is a safe and sure

specific against the escharotic action of pure carbolic acid. In order to obtain the best effects when used as an internal antidote, the administration of the alcohol must be made as soon as possible after the ingestion of the acid.

An Overlooked Nasal Factor in Ear Disease.—Chevalier Jackson says that this condition consists of hypertrophic thickenings usually on both sides of the vomer near the posterior free margin, which deflect the in-rushing blast of dust-laden, dry, cold air against the Eustachian orifices, resulting in constant irritation of the mucous membrane in the vicinity of the tube mouths. The growths are soft but only partially erectile. They have been present in twenty-five per cent. of the writer's private ear cases and in eleven per cent. of dispensary nose and throat cases. Removal is obviously called for, together with that of posterior turbinal hypertrophies. For this purpose, either a Bryan's ethmoid curette, Reiss' curette, or a long-shanked tube-pointed tenotome will answer.

Tuberculosis of Fascia.—By J. C. Stewart. The following are the author's conclusions: (1) Tuberculosis of the fascia occurs with sufficient frequency to entitle it to more attention than it has received in the past. (2) It occurs in two well-marked forms. (3) The recognition of these forms is essential to its proper surgical treatment. (4) Fibrous tissue associated with, and resulting from, tuberculous infection is to be viewed as tuberculous tissue and treated accordingly. (5) Such fibrous tissue may in some cases need the test of animal inoculation absolutely to prove its tuberculous character.

Two Cases of Lobar Pneumonia following Ether Anæsthesia, with Unusual Course.—W. S. Schley reports these two cases: the pneumonia in one occurred after the administration of ether for ventral suspension of the uterus; in the other, for herniotomy. There was nothing remarkable in anæsthesia, operation, or condition of patient preceding operation. Both cases, however, developed typical lobar pneumonia upon the first and third days, respectively, following operation. In each case the right lower lobe was the portion of lung involved. There was in both cases subsidence of temperature within sixteen hours, and beginning resolution within two days after the administration of a single large dose of calomel (gr. xx. to xxv.). The mercury was given within sixteen hours of the initial rise of temperature, and dry on the tongue. These were the only cases of pneumonia occurring in the surgical division of the hospital (St. Luke's) after several thousand anæsthesias extending over a period of about two and a half years. The use of mercury in this connection is very old. There is reason to believe that a certain number of patients have been benefited by such treatment. A large class undoubtedly will not be.

Trauma as an Exciting Cause of Paralysis Agitans.—F. Savary Pearce concludes that the later the origin of the disease, the more apt is trauma to have been the exciting cause. In any event it is more apt to produce an aberrant type of the malady, especially when the insult to the nervous system has been primarily in the periphery of the body rather than of the central neurons. Treatment would differ essentially in one particular to obtain better results of therapeutics. Nerve stretching seems to be a rational procedure in cases as here reported, when the tremor is localized, and especially when reflex origin below the cerebrum seems to be pretty definitely the cause of the irritation of the motor neurons.

The Surgical Treatment of Chronic Ulcer of the Stomach.—By A. W. Mayo Robson.

The Lancet, May 18, 1901.

Is the Murmur of Mitral Stenosis Systolic or Presystolic in Rhythm?—Hugh Walsham says that his belief that the murmur of mitral stenosis was presystolic in rhythm was shaken, though not destroyed, some years ago by a paper on "The Presystolic Murmur, Falsely so Called," by Dr. W. H. Dickinson. With the introduction of the Roentgen rays as a diagnostic aid in medicine he began a new series of investigations, and has satisfied himself by an ocular demonstration that the murmur is really presystolic. He says that, in a well-marked case of so-called pure mitral stenosis, if the hand be placed over the precordial region at the point of maximum intensity of the thrill (and this can be done without obliterating the shadow of the heart on the screen) and the cardiac shadow be watched, one finds that the thrill corresponds to the advance of the left border of the shadow of the heart to the left and ends abruptly with the retreat of the shadow toward the median line—that is to say, the thrill is obviously presystolic in rhythm and ends with the systole. It begins with the advance of the left border of the cardiac shadow to the left—that is, during the auricular systole—and ends with the retreat of the shadow toward the middle line—that is to say, with the ventricular systole. Again, if while one is watching the heart with the screen, the chest-piece of a binaural stethoscope be placed on the screen at the point of maximum intensity of the murmur (previously determined) it will be found that the murmur begins at the moment when the shadow of the left ventricle is advancing to the left—that is, during the auricular systole—and ends abruptly when the shadow retreats toward the middle line—that is, with the ventricular systole. The author says he has examined a good many cases of pure mitral stenosis with reference to this point, and has convinced himself that the thrill and murmur are truly presystolic in rhythm.

Opotheraphy in Gynæcology.—John Phillips speaks of the effects of three of the many animal extracts more or less extensively used in gynæcological practice, viz., thyroid, ovarian, and mammary gland. Of the first only he speaks with any confidence; this he says is certainly of value in amenorrhœa accompanying extreme obesity and myxœdema. It is said also by some to be beneficial in metrorrhagia complicating fibroid tumors. Ovarian extract the author has given in many diseases, but in none has he obtained any satisfactory results except possibly in cases of natural and artificially induced menopause. The use of mammary extract has produced no effects, good or bad, beyond a suspicion of improvement in lactation during its administration.

British Medical Journal, May 18, 1901.

Some Remarks upon an Analysis of Five Thousand Cases of Death from Malignant Disease.—E. N. Nason speaks first as to the proportion of cases occurring in the two sexes. Of 5,000 cases, 1,837 were males and 3,018 females (in 145 the sex was not stated). Of all the female cases it is found that in forty per cent. it is either the uterus or the breast that is affected, so that the excess of female cases is due to the fact that the female possesses these two special organs, and not to the greater tendency to cancer in the female. If the sexual peculiarities of both sexes be eliminated, the male is found to be the more often affected, in the proportion of about fifty-three to forty-seven per cent. Trauma

and syphilis, the important predisposing causes to cancer, come into the life of man far more frequently than in that of woman. During the last thirty years there has been noted a remarkable and steady increase in the general cancer mortality, but this increase is greater in the case of males than of females. One reason for this is probably the increased care and skill in diagnosis, as well as the great advance in the surgical treatment of cancer of the uterus and breast. About three-quarters of all the cases of cancer in the male occur in the alimentary tract. As to age, the liability to cancer of the stomach between the ages of fifty-one and sixty is exactly one-half what it is between the ages of seventy-one and eighty, the liability to cancer of the breast a little less than one-half, and that to cancer of the rectum only one-third. In regard to the uterus, the maximum liability is reached immediately after the cessation of functional activity, and the later years of life are associated with a considerably lessened liability to cancer of the uterus. Certain studies in this subject have shown that owing to the great difficulty of diagnosis in many cases of internal cancer the death rate from cancer is probably at present underestimated. Contamination of the soil or subsoil for long periods with decomposing organic matter is very probably a factor in the production of a high death rate from cancer. A damp, ill-drained, waterlogged soil is more often associated with a high cancer death rate than is a dry, well-drained soil. There is abundant evidence of the existence of groups of houses in which cancer is found with marked frequency. Cancer occurs more frequently in old than in new houses and districts. Under certain circumstances cancer may possibly be transmitted from one person to another in constant close association. The writer believes the following to be some of the more certain predisposing causes: (1) Prolonged local irritation, due to various causes, setting up local inflammatory changes in the irritated tissue. (2) The immediate or after-effects of direct and sudden injury, whether mechanical, thermal, or chemical. (3) Syphilis and possibly other constitutional diseases which are associated with local tissue changes. (4) The tissue degenerations of advancing years varying with age. (5) Individual proclivity. (6) The presence of fœtal remnants or "cell rests." If a specific parasitic organism exist, how does it gain entrance into the body? This might take place in one of several ways: (1) Absorption from the intestinal tract. (2) Absorption from the respiratory tract. (3) Direct inoculation, (*a*) through abrasion of skin or mucous membrane, (*b*) by the bites of blood-sucking insects.

Erythema Multiforme and Vaccination.—Norman Walker has observed several cases of erythema multiforme closely resembling smallpox. All of these cases had been recently vaccinated, and all showed features which seem to make it certain that the vaccination was causally related to the eruption. In one striking case, the hands presented an absolutely typical picture of erythema iris. The legs were also affected. The eruption spread up the arm beyond the usual limitation of erythema iris. The vaccination lesions presented an appearance quite out of keeping with the time which had passed since the operation was performed. Although a month had elapsed, the scabs were still moist, and they were surrounded by a raised erythematous patch of the same character as the eruption elsewhere. All of these cases were vaccinated with glycerinated lymph, and in all of them the early course of the vaccination was uneventful. The eruption developed always on the hands and the face, but on other parts as well. At the same time the vaccination area showed evidence of fresh activity. The course of the erythema was uneventful, the eruption rapidly disappearing.

Triplets with Single Placenta.—E. Barnes reports this case. This was the seventh or eighth pregnancy of the mother. The children were in full time, and consisted of two boys and one girl; a boy first, vertex presenting; then the girl, with the breech presenting; and then a boy with vertex, and a large single placenta.

Contribution to the Study of Pernicious Comatose Fever.—Jean P. Cardamatis believes that pernicious comatose fever, which is one of the malignant forms of malaria, is without doubt the most frequent type and the most dangerous manifestation of paludism. He is speaking in regard to his own country, Greece. This type of fever ordinarily makes its appearance in July, perhaps even in June, increasing in frequency during the autumn and becoming more rare in the winter. The predisposing causes are debilitated states of the organism, such as anæmia, the cachexias, the different pathological conditions, physical and intellectual fatigue, alcoholism, etc. There are two principal forms of this fever, the mild and the severe. The former consists of an increase in severity of the symptoms of the intermittent form of malarial fever; the latter is characterized by the complete abolition of consciousness, and it menaces the life of the victim with imminent danger. Every trouble of the nervous system which is noticed in the last stages of a simple intermittent fever, as for example the tendency to sleep, should be considered a prodromal phenomenon. Debilitated states of the organism may be the cause of the evolution of a simple intermittent fever into the comatose form. In this latter form the temperature varies ordinarily from 38.5 to 40°; it rarely reaches 41°, and still less frequently the condition of hyperthermia. In every case in which a differential diagnosis has to be made between this fever and sunstroke, when the temperature is above 41°, and when a microscopical examination is not possible, the case ought to be diagnosed sunstroke rather than comatose fever. In order to establish a certain diagnosis the former condition of the patient must be known, since sunstroke occurs very suddenly, in the midst of health, while comatose fever never attacks one who has not suffered from malaria. The prognosis of pernicious comatose fever depends on various conditions. Under favorable conditions, for example, when prompt treatment is instituted, mortality is decreased to about twenty per cent.; in unfavorable conditions it is increased to about fifty per cent.—*Progrès Médical*, April 20, 1901.

Note on the Treatment of Leprosy by Ichthyol.—H. de Brun gives his experience in the use of this drug in leprosy. It was in February, 1898, that he first gave it internally in a case of leprosy. The patient was a young woman aged twenty-four years, who had suffered from tuberculous leprosy for four or five years. The administration of the drug was begun in very small doses (0.30 cgm. of ichthyol a day), and the results were remarkable. In a few months the tubercles which disfigured the patient disappeared, and the ulcerating rhinitis decreased to such an extent that the writer hardly recognized the patient in October, when he saw her. From that time he gave ichthyol to all of his leprous patients, with the most surprising and gratifying results in cutaneous leprosy. In the nervous form, however, its results were *nil*. The difference in its action was most clearly shown in a mixed case which came under the observation of the writer. After four months of treatment by the internal administration of ichthyol in doses of 1 gm. increasing up to 6, 8, and 10 gm. a day, the leprous rhinitis, of which the patient complained almost exclusively on her entrance to the hospital, was absolutely cured. Rhinoscopical examination showed that everywhere the nasal mucosa was rosy and healthy, and that there was no infiltration nor ulceration. On the contrary, the nervous symptoms persisted with no attenuation. The dose may be begun at 5 gm. without fear. It may be gradually increased. The author has not obtained results from the external or topical application of ichthyol as advised by some authors.—*La Médecine Moderne*, April 24, 1901.

Resection of Gasserian Ganglion for Facial Neuralgia.—M. G. Marchant reports a case operated on by M. Bouglé, which had not yielded to numerous methods of treatment, not to mention the extraction of several teeth. The operation was performed by the temporosphenoidal route. It was easily accomplished and almost the entire ganglion was removed. The recovery was satisfactory, the only drawback being the development of an ulcer of the cornea with hypopyon. Vision was interfered with for some days, but little by little it returned, and at the end of some months the cure was complete. The writer has seen such happy results from the surgical treatment of cases of this kind that he wonders if it would not be well to adopt this line of treatment in the future instead of attempting every other known means first.—*Le Bulletin Médical*, April 29, 1901.

Treatment of Paralytic Luxation of the Shoulder.—Bothezat thinks that in difficult cases three methods of investigation should be tried. Electrical examination should be most minutely tried. It should be made several times, and ought to include all of the muscles of the paralyzed member. The duration of the paralysis should be precisely determined. When the paralysis is undoubtedly of three years' standing, one can count on its being incurable by medical treatment. If with these data the degeneration does not seem to be sufficiently demonstrated, a third means should be utilized—the medical treatment of paralysis. By the electrical treatment it can be learned with

certainty whether the muscles are of any further use or whether they are absolutely useless.—*La Presse Médicale*, May 1, 1901.

Münchener med. Wochenschrift, May 7, 1901.

The Symptomatology of Rheumatism (Tendinitis Rheumatica Ocularis).—A. Pichler gives the history of a patient who for fifteen years had been suffering from typical articular and muscular rheumatism, and who had for four years been affected by an apparent localization of the rheumatic diathesis in his eyes. The general attacks presented nothing of interest, occurred at frequent intervals, and never involved the eyes in the least, till suddenly, together with the usual general symptoms, the sclera of both eyes became infiltrated and reddened, and a painful swelling developed over the insertion of the inferior rectus. The subsequent attacks were always accompanied by these ocular manifestations, which sometimes were much more severe and involved the insertions of all the recti. The conjunctiva, iris, and ciliary body exhibited no changes, and there was never any mucous or purulent secretion. Several similar cases have been reported, and the author considers the affection sufficiently clear cut to justify the erection of a new clinical heading: "tendinitis rheumatica ocularis."

The Diagnosis of Frontal Tumor.—Höniger details the histories of three cases of new growth in the frontal lobes, the diagnosis being confirmed by autopsy in one instance. The conclusions to be drawn are that localization in the frontal region is to be suspected when a new growth of the brain is from the first accompanied by psychic manifestations, or when such develop in the course of the malady. The diagnosis becomes positive only when frontal ataxia, convulsions of the trunk musculature, and disorders of speech occur as focal symptoms, and motor affections or involvement of the basal nerves and ganglia, according to the line of growth taken, appear secondarily. The tendency to make puns and jokes is peculiarly characteristic of new growths located in this region, and is to be explained by the stimulation of the speech centre, and hence is most often observed when the lesion is left-sided.

Phototherapy with Ultra-Violet Rays.—Görl refers to the work of Finsen, who concentrates sunlight with large glass lenses, and the arc light through lenses of quartz, in order to obtain his bactericidal light rays. Inasmuch as doubt has been cast on the propriety of interposing the water cells which serve to absorb the useless yellow and red heat rays, but are alleged also to cut off the whole or a portion of the violet rays, the author has been conducting experiments taking the induction spark as a non-heating source of light. Healthy skin exposed for one hour reacted by hyperæmia, itching, desquamation, and permanent pigmentation, while two cases of lupus were apparently cured.

Pernicious Anæmia.—Rumpf, after mentioning the various conditions that have been supposed to underlie this disease, such as the presence of intestinal parasites, pregnancy and labor, syphilis, malnutrition, and disease of the stomach, and particularly of the intestinal tract, goes on to state his opinion that the belief in the infectious nature of the trouble, founded on the finding of small rounded motile bodies in the blood, is not justified, as, together with Hayem, he considers that these are not micro-organisms, but microcytes. Chemical analyses of the blood in this condition have been but few, and the author gives the result of several such investigations made by him. The most noteworthy facts presented by these figures are the high water percentage of the blood with a low amount of solids, the large chlorine figure, and diminished potassium, iron, and fat. Analyses were also made of some of the internal organs, such as the liver, heart, brain, and spleen, with the general result that while the liver was richer in potassium than usual, the organism as a whole is very deficient in this metal as well as in fat, while the chlorides are correspondingly high. The poverty in potassium may be ascribed to the destruction of so large a proportion of the red cells with the consequent excretion of the potassium thus set free, or it may be explained by a somewhat more complicated hypothesis. If pernicious anæmia is dependent on excessive red-cell destruction, with a relative insufficience of the hæmogenetic organs, and if this degeneration is also accompanied by the formation of toxic principles, it is possible that these toxins may have some relationship to the potassium of the red cells, and that the removal of this element may be followed by the cellular degeneration. If this assumption is correct, the administration of absorbable potassium combinations ought to be of great value in the treatment, and so the author has found it, as is shown by the histories of four cases in which permanent cure has followed the use of this plan of treatment. The salts used were the carbonate, citrate, and tartrate, variously combined with ferratin and quinine.

Why does Cerebral Syphilis Seem Difficult to Cure?—O. Ziemssen says that, like any other syphilitic manifestation, cerebral lues requires the most thorough and energetic treatment, even when apparently only slight in intensity. One of the reasons why many cases are refractory is that the older belief that the use of mercury is conducive to nerve lesion still persists and renders the physician timid in his use of the metal, while the author believes that such fear is wholly unfounded. The difficulty of early diagnosis, and the fact that the effects of the treatment are slow to appear, and the therapeutic test often does not react positively, because too soon abandoned, are further reasons for bad success in managing these cases. The chief requisites are vigorous and prolonged mercurial inunctions combined with iodide. Inunctions are to be preferred because they permit maximal dosage without danger to life, and the treatment must be continued till all symptoms, both subjective and objective, have completely disappeared.

Conclusions Based upon Three Hundred and Thirty Outbreaks of Infectious Diseases Spread through the Milk-Supply.—George M. Kober states that sour milk, or milk which is on the point of turning, is very liable in infants, children, or persons with feeble digestion to produce gastric and intestinal catarrhs of an acute or chronic character. The sediment, so common in milk, is composed of epithelial débris, hairs of the cow, organic and inorganic dust particles, bacteria, fungi and spores of every description, and excrementitious matter from the cow. Fully ninety per cent. of the bacteria found in such specimens are fecal bacilli, which multiply very rapidly and hasten decomposition of the milk. Some samples of milk which have been analyzed showed a higher number of bacteria than the sewage water of the city. Milk may be rendered unfit for use and cause sickness in children by reason of improper food of the animal or while the animal is being treated with strong remedial agents, which may be excreted in the milk. Milk may be morbific as the product of a diseased animal; tuberculosis, for example, may be transmitted. Milk may acquire infective properties after it leaves the udder of the animal. Numerous instances have been observed in which outbreaks of typhoid fever, scarlet fever, and diphtheria, by their sudden and explosive character, affecting families living in streets and localities supplied by the same milkman, naturally pointed to the milk-supply as a common cause. Bacteriologists have proved that disease germs not only live but often also proliferate in the milk. Infection may be carried by water, through the agency of scrubbing-brushes, dish-cloths, and flies. In the epidemics analyzed the largest number has been recorded by English authors, the next by American. This is probably due to the fact that English and Americans usually drink raw milk, while on the Continent it is nearly always boiled. Since careful inspection has been given to the milk-supply, there was shown in one year a decrease of about fifty per cent. in the deaths from diarrhœal diseases of children, and even then the inspections extended over only one-third of the source of milk-supply.

Laryngeal Hemorrhage from an Apparently Normal Larynx.—George B. Wood believes from his investigations in this subject that active bleeding unaccompanied by destructive disease of the larynx is of very rare occurrence. He reports the following case: Mr. D——, aged thirty-six years, has been a healthy man all his life; somewhat addicted to alcohol, though never excessively so. The writer saw him first on August 10, 1899. He was spitting up a small quantity of bright-red blood every few minutes. There was no cough. His lungs were found to be in perfect condition. The nose was normal, excepting a small septal ridge on the left side, and no blood could be seen by anterior rhinoscopy. The vault of the pharynx, the posterior pharyngeal wall, and the lingual tonsil were flecked with small blood clots. The arytenoid cartilages and the intervening fold of mucous membrane were red and covered with blood which evidently came from the larynx. The vocal cords and anterior wall of the trachea were also covered with blood. The actual bleeding spot could not be determined

Later examination showed a small red point at the anterior end of the left vocal cord, possibly the source of the bleeding. On February 13, 1901, the patient returned with practically the same symptoms. This time a thin streak of blood was seen running down the anterior wall of the trachea. The consultant believed that the hemorrhage came from the larynx, and almost surely from a spot just below the anterior commissure. There was marked dilatation of all the veins of the gums, pharynx, and larynx. Suprarenal extract, locally applied, stopped the bleeding for three or four hours, when it returned again in very slight quantity. In the general examination only one abnormality was discovered—a marked oxaluria. It seems hard to believe that the dilatation of the veins was due to the condition of the oxaluria, though the coincident decrease in the size of the vessels following decrease in the amount of oxalates in the urine was somewhat suggestive. The author, in reviewing this case, can see no assignable cause for the hemorrhage which seems to him conclusive.

Blastomycetic Dermatitis of the Gluteal Region.—Frederick G. Harris reports this case. The patient, a woman of seventy-eight years, nearly four years ago noticed a pimple on her left hip, which became a roughened area of intense itching, and later, on account of scratching, became apparently denuded of epithelium. The growth gradually increased in size and the itching persisted, but with a lessened intensity. She was admitted to the hospital as a case of syphilitic ulcer; later a diagnosis of epithelioma was made from microscopical examination. The patient complained only of itching; there had been no actual pain. The neighboring glands were but slightly enlarged. In the core of the growth, so to speak, were irregular masses of epithelium, many of which were hollow, and contained corium infiltrated with round and plasma cells and leucocytes. Here and there in these islands of epithelium were miliary abscesses so characteristic of this disease. These were composed mostly of multinuclear leucocytes, desquamated epithelial cells, more or less granular material, an occasional giant cell, and the specific organism. The abscesses were most numerous deep in the corium, where the organisms and giant cells were also more common. Once in a while a giant cell was seen containing the blastomycetic organism. This organism was the typical double-contoured circular or oval body having a mass of deeply staining, granular protoplasm, usually eccentrically placed, and often containing one or more vacuoles. The organisms varied much in size, and were found in groups of two or more. The appendages of the skin, hair follicles, and glands had entirely disappeared. The treatment was complete excision of the affected area and the sliding of cutaneous flaps to cover the defect. There is no evidence of recurrence.

Subinvolution of the Uterus: Three Suggestive Cases.—L. W. Atlee describes his treatment in cases of this nature: First, to produce daily evacuation of the bowels a drachm of sulphate of magnesium is given half an hour before breakfast. It has a better mental effect when given in a solution with aqua menthæ piperitæ, one drachm to half an ounce, to be taken in a half-glassful of water. A one-grain Bonjean's ergotin pill is to be taken an hour after meals. The only topical application in this case described was one gallon of water at 110° F. twice a day, in the dorsal position, with the hips well elevated. Plenty of good, wholesome food should be taken, and the patient should remain in bed as long as it is painful to stand erect. The most common causes for subinvolution are too early rising after childbirth or miscarriage, lacerations of the cervix or perineum, and septic infection resulting in the various inflammations of the pelvic contents, also the displacements of the uterus due to the laxity of the supporting structures from the same condition of subinvolution in them. Again, concerning treatment: iron and tonics are invaluable; plenty of fresh air; three glasses of warm, fresh milk every day, one hour before meals, is a great help; the warm salt bath is beneficial; ergot is most valuable; the application of the proper electric current is of use, but it is expensive. The heavy uterus should be sustained by a soft-rubber ring pessary. All heavy skirts should hang from the shoulders.

The Protozoon of Cancer.—By Harvey R. Gaylord.

The Physician and Surgeon, April, 1901.

The Management of Trachoma.—Charles H. Baker points out that, as the disease is of germ origin, antiseptic treatment is required. In the acute stage pain and smarting can be relieved by the use of a two- to four-per-cent. collyrium of cocaine and boric acid, being careful to use crystallized cocaine hydrochlorate. The patient may also apply to the lids a saturated solution of boric acid—either very hot or very cold. Once daily the surgeon should evert the lids and apply to the conjunctiva, with considerable friction, a solution of chloride of mercury, 1:1,000 or 1:600. If granules form, they must be emptied. The author finds Knapp's roller forceps the best for this purpose, and describes the process, which usually bring about a cure in two or three weeks.

The Etiology and Rational Treatment of Disease.—George B. McCallum gives all credit to the scientists who are investigating the etiology of disease with the view of discovering the remedy. Meanwhile, he says, we must not forget that a reduced system is essential to the development of disease. The causes of deterioration are often overlooked: overeating, improperly cooked food, the lack of sufficient liquid in the system, lack of bathing and exercise, the wearing of heavy, stiff, impervious fabrics, improperly fitted, worry, etc., all tend to reduce vitality and prepare a suitable lodging-place for the germs of disease. Drugs are of use, but far more are used than are necessary.

The Non-Surgical Treatment of Diseases of the Middle Ear.—Eugene V. Riker says that if the Eustachian tube is involved in the inflammation, causing a closure of the tube, inflation should be performed, and should be gradual as to force. For the relief of pain the patient should be put to bed and given a saline cathartic, and dry heat should be applied and a dose of some of the coal-tar products given. Moist heat, oils, and aqueous solutions should be avoided. Opium should not be used, as it might mask symptoms of purulent inflammation with possible mastoid involvement. If relief does not come speedily from these simple measures, paracentesis should be performed.

The Value of the Widal Reaction in Infancy and Childhood.—John Lovett Morse believes that in children the Widal reaction occurs under the same conditions and with the same limitations as in adults. There is some evidence to show that it appears earlier, is feebler, and persists for a shorter time. It is of especial value in two ways in the diagnosis of typhoid in children, first in ruling out many cases of gastro-intestinal disorders which might otherwise be mistaken for typhoid, and second, in making a positive diagnosis possible in many mild cases which might otherwise pass unrecognized. In early infancy the agglutinating power may be transmitted from mother to infant through the milk, not only during the course of typhoid, but also during convalescence and after recovery. It is therefore of somewhat less diagnostic value than in older children and adults. The Widal test promises to be of great value in the determination of the frequency, symptomatology, and pathology of infantile typhoid, concerning all of which much difference of opinion still exists.

Experience in an Epidemic of Typhoid Fever; Fœtal and Infantile Typhoid, Scarlatina Complicating Typhoid, and Vice Versa.—J. Finley Bell, in making a blood test in typhoid, found an enormous leucocytosis for which it was impossible to account by the physical signs or the symptoms present. An examination of unfiltered water, used in making the solution, showed that it contained granular cells with rather distinct nuclei, closely resembling leucocytes. This seems a very possible source of error in the use of the solution in clinical work. The author also reports several cases of typhoid in one family. The mother, who was eight months pregnant, had the disease. An apparently healthy child was born and at once developed a temperature which registered 103.4° the day after birth. A positive Widal reaction was obtained. Three other children in the family had typhoid and scarlatina conjointly.

A Case of Streptococcal Infection Successfully Treated by Antistreptococcus Serum.—J. S. Fowler reports the case of a child suffering from streptococcal stomatitis which led to a general infection. Double pneumonia supervened, and the child's chance of life seemed very poor. Antistreptococcus serum was injected in doses of 5 c.c., night and morning, for several days, with striking results as to temperature, local and general conditions. A second attack of pneumonia occurred a little later, but was of a milder type and was also overcome by serum treatment. The author has never seen any ill consequences from the

use of antistreptococcus serum. Some collapse may occur an hour or two after the first injections, and it is well to give stimulants in anticipation.

OUR LONDON LETTER.

(From Our Special Correspondent.)

ARMY MEDICAL REORGANIZATION—GYNÆCOLOGICAL SOCIETY ON RETROVERSION—ROYAL SOCIETY—HONORS FOR SIR F. TREVES AND MR. FRIPP—OUTBREAKS OF SCARLET FEVER AND TYPHOID.

LONDON, May 10, 1901.

NATURALLY our attention is very much occupied by the war and the proposed reorganization of the army, which is now before Parliament. With regard to the medical service the minister of war has promised to make it effective, but there are as yet no indications that he will be able to accomplish so desirable a reform. The intense jealousy of the military is a curious phenomenon when you consider that every soldier is liable to become dependent on the doctor for help. In civil life the officers who treat the army surgeons so badly know how to behave to the advisers they call in. And yet even on active service they too often exhibit an assumption of superiority which their manners and education combined show they are far from possessing. But let these thoughts pass. We are considering day by day the manner of improving the service, and every one seems to have some suggestion or other. Accordingly, the council of the British Medical Association has adopted a report of a committee of experienced officers, and *The Lancet*, after a series of articles analyzing the report of the royal commission, has formulated its suggestions for reorganization of the service. The former report is issued in a supplement to the journal, filling eight pages, and is entitled "provisional." It may not be too long for some, but others will regret that the council again buries its proposals in so much verbiage. Attention is once more called to the fact that the medical service is two hundred below what it was forty years ago. That is one proof of the way this service has been starved and even strangled. But the militia once had three hundred surgeons attached. These have been got rid of, so that the combined service is five hundred short of the old number.

It has not been without warnings that successive governments have thus determined to run the utmost risks, trusting if war did break out the profession would rush to the rescue. But with the best intentions the civilian profession can only supplement, not take the place of a trained service. Thirteen years ago a reserve was arranged for. It was only a paper reserve and served only to throw dust in the eyes of the nation. The War Office has not dared to call up this reserve, knowing right well what a revelation doing so would be to the public. It is just as great a sham as the vaunted competition, and I have several times told you that there have been more vacancies than candidates at the "competitive examinations." It is now proposed to abolish this method of entering the service. Both the reports recommend this, but they differ somewhat as to providing a substitute. There is in some quarters a sort of tenderness toward the examination system and a fear of nomination pure and simple. Some sort of compromise is accordingly sought. It will require all the energy of the war minister to carry out his own proposals for the army, and we may fear he will have but little left to free the medical service from the trammels of the War Office and its red tape.

Among its other recommendations *The Lancet* would have the Army Medical School removed from Netley to London. That is a bold proposal. It would perhaps have certain advantages, but there are very great difficulties in such a removal and some obvious objections. Still it may be worth considering at a time when not only the medical department, but every branch of our military service, is being subjected to keen criticism with a view to its complete reorganization.

A discussion has been held at the Gynæcological Society on retroversion of the uterus. It was introduced by Dr. Macnaughton-Jones in an elaborate paper touching on the etiology, clinical and pathological consequences, the preventive, palliative, and radical treatment of backward displacements generally. At the outset he referred to the character of the society, which numbers among its fellows a goodly number of general surgeons who are also eminent gynæcologists. Procidentia he passed by as having been recently dealt with by the late president, Mr. Bowerman Jessett. He therefore devoted himself to retrodeviations, accepting Schultze's definitions, distinguishing between the terms retroposition or deviation and retroversion with flexion. Clinically, backward displacements are naturally divisible into those in which the uterus is movable and reducible, with or without complications, and those in which it is adherent and irreducible and in which adnexal complications, not necessarily but generally, co-exist. A general clinical division of this kind, although it may seem somewhat vague, is of considerable use in reference to the question of surgical intervention. Having considered the cases requiring operation and the methods of proceeding, he added his authority to the numerous gynæcologists who have advocated the Alexander-Adams operation in reducible cases.

Dr. W. Alexander then spoke. He mentioned the clinical results which followed backward displacement. The symptoms are prominent in acute recent cases, and pass by as the disease becomes chronic, to which fact he attributed the statement sometimes made that it gives rise to no symptoms. He said this would be paralleled by a surgeon who said that dislocation of the shoulder produced no symptoms because he found a case of old luxation mobile. Palliative treatment, he admitted, might often relieve all the symptoms, but required much time, care, and skill. These were so often unavailable that operation was necessary. In his own operation, he said, failure would occur if the uterus sloped back ever so little, and this he thought was the cause of many failures. If adhesions were present he opened Douglas' pouch and broke them down with his finger until he could push the uterus forward into anteversion. Then he shortened the round ligaments, having packed the vagina with gauze. If any lesion were found in the pelvis, he removed it by the vaginal opening at the same sitting.

Prof. J. W. Taylor said backward displacement was a dislocation which, when recent, caused great suffering, although when chronic and unaccompanied by enlargement of the uterus it might give rise to no symptoms. It was the recent, or else the intractable, cases with enlarged uterus which called for treatment, and this should deal with both the displacement and the enlargement. He gave his experience of the several operations proposed, and concluded that Alexander's was far the best for uncomplicated cases. When chronic endometritis was present, he began the round-ligament operation by disinfection and curetting.

Dr. Routh believed that many cases would yield to a stem pessary, and be intractable to other treatment without the pessary.

Mr. Jessett also held that many cases could be cured by a proper pessary; also that under an anæsthetic a uterus which had seemed quite fixed could often be easily replaced in the normal position. When operation was necessary, he preferred ventro-fixation.

Dr. Elder spoke of the importance of bad miscarriages and labors as causes. He had given up Alexander's operation in favor of abdominal ventro-fixation.

Professor Sinclair said a stem ought not to be left in more than a fraction of a week. He had done Alexander's operation forty or fifty times, and found it suitable only when no complications were present. But such cases could be cured without operation. In old cases, when operation was needed, the only safe one was ventro-fixation. If a subsequent pregnancy could occur, the fundus must not be involved in the stitches, and the natural play of the round ligaments must not be impaired.

The discussion was then adjourned.

The *conversazione* of the Royal Society took place on Wednesday evening. There were a brilliant gathering and some beautiful exhibits to entertain the assembly. Among these were samples of the dust constituting the "blood-rain" which fell in Sicily and was duly recorded by telegraph in all countries. There was also a collection of specimens of African parasitology exhibited by the Liverpool Tropical School. I hear that the usual second gathering of the society—sometimes called the ladies' night—will be omitted this year on account of Queen Victoria's death.

Major Ronald Ross is recommended by the council for the fellowship. So is Dr. C. J. Martin, of Melbourne University, and Major A. W. Alcock, of the Calcutta Medical College. Knighthood of the Victorian Order has been conferred on Mr. Treves, who had previously received A.C.B. Mr. Fripp is made a C.V.O. and is appointed surgeon in ordinary to the King; the appointment he held to His Majesty when Prince of Wales.

An outbreak of scarlet fever in Bethnal Green and Shoreditch has apparently been traced to infected milk.

From the report of the medical officer of the county council two localized outbreaks of typhoid fever seem to have been caused by fried fish. But this will require further investigation, especially considering that the fish was cooked—if insufficiently.

DR. HILL'S REJOINDER TO DR. DALTON ON "WOUNDS OF THE HEART."

To the Editor of the Medical Record.

Sir: Professor Dalton, of St. Louis, says in a recent issue of the Medical Record: "My attention has been called to an article in your journal of December 15, 1900, by Dr. L. L. Hill, of Montgomery, Ala., on 'Wounds of the Heart.' Dr. Hill had evidently not seen my article in the *Annals of Surgery*, February, 1895, in which I reported, 'A case of stab wound of the pericardium, terminating in recovery after resection of a rib and suture of the pericardium.' My operation was done in September, 1891, while I was in charge of the St. Louis City Hospital." I desire to say that I had read the report of Dr. Dalton's case in the *Annals of Surgery*, had seen it referred to by Dr. Duncan Eve in Park's "Surgery," and by Drs. Keene and Da Costa in the *American Year-Book of Medicine and Surgery*. I wish to remind Dr. Dalton that my paper was upon "Wounds of the Heart" and not upon the "Wounds of the Pericardium." If I had intended reviewing the surgery of the pericardium, I should certainly not have overlooked paracentesis pericardii, first performed by Romero, of Barcelona, in 1819, and would have given a full account of pericardotomy for the removal of foreign bodies by that great Scotchman, John Bell, who died the year following Romero's operation. I would not have ignored the achievements of Dr. John B. Roberts, of Philadelphia. If so high an authority as Professor Giordano, of Naples, is to be credited, Farrina, in 1896, sutured with three silk stitches a wound of the right ventricle 6 mm. in length. Cappelen, in 1896, sutured a wound of the left ventricle four-fifths of an inch in length. These were the first cases of suture of the human heart, though Roberts, of Philadelphia, had suggested it in 1881, and Del Vecchio, of Naples, in 1894, demonstrated its feasibility before the Eleventh International Medical Congress in Rome, by his experiments on dogs. Dr. Dalton says: "Dr. Hill states that the first operation upon the heart was done in 1896, by Farrina and Cappelen. My operation upon the pericardium antedates this by five years." In his original article he says: "Before closing the pericardial wound I inserted my index finger but could not discover that the knife penetrated the heart." These are separate and distinct surgical procedures, and I fail to see how Professor Dalton's claim of being the first to suture the pericardium in 1891 disproves my statement that Farrina and Cappelen were the first to suture the heart in 1896, or in any way vitiates their claim to priority.

L. L. Hill, M.D.

Montgomery, Ala.

OUR PARIS LETTER.

To the Editor of the Medical Record.

THE TREATMENT OF FLOATING KIDNEY BY MASSAGE — TUFFIER ON SPINAL ANÆSTHESIA—DEATH OF DR. HENRY NAPIAS—ECONOMY IN HOSPITAL MINISTRATION.

Paris, May 14, 1901.

Sir: Dr. Richelot, surgeon of the St. Louis Hospital, has been trying a new treatment in his service for floating kidney. At the meeting held by the Society of Surgery on May 1st, he said that the usual methods of treatment, such as bandages or nephropexy, proved ineffectual in a great number of cases. Floating kidney is often due to a certain degree of congestion, akin to that seen in the uterus when the patient is nervous and arthritic. Massage would naturally have a tendency to decrease the congestion of the kidney and thereby bring it back to its original position. This treatment was tried in several cases and the results were highly satisfactory.

The discussion on the use of intrarachidian injections continues to be as fierce as ever. Dr. Tuffier has sent another article to the *Presse Médicale* of April 24th. He remarks that he has now performed some four hundred operations with this method, and he is therefore able to discuss the question more thoroughly than some eighteen months ago. He admits that Corning's name is inseparably linked to the history of medullary cocainization, but he does not approve the way in which his American colleagues have taken up arms in his behalf. Bier was the first to use this method as a means of producing operative anæsthesia, but Dr. Tuffier says that, if he had been obliged to use the technique indicated by his colleague of Greifswald, he would never have cared to undertake it. Dr. Tuffier went on to describe his method, and said he used a two-per-cent. solution of cocaine. He had tried other preparations, such as a saline solution more or less condensed, tropa-cocaine and others. The results were, however, unsatisfactory. A saline solution does not give any result. As for one-per-cent or 0.50-per-cent. solutions the effect is not lasting enough. Dr. Tuffier remarked that the intrarachidian tension played a rôle of importance, as the anæsthesia was more perfect when it was high. The injection should be made very slowly, at least a minute being taken to inject one gram. Dr. Tuffier has sometimes been able to obtain anæsthesia in the upper two-thirds of the thorax by using 3 cgm. of cocaine and making the injection rapidly. The most important part of Dr. Tuffier's article was his discussion of the danger due to the use of cocaine injections. He said, first of all, that he had not so far been aware of a single nervous accident happening after the use of cocaine, when administered according to the technique he has recommended. Of course, if a surgeon uses a medium-sized trocar, as Bier did, and allows a large quantity of liquid to escape, if he makes the injection rapidly, if he changes the dose, accidents will occur. As for the mortality due to this method, great care should be taken to examine well the statistics furnished and to compare them with those given for chloroform or ether narcosis. The mortality due to chloroform is one in every twenty-five hundred, that of ether one in seven thousand, that is, during the operation. But the deaths taking place afterward should be taken into consideration, and Schultze, in his report on forty-nine hundred and nineteen etherizations, mentions eighteen pneumonias, nine of which proved fatal. As for medullary anæsthesia, there has not been reported so far a single case of death. All the cases of death cited so far are due to complications after the operation. Of the six cases cited by Dr. Reclus, two—those of Jullien and Tuffier—have seemed doubtful even to Dr. Reclus. As for the other four, one—that of Henneborg—was a case of tuberculous meningitis, in which puncture was only a means of making the diagnosis, and not a single drop of cocaine was injected. The second case was that of Dumont. The patient was suffering from acute tuberculosis and died the sixth day after the operation. The autopsy showed general tuberculosis. The third was that of Goilav, of Bucharest. Death took place twenty hours after the operation, but there is no indication of the way in which the injection was made, and no autopsy was carried out. The same uncertainty is to be found in Jonnesco's case, and even more so in that of Keen, which neither Dr. Reclus nor Dr. Tuffier have been able to verify. Dr. Tuffier considers this last case all the more suspicious in that this author, Dr. Keen, makes out that Dr. Tuffier has had six deaths.

Dr. Tuffier ended his article by saying that one could judge what value one should give to the documents presented to the Academy. He did not wish to show himself too ardent a defender of the use of chloroform, though he had lost only one patient by its use, but he considered that Dr. Reclus had been rather premature in pronouncing its funeral oration.

Dr. Henry Napias, the general director of the Assistance Publique, has just died. He had filled this position during the last three years. He was navy surgeon until 1871, when he established himself as physician in Paris and became editor of the *République Française*, Gambetta's newspaper. Later he was named inspector of hygiene, published a book on the subject, and became a member of the Academy of Medicine. One of the causes of the increase of the number of physicians in France is the military law of 1889. By this law medical students are required to do only one year of military service, and a great many young men take up medicine as a profession to escape having to serve three years.

At a recent meeting held under the direction of Mr. Krantz, a deputy, this subject was brought up, and he recommended the striking out of the article allowing any dispensation to physicians.

The general administration of the Paris hospitals has just sent a notice to the physicians of the hospitals notifying them that the increase in expenditure has been so great that it has been found necessary to establish a commission which will study the means of decreasing the expenses by replacing certain drugs by others less expensive, and by diminishing the use of them. A few facts speak rather eloquently as to the increased expenditure:

Codeine is much more used, 45 kgm. being employed whereas twelve years ago only 2 were found needful. The well-known Todd's potion is the cause of great expenditure, as 135,000 francs worth of rum has to be bought; 50,000 francs are spent for camphorated alcohol, and 250,000 for other alcoholic preparations. Certain drugs, such as musk, which costs 4,500 francs per kilogram, and pilocarpine 3,000, will henceforth be given only when the physician-in-chief has made out a special order for the same. It is astonishing how dear some drugs are, crystalline digitalin costing 30,000 francs per kilogram, homatropine 20,000 francs. Ergotinin is the dearest of all, costing 35,000 francs per kilogram.

According to recent statistics, suicide is more frequent among males than females, the proportion being four to one. Carbolic acid is the most used of all the poisons.

Reviews and Notices.

The History of Medicine in the United States, with a Supplementary Chapter on the Discovery of Anæsthesia. By Francis Randolph Packard, M.D. 8vo, pp. 542. Philadelphia and London: J. B. Lippincott Co. 1901.

It is always a pleasure to meet with a new book on a new subject. The present work partakes of both characters in a special degree. The topics discussed are of the greatest interest as showing the evolution of American medicine from the earliest colonial history to the close of the Revolutionary War. The painstaking labors of the author cannot be too highly appreciated by the reader when the great difficulty of collecting the facts of the history is duly considered. While numerous books and essays have been published regarding local medical history of different parts of the United States, no special effort has been made in the direction of a general history of early medicine. The plan of this work is admirable in every respect, and is that of a history of epochs with the leading facts of interest training in due chronological order. The reader is edified at every turn, whether in acquainting himself with the early struggles of the pioneers, or learning of the strange remedies of years ago, the peculiar theories of disease, the prayers against plagues, and the struggles to establish our early hospitals and colleges. From the historical point of view the volume is of peculiar value from the fact that it is unique in design and purpose. Within the limits of a cursory review it is impossible to deal with its contents in detail. It may be enough to say that as a history of medicine it is a model in its way. Not the least interesting part is the chapter on Anæsthesia, which naturally finds its place in every account of American achievement in medicine. Several of the portraits are quite rare, and many of the other illustrations present an equally interesting feature of the work. In those bygone days there were quacks, quarrels, and the usual generous rivalries for social and political preferment that obtain even in this day, making history repeat itself in all the essential particulars that pertain to men and things here and everywhere. One of the many admirable qualities of the book is the pleasant narrative style of the author. Altogether it is a work which does credit to the literature of medicine and must find its place upon the shelf of every well-appointed medical library.

The Feeding of Infants: Home Guide for Modifying Milk. By Joseph E. Winters, M.D., Professor of Diseases of Children, Cornell University Medical College. 12mo. New York: E. P. Dutton & Co. 1901.

This handy little volume, though intended by the author for the instruction of mothers and nurses in the modification of milk for infant feeding, will be found a very excellent guide for the general practitioner. Although it is a book of less than fifty pages, the reader obtains a clearer practical knowledge of infant feeding than is to be had from many of the more voluminous works on the subject. It is not always an easy task to nourish an infant properly, and occasionally the physician finds that his best efforts in that direction have been rewarded by nothing more brilliant than a case of rachitis. It has been well said that one baby's food may be another baby's poison. We believe, however, that with an intelligent use of the formulæ given by the author, which are based upon an extensive experience, for modifying milk for different periods, from birth to the twelfth month, it must be an exceptional case that cannot be successfully managed. Attention is directed to the very important fact that fresh raw milk is superior in nutritive value to that which has been changed by pasteurization, and that when proper cleanliness is observed in the production and handling of milk pasteurization is unnecessary. The author concludes with a terse and logical discussion of so-called "Infant Foods," in which he expresses the belief that our knowledge of the composition of human milk and our ability correctly to modify cow's milk as a substitute for it will eventually eliminate preserved foods forever from the nursery.

The Technique of Surgical Gynæcology: Devoted Exclusively to a Description of the Technique of Gynæcological Operations. By Augustin H. Goelet, M.D., Professor of Gynæcology in the New York School of Clinical Medicine. 12mo. New York: International Journal of Surgery Co.

If there be justification in the publication of another work on gynæcology, we feel that the author of this book has no reason to make an apology for increasing the number of already published books on this subject. The object of the book, as he states, is "devoted exclusively to operative technique, preparation for operations, and after-care of the patient, giving no space to diagnosis or to a discussion of the necessity for operation." We can only praise this volume in the highest terms, not alone that the specific object in writing is attained but because the explicitness of plain sense is evidenced in every line and page. There is no waste of words, there are no pros and cons to confuse the reader. The whole volume is replete with good, safe teaching. Everything is to the point, every statement is compact. The plates are exceptionally good, plainly suggestive, and are taken from life. The author attempts to give, as he states, but one method of procedure described for each condition—one which he has found most satisfactory in its execution and most successful in its results. This one feature mars to some extent the otherwise great value of the book, especially so in the chapter on Appendicitis. Here mention is made only of the direct cutting operation—absolutely no mention of the most valuable of all, the muscle-splitting methods, which every one must know are of inestimable value. Except for this, which can be easily remedied in a new edition, we praise the work in its entirety with unstinted enthusiasm and feel well assured that the book will have the large sale it well deserves.

Oral Sepsis as a Cause of "Septic Gastritis," "Toxic Gastritis," and Other Septic Conditions. By William Hunter, M.D., F.R.C.P., etc. London, Paris, New York, and Melbourne: Cassell & Co., Ltd. 1901.

This is a reprint of an article in *The Practitioner* in which the author wishes to call attention to the serious consequences of septic conditions in the mouth. He adds a number of illustrative cases.

Surgical Affections of the Trunk, the Mammæ, and the Genital Organs of the Female; Statistics and Observations. By Dr. Polaillon, Honorary Surgeon to the Hôtel Dieu, Professor of Medicine in Paris, Member of the Academy of Medicine. 8vo, pp. 874. Illustrated. Paris: Octave Doin. 1901.

In the work before us we have one part of a series of compilations by the same author. The entire work appears to be in two large volumes, of which the book before us is the end of the present series. It makes a valuable addition to the already overstocked market of gynæcological works. But yet it must remain unique in its particular field, since it introduces a radical departure from what we are accustomed to expect in volumes written on the diseases peculiar to women. Any writer with the enormous experience of Professor Polaillon in his many years of constant close observation must of necessity be able to give to his colleagues much of the greatest value when he writes a large work such as the one before us, basing his remarks on the data derived from personal observations in his own practice. His own statistical evidence and observation are consequently the keynote of this extremely valuable book. Naturally, therefore, one expects to find matter of great practical value, and, what is of greater importance, every line is clean lean meat and remarkably well stated, without the least bit of the "ego" one would naturally expect in a book written and formed on the lines. This work, which is but the first part of the second volume, consists of seven hundred and forty-eight pages of closely printed lines. It treats in the beginning of affections of the female breast. The second subdivision treats, in a systematic fashion, of the various gynæcological lesions, which are most thoroughly discussed and dilated upon by an array of carefully selected histories illustrating the diseases under discussion. In this way to the reader is imparted much useful knowledge which it is impossible to give in any other way. In short, as a thoroughly practical treatise it is one that can be read with profit by the general practitioner, and for such, and such only, can it be recommended. As a guide for the student, while it may make pleasant reading for leisure moments, it appears to us to be entirely too practical and to yield too little theoretical knowledge to be of much value.

Relative Value of Anæsthetics.—The danger rate begins to increase after the thirtieth year under chloroform, but with ether it remains constant until after the fiftieth year. Apparently none of the mixtures of ether or chloroform gives such satisfactory results as ether alone. Nitrous oxide with or without oxygen shows the lowest percentage of complications. The final conclusion of the anæsthetic committee of the British Medical Association is that the most important factor is the skill of the anæsthetist, and that to insure the best results he must be one of large experience and good judgment.—*Ed. Albany Medical Annals*, April.

Society Reports.

THE PRACTITIONERS' SOCIETY.

One Hundred and Sixty-third Regular Meeting, Held on Friday, April 5, 1901.

JOSEPH D. BRYANT, M.D., PRESIDENT PRO TEM.

Sarcoma of the Inferior Maxilla, Twenty Years after Partial Resection.—DR. WILLIAM T. BULL presented the patient, a woman thirty-eight years old, upon whom he had performed a partial excision of the lower jaw for giant-celled sarcoma in June, 1880, now nearly twenty-one years ago. At that time the growth had been in existence about one year. It involved the floor of the mouth and part of the jaw corresponding to the incisor and canine teeth of both sides, and presented the characteristic features of a central sarcoma about the size of an egg. It was removed, together with a margin of healthy bone on each side, and the patient made an uneventful recovery. The microscope showed the growth to be a giant-celled sarcoma. Since the operation she had enjoyed perfect health. There had been considerable atrophy of the muscles of the lower jaw, of which only the part carrying the molar teeth was left behind. The chin had fallen in slightly. Dentists had been unable to fit her with a satisfactory artificial plate. There was no impairment of speech, and she was able to masticate her food fairly well with the assistance of her tongue.

DR. JOSEPH D. BRYANT said it was important that cases like this should go on record, as they would serve to influence those who were similarly afflicted to submit to early operation. The speaker asked Dr. Bull whether there was any exciting cause in connection with the case.

DR. BULL replied that none could be elicited. There was no history of cancer in the family.

A Case of Fracture of Both Bones of the Forearm, with Skiagraphs.—Dr. Bull presented a man fifty years of age, who, about two years ago, had fallen from his bicycle, sustaining a fracture of the left radius and ulna, the bones being broken about an inch and a half above their lower extremity. An *x*-ray picture, taken at the time of the accident, showed considerable overlapping of the fragments of the radius and angular displacement of those of the ulna. The displaced fragments were adjusted as well as possible, and appropriate pads applied. A second *x*-ray was then taken, which showed that the displacement was not affected by the efforts at reduction. Without any further attempts the arm was put up in lateral splints with pads. Firm union resulted after five weeks, and three months later it was found that the cosmetic and functional results were entirely satisfactory. In connection with this case, Dr. Bull exhibited a number of skiagraphs, taken before and after the treatment, which showed that there was still marked displacement of the fragments, in spite of the excellent functional result. This fact had long been known to surgeons, but to patients the study of such skiagraphs was apt to give rise to much worry and discomfiture.

DR. BEVERLEY ROBINSON said the case reported by Dr. Bull, and the skiagraphs shown in connection therewith, were important in view of the fact that the treatment of fractured bones was so commonly the cause of malpractice suits. Dr. Bull's case showed that a good functional result might be obtained without perfect approximation of the fragments, and that it was not always possible to obtain the latter.

DR. BRYANT said that several weeks ago he was called to see a case of injury about the elbow-joint. The parts were so much swollen that it was impossible to make out the exact condition of affairs. An *x*-ray picture was taken, which disclosed fracture of the lower end of the humerus; it also showed that the upper end of the lower fragment was overriding its fellow. This displacement persisted after the condition had been treated by the attending surgeon, a very competent man, and the inspection of the skiagraph disturbed the patient and his friends to such a degree that they decided to transfer their allegiance to another surgeon. Dr. Bryant said he had no doubt that this patient would have made a perfectly satisfactory recovery under the care of the original surgeon, and the deformity would not have been suspected but for the *x*-ray picture. In another case which came under the speaker's observation there was a fracture of the lower end of the femur with about a quarter of an inch shortening, which the *x*-ray showed to be due to an overriding of the upper fragment. This overriding was demonstrated by repeated examination with the *x*-ray, could not be overcome in spite of every effort, and the patient recovered with an entirely satisfactory limb.

Varicose Veins of the Abdomen and Extremities.—DR. EDWARD G. JANEWAY showed a physician, fifty years old, with numerous varicose veins coursing over the surface of the abdomen and lower extremities. The varicosities on the latter had existed for thirty-two years, while those in the abdominal region had been first noticed about ten years later. They were tortuous and very prominent, and it was readily demonstrated that their current of blood flowed upward. Dr. Janeway said the patient gave no history of syphilis, and cirrhosis of the liver could be excluded. The right lobe of the liver was considerably smaller than usual, while the left lobe was somewhat enlarged. There was no enlargement of the spleen. The only explanation he could offer for this rather unique condition was that there was some obstruction to the passage of the blood through the vena cava. This vein travelled through a groove in the under surface of the liver, and in some way its lumen might have become narrowed and its current of blood diverted. The man suffered no inconvenience from his varicose veins, and he had not consulted Dr. Janeway because of them, but for a slight albuminuria.

DR. ROBINSON said that such a condition must be extremely rare, and he asked whether Dr. Janeway had ever been able to verify it at autopsy.

DR. JANEWAY replied that in advanced cirrhosis he had seen the vena cava constricted, but in this case the cardinal symptoms of cirrhosis of the liver were absent. The spleen was not enlarged and the man never had ascites. In addition to this patient's albuminuria, he complained of being very weak, which weakness might be due to an impairment of the function of the liver.

DR. ROBINSON, in speaking of the treatment of varicose veins in the extremities, mentioned the fact that Dr. Musser, of Philadelphia, had suggested the internal use of hamamelis in large doses.

Systolic Murmur in the Second Left Interspace, with Thrill.—DR. JANEWAY presented a man of twenty who was under his care for albuminuria. The interesting feature in connection with the case was the presence of a systolic murmur in the second left interspace; it was heard only upon forced expiration and was accompanied by a distinct thrill. Dr. Janeway said that several months ago Dr. Brannan had presented a patient with a murmur in this situation (but without a thrill), which he had felt inclined to attribute to mitral insufficiency, without the existence of a murmur below. Dr. Janeway said he was rather inclined to the opinion that the murmur and thrill in his case were the result of compression of the pulmonary artery by the forced expiration.

DR. ROBINSON suggested that the thrill might be ex-

plained by the presence of adhesions at the apex, which were put upon a stretch during expiration.

Dr. Janeway said he thought the bruit came not from the apex, but from the pulmonary artery.

Two Cases of Fracture of the Patella Treated by the Conservative Method.—Dr. William T. Bull said that the question of the best method to pursue in the treatment of a fractured patella was still the subject of considerable discussion among surgeons and one of doubt in the mind of the general practitioner. Not very long ago, when the present King of England sustained a fracture of the patella, the attending surgeon did not suture the fragments, and on that account he was criticised by one of his French colleagues. Both the patients shown by Dr. Bull were physicians, and in both cases the fractured patella had been treated by conservative methods. In one of these patients, thirty years old, the fracture had occurred eleven years ago, as a result of muscular action. There was an interval of about an inch between the fragments. The knee was put up in plaster of Paris, and the patient was up and about in two months. Movement was much impaired at first, but the functional result gradually improved and was perfect at the end of a year. There was ligamentous union. When the splints were removed the fragments were separated about a quarter of an inch; at present the separation was about half an inch. The second patient was twenty-eight years old; the fracture resulted from a fall on the knee while he was crossing the ocean in 1893. The effusion was so great that retentive strips of plaster could not be applied till the end of three weeks. Union apparently bony in character occurred. An *x*-ray after six years detected no ligamentous structures between the fragments. The motions of the joint were regained slowly, but at the end of one year the limb was strong and the movements were perfect.

Dr. Andrew H. Smith said that about fifteen years ago he had seen a case of fracture of the patella in which the conservative treatment was employed with excellent results. The fragments were kept in apposition by means of a bandage. Union was slow, but, in spite of the fact that there was a separation of about an inch and a half at the time of the accident, union was apparently perfect. At the present time the patient was scarcely able to find the line of fracture.

Dr. V. P. Gibney said that in former years one of the favorite methods of treating a fractured patella was by means of an apparatus known as a knee-cap or bandage. This consisted, essentially, of a piece of canvas, which was laced over the joint, with a strip of cork above and below. While this apparatus was not very efficacious and was out of order about half the time, yet the functional results obtained with it were in many instances very good. The speaker said he recalled one case in which both patellæ were fractured at the same time and treated in this way. In spite of the wide separation of the fragments at the time of the accident, which occurred eight or ten years ago, there was scarcely any disability at the present time. Even in cases in which there was considerable separation, the function of the joint was often fully restored. The method of bringing the fragments together by means of strips of adhesive plaster, to which Dr. Bull had referred, often gave excellent results.

Dr. Joseph D. Bryant said he did not think a fractured patella should be wired in every instance, nor was it generally practised. It should not be thus treated unless there was some special indication for doing so. The speaker said that out of twenty-two cases in which he resorted to this procedure, two resulted badly. One of the patients died from delirium tremens, from which he might not have suffered had he not been subjected to the influences incident to wiring the patella—a fact not justly chargeable against the operation. The second case was that of a young woman, who, after the operation, and apparently in spite of every precaution, developed a peri-arthritis followed by limited intra-articular involvement and a stiffened joint, from which the patient suffered to-day.

Dr. P. F. Francke said he had sustained a fracture of his patella eight years ago. It was treated by the conservative method with excellent results. The speaker said he suffered no discomfort from the fracture, excepting that he was at times a little timid in using the limb, fearing a refracture. There was slight atrophy of the quadratus muscle on the affected side, probably the result of his habit of favoring it.

Dr. Le Roy Braun, whose patella had been fractured in 1890 and treated conservatively, said that for the first year or two after the injury he had suffered from occasional attacks of rheumatic pain in the affected knee, which were more pronounced during certain changes of weather. During the past eight years, however, he had suffered no inconvenience whatever from the old injury. He considered one leg as strong as the other, and was able to take long bicycle rides without suffering any discomfort.

A Case of Typhoid Fever in which an Operation was Done for Supposed Appendicitis.—Dr. William T. Bull reported this case. The patient was a married woman, twenty-two years old, whose previous history was unimportant with the exception of two attacks of right-sided abdominal pain, without nausea, occurring in August, 1900. These attacks were three weeks apart and of one or two days' duration. On November 24, 1900, she returned home late at night from a football game at New Haven. She was much fatigued, felt chilly, did not rest well during the night, and complained of moderate generalized abdominal pain. On the following morning she was seen by Dr. S. W. Lambert, who found that her pulse was normal; her temperature, 100° F. The patient complained of pain in the right iliac fossa. Later in the day the pulse rose to 98; the temperature to 101.5°. Some tenderness in the right iliac region and a small indurated area could be made out. There was no muscular rigidity. On this day Dr. Bull saw the case in consultation. On the following morning, November 26th, the pulse was 100; temperature, 100.5°; in the afternoon the pulse was 110; temperature, 103°. Menstruation began without pain. The pain in the right iliac fossa persisted, with headache and backache. The bowels moved upon the administration of an enema. A vaginal and rectal examination proved negative; there were no pulmonary symptoms. On the following day there was muscular rigidity of the right rectus muscle, and a tender indurated area, about the size of the thumb, could be made out in the right iliac fossa. The morning temperature on this date was 101°; pulse, 110; in the afternoon the temperature was 101.8°; pulse, 116. There was slight nausea. After another consultation with Dr. Bull, it was decided, on account of the rising pulse rate and temperature, that the case was one of appendicitis. The muscular rigidity, preceded by localized pain, induration, and tenderness, in addition to the fact that the patient had had two previous attacks of abdominal pain, favored the diagnosis of appendicitis; while in favor of typhoid fever were the facts that there had been no decided drop in the temperature and that the headache and backache were marked. Dr. Bull operated at 10:30 P.M. on November 27th. At that hour the temperature was 103°; pulse, 120. A three-and-one-half-inch incision through the outer border of the right rectus disclosed a distinct, hard induration immediately underneath. When the peritoneum was opened no fluid escaped. About an inch and a half above the junction of the ileum with the cæcum there was a marked swelling in the inner wall of the latter portion

of the gut at its mesenteric junction, due to the presence of an indurated mass about the size of a walnut. It was first supposed to be the appendix, covered with adhesions; the appendix, however, was found below, apparently normal in appearance. It was removed and the stump buried. The cæcum was then opened by an incision through its outer wall; the indurated mass referred to was situated beneath the serosa of the bowel. On its mucous surface was a small ulcer with sharp, punched-out edges and a yellow, sloughy base. The bowel incision was thereupon closed with silk Lembert sutures, and after packing of the wound with gauze down to the involved area in the cæcum, the abdominal incision was partly closed. No enlarged glands were seen, and the ileum for a length of two feet was normal in appearance. The immediate results of the operation were negative. The temperature continued to rise, gradually going up to 105° and 106° four days after operation. Dr. Janeway saw the patient about this time, but did not venture a positive diagnosis. On the ninth day of her illness a Widal test by Dr. Lambert established the diagnosis of typhoid fever. No leucocyte count had been made. The typhoid fever pursued a very severe course, and during the fourth week it was complicated by a double pneumonia and pleurisy on the right side. On December 9th and 10th she had a severe intestinal hemorrhage, lasting twenty-four hours. From December 30th to January 10th the temperature ranged below 101°, but was irregular. From January 10th to January 23d the patient had a relapse, and since then she had made a slow recovery. The duration of her illness was about three months, and during that time her life was despaired of on several occasions. Dr. Bull said that the abdominal wound in this case presented no unusual features, and had apparently no influence on the course of the fever. There was very little discharge, and it healed slowly at the expiration of six weeks.

Dr. George L. Peabody said he had seen two cases of typhoid fever which had been mistaken for appendicitis and operated on. Both patients recovered. On account of the presence of the abdominal wound the hydrotherapeutics of the cases were materially interfered with, and on this account one of them ran a more severe course than it otherwise would have done.

Dr. Janeway said that in obsure cases of this character leucocytosis alone could not be absolutely relied upon. It should be safeguarded by other symptoms. Osler had shown that leucocytosis—at least one above the ordinary—might be found in typhoid fever. This might be the result of some idiosyncrasy. He had had recently a case in which no inflammation could be found, with a count of 13,000 leucocytes on the first examination and a negative Widal. A few days later the Widal was positive; leucocyte count 8,000. Again care must be taken as regarded the Widal reaction, more particularly that no mistake happened in the laboratory by mixing up blood specimens to be examined. This was the only way by which he could account for the result obtained by one examiner in a case seen in consultation a year ago.

Dr. W. Gilman Thompson said that one was liable to be misled by a single leucocyte count in typhoid fever. He had several times seen the number of leucocytes exceed 13,000 in typhoid fever without complications. Thayer had shown that cold sponge baths might exceptionally increase the leucocytosis beyond 20,000. Dr. Thompson said the case of typhoid fever reported by Dr. Bull recalled the descriptions of this disease in the text-books of thirty or forty years ago, when great stress was laid upon pain and gurgling in the right iliac fossa, symptoms which were now regarded as possessing little or no diagnostic value. In typhoid fever there might be some general abdominal pain, but this was as often on one side as on the other.

Dr. Kinnicutt said it was interesting, in connection with the case of typhoid fever reported by Dr. Bull, that a lesion should have developed in the cæcum as early as the third day. This was certainly unusual. The speaker said he had seen the patient several times with Dr. Lambert in consultation during a relapse of the fever, and had noted the fact that she was of a distinctly neurotic temperament. This, perhaps, would account for some of her subjective symptoms. Some of the abdominal pain of which she complained might also have been subjective in character.

Dr. Robinson, in connection with the remarks made by Dr. Thompson, said that the description of the symptoms of typhoid fever in many of our early text-books was taken from the French writers, and was probably in accord with their observations. The profound adynamia which was so commonly observed in typhoid fever in France was very rarely seen here, probably because the infection in this country was less severe.

Dr. Peabody said it must be conceded that our knowledge of leucocytosis and its significance was still quite limited. We knew, for example, that if blood was taken from a warm finger it would show a considerable proportion of leucocytosis, which it would not show when the blood was taken from the same finger if cold. There were a number of exceptional circumstances which might interfere with the reliability of the leucocyte count. However, if repeated examinations showed marked leucocytosis, the fact would militate strongly against the presence of typhoid fever.

Dr. Kinnicutt said that at the present time the consensus of opinion was that leucocytosis was not present in typhoid fever unless it was the result of some complication or congenital peculiarity. At the Presbyterian Hospital during the past winter every typhoid-fever case was subjected to a blood-count every other day, and the results corroborated this opinion.

A Case of Cerebral Sinus Thrombosis.—Dr. F. P. Kinnicutt read a paper with this title. Cases of sinus thrombosis, he stated, might be arranged under two groups: (1) Cases in which the thrombotic process originated outside the intracranial circulation and extended either by the prolongation of the thrombus per contiguitatem or by the propagation of a phlebitis. Such instances were comparatively common and embraced various extracranial lesions, such as disease of the petrous portion of the temporal bone, caries of the cranial bones from any cause, inflammations of the scalp, lesions of the face, etc. (2) Cases of so-called primary thrombosis, known as marantic or autochthonous thrombosis of the cerebral sinuses. These thromboses had long been recognized as occurring in infants suffering from marasmus, also in adults in the last stages of exhausting disease. A subdivision of this group was suggested by Dr. A. Brayton Ball, in an exhaustive paper on the subject, published in 1889. It comprised cases of sinus thrombosis occurring in anæmic adults, especially chlorotic girls, although they were often enjoying fair health. The symptoms of sinus thrombosis were admittedly obscure, as a rule, and in the group of cases described by Dr. Ball the diagnosis was seldom made. Such symptoms as were present were evidently secondary and due to the extension of the thrombus of the sinus or sinuses into the cerebral veins, resulting in localized destruction of the cerebral tissues by hemorrhage, softening, and in subarachnoid and ventricular effusions. Experimental investigations on animals and pathological findings in the human subject indicated that extensive thrombosis of the sinuses might occur without symptoms and with the maintenance of a satisfactory cerebral circulation,

provided the veins proper were not implicated. The case which Dr. Kinnicutt presented might properly be regarded as one of primary thrombosis of the straight sinus with an implication of the venæ Galeni, causing hemorrhage into and softening of the contiguous tissues. The previous history of the case had been kindly furnished to the author by Dr. Emmett Holt, under whose observation the patient had been. Ten days previous to admission to the hospital the patient had a sudden attack of vomiting. The vomiting was repeated several times at short intervals. The temperature was normal, and physical examination of the various organs gave only negative results. Two days later the patient was up and at work, apparently in her usual health, and her symptoms were believed to be due to an acute attack of indigestion. Five days later she suffered from a very similar attack; there were vomiting, a little headache, and some general indisposition without fever. The following day the vomiting had ceased. The pulse was slow but not irregular. The patient seemed dull and answered questions in a vague way. A few hours later she became very restless, could not be kept in bed, talked incoherently, and it was thought desirable to take her to the hospital. She was admitted to Dr. Kinnicutt's wards at the Presbyterian Hospital on the evening of the same day. The record of the examination on admission was: "Female, aged eighteen years, well nourished, somewhat anæmic. She lies in a semi-stupid condition; is either unable or unwilling to answer questions, but evidently understands. There are no pupillary symptoms, no paralysis, no muscular rigidity. The reflexes are normal. Examination of the various organs gives only negative signs. Pulse, 120, but of good quality; respiration, 36; temperature, 101°." The patient grew rapidly worse after admission. The coma became more marked and she could not be roused. There were irregular convulsive movements of the hands and legs at intervals, and finally, ten hours after admission, there were two severe general convulsions within a short interval, in the latter of which the patient died. Shortly before death the temperature rose to 103.8° and the pulse to 180. The autopsy was made ten hours after death. Anatomical diagnosis: Thrombosis of cerebral sinuses (straight sinus, left lateral sinus, and venæ Galeni); hemorrhagic softening of the left optic thalamus. In the brain there were thrombi, evidently formed before death, in the veins of Galen, in the straight sinus, and in the upper part of the left lateral sinus. The other sinuses were normal. The dura and pia mater were normal, though there was a little opaqueness of the latter over some areas. An area of hemorrhagic softening included the entire left optic thalamus; the neighboring walls of the lateral and third ventricles showed distinct superficial softening. The brain otherwise was normal. Section of the veins of Galen showed that they contained blood clot. There was a great abundance of pigment granules, and many large clusters of polymorphonuclear leucocytes, especially in the peripheral portions, were found. The neighboring pia mater showed some infiltration of leucocytes, many of which contained pigment granules, and about some of them the pigment was found outside of the cell. Section of the left optic thalamus showed abundant extravasations of blood undergoing degeneration, with the formation of a great quantity of pigment. There were a great number of polymorphonuclear leucocytes in and about the small blood-vessels. Careful examination of many sections of the implicated tissues failed to detect the presence of micro-organisms. There was an absence of disease of any of the cranial bones, of otitis, of lesions of the scalp or face. Thrombosis of the deeper veins was absent, and there was no evidence of thrombosis of the superficial veins of the trunk or extremities. Further details of the autopsy were omitted, as the various organs were found to be normal.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, May 7, 1901.

JOSEPH COLLINS, M.D., PRESIDENT.

A Case of Successful Moral Treatment of a Form of Hysteria.—DR. MARY PUTNAM JACOBI reported this case. The patient was a woman aged twenty-four years belonging to a neurotic family. Her symptoms began four years before coming under observation, by an endometritis and a uterine retroflexion. She had been subjected to a good deal of local treatment, including curettage and an Alexander's operation. The latter procedure had relieved the dysmenorrhœa, but had been followed by a fixed pain in the abdomen not increased by pressure. She claimed to be unable to walk or stand because of severe pain in the back and abdomen which it induced. Examination showed no motor inability, and when started to walk she could do so very readily and energetically. The uterine disease had entirely disappeared. She was moderately anæmic and quite constipated. The speaker said that at some portion of the cerebro-spinal tract an area of nerve tissue must be so nearly on the border of exhaustion that an attempt at function carried it beyond this line. It was conceivable that with the exhaustion of the cerebral centre the very thought of the movement would be followed by pain. According to Sanier, such hysterical pains pointed to a partial anæsthesia in the brain. Apart from the intermittent pains excited by the sense of walking, there seemed to be a permanent and distressful sense in the back of requiring support. In a previous experience with a bed-ridden patient she had succeeded in making her walk within a week by the application of a Taylor spinal brace. This simple device had given great relief. The necessary nerve stimulus had been secured by the application of static electricity. This remedy seemed to be almost a specific for hysterical pains. The subject of the present report had been persuaded to leave her home and take a room near Dr. Jacobi's office. At first it was not difficult to get her to walk a portion of a block, but when finally asked to walk a whole block she obstinately refused. All sorts of changes in the treatment and methods of management were necessary in order to conquer the patient's wilfulness, yet this was essential to further progress. Her mode of life for each day was mapped out most minutely. By the most persistent and painstaking efforts exerted for a period of four months the patient was finally conquered. During the last eighteen months she had been living a fairly normal life. Dr. Jaobi said that in hysterics the habitual dependence upon fellow-minds was immensely intensified. To get rid of a false idea it must be starved out and atrophied by an entire lack of support from the minds of those around the patient. The essential element of the treatment of this case was the bringing of the personality of the patient under the control of another mind.

DR. B. SACHS commended the general plan of treatment described in this paper, though admitting that it required far too much expenditure of time and attention to detail to make it generally available.

DR. IRA VAN GIESON expressed his admiration for the report just presented, for, he said, it was an earnest of the time when psychological cases would be treated less by medicine and more by psychology. This case afforded an example of what could and should be done in hundreds and thousands of other similar cases. He had been particularly impressed with the statement

made concerning the necessity for causing an atrophy of each false idea—the reverse of the process by which the hysterical condition was induced. He thought the period of treatment in the case reported might perhaps have been materially reduced by suggestive therapeutics.

Dr. Jacobi said that the objection made to the treatment on the score of its time-consuming nature was hardly sufficient to condemn it. She had seen a number of cases that had gone from one physician to another without benefit, although doubtless physicians generally were well acquainted with the principles which should underlie the successful treatment of such cases.

The Morbid Anatomy of a Case of Progressive Muscular Atrophy which was Clinically one of Amyotrophic Lateral Sclerosis.—Dr. Carlin Philips read this paper. He said that the patient was a woman of thirty-six years who had come under Dr. Collins' observation for the first time on June 17, 1897. She had then complained of severe frontal headache, inability to lift the head from the pillow without the help of the hands, tremulousness of the hands, and easily induced fatigue. She had lost thirty pounds. Examination showed atrophy of the supraspinatus and of the right shoulder girdle, and these muscles showed fibrillary twitchings. The knee jerks were increased; there was ankle clonus on both sides; there was no affection of the special senses. Six months later she had complained of dyspnœa and had shown loss of will power and suicidal impulses, together with some difficulty in swallowing. The atrophy of the muscles was more marked, and extended to the trapezius muscle. She began about this time to have attacks of major hysteria, and the atrophy increased rapidly. The gait became spastic and the body rigid. She had the use of her limbs up to about six weeks before death on May 25, 1899. An autopsy was allowed only upon the brain and spinal cord. The weight of the body was forty-eight pounds. The meninges of the brain were anæmic. The brain was normal in gross appearance, as was also the spinal cord. The latter was carefully segmented and prepared in various ways for examination. In the second cervical segment was a concentric zone encircling each anterior horn and involving the anterior, mesial and anterolateral portions of the fundamental columns, while the tracts of Gowers and the pyramidal tracts were left intact. Corresponding to the degenerated areas in this segment the neurogliar proliferation was very slight. The fourth cervical segment showed a sinking in of the periphery just at the margins of the anterior roots, and this change of contour extended down several segments. The gray matter extended laterally, giving a sickle-shape to the degenerated area. While there was no evidence of the destruction of the cells, the most striking feature was the extensive destruction of these cells. The fifth cervical segment was practically the same as the fourth. The sixth segment showed a tongue-shaped area of degeneration extending almost to the posterior horn. In the seventh segment the anterior roots showed more marked degeneration. From the first to the fourth dorsal segments inclusive there was a zone of degeneration encircling the anterior horns, and becoming less intense until almost invisible in the fourth segment. The disappearance of the motor cells throughout these four segments was more difficult to determine than in the case of the cervical segments, but apparently there was about the same amount of atrophy of these cells. From the fifth to the eighth segment there appeared to be an increase in the neurogliar tissue. From the twelfth dorsal down to the end of the cord the area occupied the peripheral lamina of the ventral half of the cord, and extended around to a point opposite the apex of the lateral horn, where it expanded into a lateral mass. The lumbar and sacral regions were found to be as severely involved as the cervical. Throughout the cord the blood-vessels were apparently normal. Nissl preparations of the medulla showed small areas of periarteritis with small-cell infiltration of the adjacent gray matter. The anterior roots were found to be atrophic. The crossed pyramidal tracts were apparently unchanged.

Therapeutic Hints.

Tuberculosis.—

℞ Iodi puri cryst		1.50
Phosphori puri		0.25
Thymolis,		
Mentholis	āā	2.50
Guaiacolis		1.25
Ol. morrhuæ sterilisat		50.00

M. S. Inject one to three syringefuls once a day every four to eight days.

—Fliesburg.

Burns of the first and second degree. Apply one or two coats of a one-per-cent. solution of picric acid; allow it to dry, and then apply a thin layer of absorbent cotton; over this a layer of impervious tissue, and outside as much cotton as is required for warmth and protection. In subsequent dressings remove all except the layer next the skin, and reapply the solution.—Allen.

Nasal Turgescence with attacks of sneezing, especially in women. Apply some preparation of menthol locally, and give:

℞ Acidi arsenosi		gr. i.
Strych. sulphatis		gr. ¾
Ext. belladonnæ,		
Zinci phosphidi	āā	gr. iv
Ext. gentianæ		gr. xx.

M. ft. pil. No. xx. Sig. One pill three times a day.

—S. B. Dabney.

Arthritis Deformans.—Ice bags to the spinal column. Carbonate of guaiacol in five-grain dose three times a day, and citrate of lithium tablets.—M. G. Tull.

Guaiacol applied locally seems to be a safe and efficient remedy in relieving the pain of arthritis deformans, acute articular or muscular rheumatism, sciatica, orchitis, and epididymitis. One part of guaiacol to ten or fifteen parts of vaseline or lanolin should be applied to the painful parts.—*New England Medical Monthly.*

Ko-Sam is the native name for *Brucea sumatrana*, which has been successfully employed in dysentery (779 radical cures out of 879 cases observed). Ten grains are to be given the first day, twelve on the second, third, and fourth days. Quassine appears to be the active principle.—Broughton Knowles, *The Medical Times and Hospital Gazette*, February 16.

Habitual Constipation.—I wish to call the attention of the profession to the following statements: 1. A certain percentage of individuals suffering from habitual constipation are apt to have a spontaneous movement of the bowels the following day after the stomach has been washed for the first time. 2. The majority of such patients will eventually rceover the normal function of their bowels, if lavage is continued daily for two or three weeks, and later at greater intervals. 3. The best results are obtained from using cold water, or hot and cold water alternately. 4. The best time for such lavage is one hour before breakfast.—C. D. Spivak, *Journal of the American Medical Association*, April 13th.

Peptonized Thymus is recommended in doses of gr. xv.–xxx. in cachets or pills in chlorosis, exophthalmic goitre and congenital debility. Smaller doses may be given to children mixed with milk.—Blondel.

Malarial Coma.—In two cases there was recovery after large doses of quinine.—Acker.

Poisoning by Chloroform.—Drop upon the back of the tongue dilute hydrocyanic acid in full dose.—*Journal of Medicine and Science.*

Rosacea.—Suprarenal extract in five-grain doses from three up to six daily. The extract is simultaneously employed as a topic.—Munro.

Cold in the Head.—Potassium bicarbonate gr. xxx. every four hours in milk or water, the patient resting and being on a liquid diet for two days.—S. Harnsberger.

Antitoxin.—Before the serum treatment 54.8 per cent. of diphtheria patients recovered; now the figures are 86.92. There were 80 per cent. of recoveries in progressive croup and 57 per cent. in septic toxic cases.—Escherich.

Acromegaly.—Extract of pituitary body relieves the intense headache and materially lessens the paræsthesia which occurs during the course of the disease, but has not been shown to stop its progress.—*The Medical Press*, March 13th.

Tender Foot is sometimes cured in the West by enforced dancing. Harden recommends five-per-cent. salicylic solution, followed by two-per-cent. formic aldehyde, or a solution of the latter added to tannin and precipitated by hydrochloric acid.

Gastric Anodynes.—Atropine checks the gastric juice almost completely. Morphine increases it. When secretion is excessive as in ulcer, morphine is contraindicated and one of the belladonna preparations will act better.—Biegel, *Therapie der Gegenwart.*

Cacodylic Acid or the sodium salt by the mouth, rectum, or subcutaneously in dose of gr. ss. three times a day, gradually increased to gr. i., diminishes hectic fever, cough, difficult expectoration, and improves general nutrition, besides decreasing the hyperidrosis in phthisis.—Ewert.

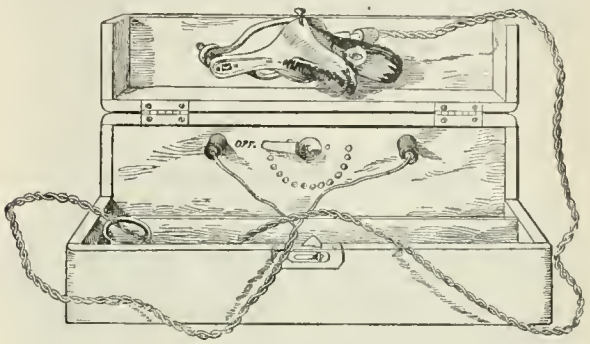
To Arrest Smallpox.—I first scrub the skin of the forearms and hands with a strongly alkaline soap and water, in order to remove the oil naturally existing in the epidermis. Then I wash the skin with alcohol to kill germs and also to remove oil. Next the skin is washed with a 1:500 solution of bichloride of mercury. Then it is washed with a solution of peroxide of hydrogen. Each of these washings is of ten or fifteen minutes' duration. Finally the parts are well wrapped in a thick envelope of borated cotton. The washing is repeated daily for three days. I would suggest, in addition, that the face and other parts to which the bath is inapplicable, should be treated by disinfectants spread on lint and applied to the skin. Also, when the patient is found poisoned by purulent infection, I should not hesitate to recommend the subcutaneous injection of antistreptococcic serum, and the administration of cathartics which have the power to produce watery alvine evacuations. For this latter purpose the sulphate of magnesium would stand foremost. Also digitalis and frequent draughts of water should be used to induce copious diuresis, thereby discharging ptomains, as would the catharsis just mentioned.—Alonzo Bryan, *The Physician and Surgeon*, January, 1901.

New Instruments.

AN ILLUMINATED VAGINAL SPECULUM.

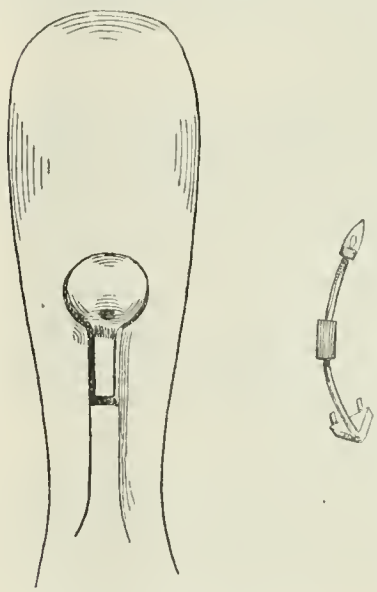
By W. J. Greanellé, M.D.,
New York.

The matter of securing sufficient light in the use of the bivalve speculum is not always a simple one,



either in private practice at the patients' homes, or even in one's office on very dark days or in the evening.

Having wrestled with this problem over and over again, and never being sufficiently satisfied with the various lamps held back of me, I hit upon the idea of carrying an electric light to the inside of the speculum, on the plan of the improved endoscope. Repeated efforts to bring this about in such a way as to meet all difficulties and requirements led finally to the elaboration of a portable case carrying a dry-cell battery, rheostat, speculum, and instruments most needed, as shown in the accompanying illustration. As here shown the anterior half of the lid is raised to provide access to the rheostat and compartments containing the speculum and instruments, the posterior half of the case containing the cells. This makes a compact and complete gynæcological diagnosis (and treatment) case.



Under Side of Upper Blade, Showing Holder for Lamp Carrier, Reflector, and Lamp.

The essential feature of the speculum lies in a tunnel, set in the anterior and lower part of the upper blade just inside the urethral opening and leading to a concave disc. The lamp carrier is made exactly and snugly to fit this tunnel, of such shape and length as to bring the lamp just within the concave disc, which acts as a reflector, throwing the light downward and inward on the cervix and deep vagina and into the fornices. The current is supplied from above, and in no way interferes with manipulations. The lamp, when *in situ*, is so placed as not to be in the way of swabs or instruments, and does not throw any light into the eye of the operator.

I have found this instrument of great value in office

work for purposes of examination and treatment, and more particularly in night work at the homes of patients, where one so often has a patient in a low bed with an overhead light, which is of absolutely no value. For handling uterine hemorrhages, curettages, and cervical ulcerations and erosions, and for post-partum examinations, the instrument is of great value. It is simple, easily cleaned, and affords one a compact gynæcological case ready to take up and carry out, being made in such proportions as to be handy (eleven by six by four inches outside measurements) and comfortable for carrying.

University Heights.

Surgical Suggestions.

Appendicitis.—It is not prudent to subject a recent scar to harmful tension at a premature time. So we make it a standing rule, to which there are no exceptions, to keep our patients in the recumbent position for at least four weeks.—Senn.

Spinal Anæsthesia has been seen by Kammerer to come on as late as forty minutes after application of the cocaine solution and yet be very complete. He usually employs about ten drops of a two-per-cent. solution.

Lime Burn of the Eye.—Cane sugar in concentrated solution forms an insoluble compound with lime, so it may be used after mechanical removal of larger particles. Cleanse every part of conjunctiva with oil, dilute vinegar or water; then use boric solution and perhaps atropine.—Posey.

Surgery in India was held in high esteem in very remote times. They had a proverb to the effect that "a physician who is no surgeon is like a bird with but one wing." They had a large assortment of steel cutting and cauterizing instruments, and held that "what drugs and knives cannot cure may be cured with fire."—Parsons.

Cosmetic Surgery has scored another triumph at the hands of a Vienna surgeon, who injects a mixture of solid and liquid vaseline to remedy disfiguring depressions and voids due to the removal of natural parts as, for example, the testicle. He employs the same method to remedy atrophy of the female breast.

Oxygenated Water, while it disinfects wounds, is painful by contact to raw surfaces, and spoils catgut sutures as well as rubber instruments and leather. In employing catgut sutures oxygenated water should be avoided, since it has even led to fatal hemorrhage.—*The Medical Press*, March 13th.

Endometritis and Salpingitis.—One knows by experience that if one gets the endometrium and the pouch leading to the Fallopian tube into a healthy state, the Fallopian tube almost always recovers itself if merely in a state of chronic inflammation.—Amand Routh.

Cocaine in equal parts of almond and petroleum oil, while it is slower to begin, continues to act longer than the water solution. Two per cent. is strong enough for nose and throat work. A five-per-cent. watery solution with two per cent. of sodium sulphate added acts better by reason of the penetrating power and solvent action upon globulins and proteids of the secretions encountered.—Wingrave.

Popliteal Aneurism.—The case is given of a negro aged forty-two, who had an aneurism situated on the popliteal artery, about the size of a hen egg. The treatment was digital compression, kept up for thirty-six hours by relays of medical students. A splint was applied for three or four days, and in a week the patient was allowed to get up.—Hamann.

Nasal Discharges in Children.—Do not diagnose accessory sinus trouble before the sinuses are developed; remember that the frontal sinus is not developed until the seventh year; that the antrum, although developed early, is quite small until after the second dentition, and that the ethmoidal cells have not bony walls until the fourth year, and at that age they are quite small.—Cobbledick.

Foreign Body in the Ear.—The rubber end of a pencil was extracted by teasing out the end of a small piece of twine, and giving this a good coating of glue, pushing it tightly against the India rubber, and packing it closely all round with cotton wool. This was allowed to remain in position for twenty-four hours, when there was firm cohesion, and not the slightest difficulty was found in withdrawing everything *en masse*.—Macaskie.

Benson relates an instance of the end of a slate pencil being retained and causing deafness for twenty-five years, and Cullen one in which for thirty years a pea-sized piece of tortoise shell had pressed upon the tympanic membrane. In both patients normal hearing was restored.

Disinfection of Soft Catheters.—(1) The disinfection of catheters with bichloride of mercury is unsatisfactory. (2) The use of live steam for the disinfection of catheters is also unsatisfactory, because of the damage done the catheters. (3) The disinfection of catheters with formaldehyde vapor as hitherto practised is too slow and for catheters of small calibre incomplete. (4) The apparatus devised by the writer enables one to render all sizes of catheters absolutely sterile in from ten to twenty-five minutes without any injury to the catheters, by the use of a strong vapor of pure trioxymethylene powder.—Katzenstein, *Berliner klinische Wochenschrift*, September 10, 1900.

Spinal Abscess.—Do not wait to open a spinal abscess until the skin is reddened and involved. So far as possible open the abscess at certain seats of election, *i.e.*, away from the groin, and make more than one opening if possible. Carefully cleanse the cavity and rub the interior thoroughly with menthol or iodoform solution. Avoid drains of all kinds, and be careful to carry out perfect aseptic measures from first to last. Some patients improve by rest alone, the fluid portion of the pus becoming absorbed, but in many cases the abscess makes its way toward the surface, and then operation should be performed at once, before the skin and subcutaneous tissue have become infected by tubercle, or a persistent sinus may remain.—A. H. Tubby, quoted in *Medical Times and Hospital Gazette*, February 23d.

Cleft Palate.—A modified operation especially adapted to young children includes a curved incision on each side close to the alveolar margin of the palate, commencing posteriorly inside the last molar tooth and curving round anteriorly to terminate in the cleft, and arranged at the same time in such a way that sufficient tissue is left immediately behind the incisor teeth to hold a suture subsequently. With this incision the posterior palatine artery is retained in the flap. The latter is reflected by means of a rugine. The connections between the hard and soft palates are then severed by turning back the flaps which have been al-

ready detached from the hard palate. Silkworm-gut sutures are used, the first being placed posteriorly. At the anterior extremity of the cleft the suture should be passed through the flap from its mucous to its periosteal aspect; the free end of the suture is then carried through the gum behind the incisor teeth in the reversed direction, viz., from its deep to its superficial aspect. This suture anchors the flaps in front during the process of healing.—E. H. Taylor, *Dublin Journal of Medical Science*, January 5th.

Chronic Nasal Suppuration may be caused by (1) Suppuration in one or more of the accessory sinuses. (2) Bony necrosis, usually syphilitic in origin. (3) Foreign bodies and adenoids. These are usually found in children, but it should be remembered that the accessory sinuses are liable to disease in children as well as in adults. A purulent discharge in children may be due, during the first few years of life, to an unknown cause, the naso-pharynx being quite clear and the accessory sinuses undeveloped.—Cobbledick.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 25, 1901:

	Cases.	Deaths.
Tuberculosis	259	163
Typhoid fever	27	5
Scarlet fever	610	32
Measles	302	10
Diphtheria and croup	296	40
Smallpox	134	13
Chickenpox	92	0
Cerebro-spinal meningitis	0	4

Recent Legislation of Interest to the Medical Profession.—Albany, N. Y., May, 1901. Of course the most interesting bill, to medical men, that came before the last legislature of New York was the one regulating and legalizing the practice of osteopathy in the State of New York, and fixing penalties for the violation thereof. This bill was amended several times, and finally provided that a person must pass a satisfactory examination before the State board of health in order to practise, and also providing that no person of this sort should prescribe medicines or drugs in treatment of diseases. The bill, it is needless to say, never reached the governor.

An attempt was made to repeal the present law to protect the public health by regulating the teaching and practice of hypnotism and mesmerism, and to enact in its stead more liberal provisions for the practice of the same. This bill also failed, as did also an amendment to the public health law, providing that no person shall be regarded as practising medicine who shall use any kind of treatment or appliances. Still another bill failed amending the public health law so as to allow the practice of massage, mechano-therapy, hydro-therapy, and electro-therapy, under proper restrictions of licenses and registry. The chief amendment to the public health law enacted was that abolishing the old and cumbersome State board of health, and creating a new State department of health under a single commission. The commissioner holds office for four years, and has a salary of $3,500. This is certainly a very great improvement upon the former way.

An amendment to the public health law was offered, allowing the regents of the university to admit to an examination students who had not pursued their studies as far as is required at present. This did not pass, neither did a bill permitting the Civil Service Commission to certify for appointment any physician in the State hospitals' service who shall have served in such position for three years. The public health law was amended so as to allow country stores to sell Epsom and Rochelle salts without a druggist's license; also, allowing physicians to compound prescriptions and sell poisons where there is no drug store within three miles. Amendments to the same law failed relative to the practice of pharmacy in State institutions and to the registration of pharmacists and drug stores; and a general amendment to the section of the law relating to pharmacy also failed.

The public health law was also amended so as to make much more stringent all of its provisions in relation to the practice of dentistry, and to incorporate therein the statutes relating to dental societies.

Among the other amendments to the public health law which failed were these:

Providing that town boards of health shall be appointed bi-annually instead of annually.

Providing that the State board of health shall enforce a provision requiring all books and newspapers to be published in larger type; and giving the authorities of hospitals, prisons, etc., in certain interior counties of the State authority to deliver cadavers to medical colleges.

The city of Rochester was given authority to remove all sources of pollution of its water supply; but a bill amending the public health law, by providing for the appointment of a chief inspector of plumbing and drainage in certain cities, did not pass.

None of the bills relating to the adulteration of food became laws. One of them amended the public health law so as to include beverages with foods; another amended the agricultural law by inserting a new article prohibiting the manufacture or sale of adulterated food, and a third sought to prevent the use of unhealthy chemicals or substances in the preparation or manufacture of any article used or to be used in the preparation of foods. What is known as the "pure beer" bill, an amendment to the public health law, did not pass.

An amendment to the agricultural law was offered, but did not pass. Its design was relative to diseases of domestic animals; to repeal article four of the public health law and incorporate in its stead certain provisions of the agricultural law relating to the public health, and making an appropriation to carry out the provisions of this act. A similar fate overtook a bill for the protection of the public health by preventing contagious diseases from spreading through the use of old bottles.

An amendment to the insanity law was passed, providing that the president of the State commission in lunacy shall be a physician of ten years' experience in the practice of his profession, and who has had five years' experience in the treatment of mental and nervous diseases or two years' experience in the treatment of committed insane, and fixing the salaries of the commissioners in lunacy at $5,000 a year and $1,200 for travelling expenses.

The public health law was amended by providing that any person who received his degree from a reputable veterinary school prior to January 1, 1897, or who practised veterinary medicine prior to 1896, shall be admitted to the State veterinary licensed examination without further requirements.

A bill failed to pass establishing a State veterinary college for the eastern portion of the State at New York University in the city of New York, and to provide for the administration thereof.

An appropriation of about $35,000 was made for the

quarantine stations at Hoffman and Swinburne islands, and another appropriation of $5,000 was made for the care, maintenance, and repairs of the quarantine establishment at the quarantine station. An amendment to the penal code failed to pass, making it a misdemeanor to go on board vessels at quarantine grounds.

A bill exempting from taxation the property of certain medical societies situated in cities of the first class failed to pass; as did also an amendment to the consolidated school law, relative to teaching physiology, hygiene, and the effects of narcotics.

A bill was passed authorizing the board of estimate and apportionment of New York to pay certain persons for services in the department of public charities, pending the preparation of an eligible list for apothecaries and nurses.

An amendment was passed to the law establishing a State hospital for the care of crippled and deformed children, so as to give more authority to the first assistant surgeon; and another amendment to the law was passed, providing for the annual submission of estimates for appropriations by the New York State Hospital for the care of crippled and deformed children. An appropriation of about $500 was made for the institution.

An appropriation of $10,000 was made for the construction of buildings for the New York State Hospital, for the treatment of incipient pulmonary tuberculosis. A bill was passed relative to the payment to the Pasteur Institute of New York, for services in caring for poor persons in danger of infection with rabies. The charter of the Albany hospital was amended by increasing the powers of the board of governors and making necessary a majority vote of all the governors elected for the suspending or discharging of any member of the medical staff. The common council of Lockport was authorized to raise $5,000 to erect a hospital; and the appropriations made by the board of supervisors of Rockland County for the support and maintenance of inmates of the Nyack hospital were authorized.

A bill failed, allowing the Montefiore Home for Chronic Invalids to maintain a home for chronic invalids and a hospital and dispensary in the city of New York, and one or more sanatoria for consumptives in the State of New York.

Hospital bills failed as follows:

Providing for the construction of a building for hospital purposes and acquiring land for the same in the Borough of the Bronx in the city of New York; providing for a hospital for the special treatment of acute nervous and mental diseases within the city and county of New York; and amending an act to establish a State hospital in some suitable location in the Adirondacks for the treatment of incipient pulmonary tuberculosis, and making an appropriation therefor.

Isolation in Relation to Typhoid Fever.—Dr. Alfred Hill, medical officer of health, Birmingham, England, says: "There can be no doubt that the most important step to be taken at the present time for the prevention of typhoid fever is to provide for the removal to hospital of all patients who cannot be properly isolated at home. The need for a larger number of removals is clearly shown from the fact that 244, or about two-thirds of the cases, were treated at home in the past quarter. Moreover, 101 of the cases treated at home lived in houses with two bedrooms and one living-room only, and a number of these houses contained as many as seven other persons besides the patient. The effect of removal to hospital is very great in preventing further cases in the same house and among the patients' friends and relatives. But it is also most noticeable in increasing the patient's chance of recovery. Thus in the quarter under review, of the patients treated in hospital only 12 per cent. died, while 24 per cent. of the cases treated at home succumbed to the disease. This is not surprising when it is remembered that a great many cases occurred in the homes of the poor, where skilful nursing, suitable diet, and good hygienic surroundings are not generally available."

The Distribution of Beri-Beri in India.—The sanitary commissioner with the government of India draws attention in his last report to the significant fact that, although beri-beri disease has long existed in Burmah, and occurs in certain districts of Madras, no case of it has ever been recorded in the wheat-eating areas of India. In Rangoon, Hindoo natives of India appear to suffer most. Those attacked belong almost entirely to the coolie class, chiefly from Southern India, and are generally people whose diet, though it may be plentiful, is very deficient in nitrogenous elements. In the past three years close upon one thousand cases of beri-beri have been admitted into the Rangoon hospital, very little more than half of them resulting in recovery. The death rate indeed is returned at forty-eight per cent. of the nine hundred and forty-four cases registered. This means more than four hundred deaths. —*Sanitary Record.*

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended May 17, 1901:

		Cases.	Deaths.
Smallpox—United States and Insular.			
Alaska, Hoonah	May 11th	..	15
Killisnoo	May 11th	4	
California, Los Angeles	April 27th to May 11th	12	
San Francisco	May 4th to 11th	6	
Illinois, Chicago	May 11th to 18th	6	
Indian Territory, Coalgate	May 11th	65	
Kansas, Wichita	May 4th to 18th	37

THE PRESIDENT'S ADDRESS.

DELIVERED AT THE FIFTY-SECOND ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ST. PAUL, MINN., JUNE 4-7, 1901.

BY CHARLES A. L. REED, A.M., M.D.,

CINCINNATI, OHIO.

IN approaching the discharge of my duties as presiding officer of the fifty-second session of the American Medical Association, I beg to express my appreciation of the generous suffrages by which I have been called to a position of such conspicuous honor. This appreciation becomes all the more pronounced when I reflect upon the magnitude and achievements of this great national body and upon the lustre of the distinguished men who have presided over its deliberations. This thought brings me to the first duty of the occasion, and that is, officially to bring to your attention the fact that since our last reunion three of my most illustrious predecessors have been called from their worldly activities to the realm of rewards. Alfred Stillé, Lewis A. Sayre, and Hunter McGuire, each a former president of the association, died within a single week. Their lives were known of men, their records are ornaments of our annals, and their achievements are their eulogies. They labored zealously and with beneficent results, not alone in the scientific field, but in behalf of an organized national profession; and to guard zealously the splendid legacy which they, among others, have left us, must be one object of our labors upon this auspicious occasion. The hope is indulged that steps may be taken to procure suitable portraits of these and of other deceased presidents of the association, to be placed in some safe gallery until such time as the Association may be able to transfer them to its own Temple of Fame. I recommend that suitable formal action be taken on this occasion relative to the life, distinguished services, and the death of these lamented *confrères*.

Foreign Relations.—The American Medical Association accredited delegates during the last year to several foreign medical conventions, notably the International Medical Congress at Paris, the Dominion Medical Association of Canada, the Mexican National Association, and the Pan-American Medical Congress at Havana. To each of these organizations the American Medical Association sustains relations of peculiar intimacy. As one of the great scientific nations of the earth, the United States is naturally an integral part of the International Medical Congress. This association, by a resolution presented by your present executive officer, took the initiative in 1891, in organizing the Pan-American Medical Congress. The first reunion of that congress was held in Washington in 1893, under the presidency of the late lamented Dr. William Pepper. The second was held in the city of Mexico in 1896 under the presidency of Dr. Carmona y Valle, while the third has been held during the last few months in the city of Havana under the distinguished presidency of Dr. Juan Santos Fernandez. This movement has for its object the establishment of closer relations between the medical profession of the different countries of the western hemisphere. It has already borne excellent fruit in the increased patronage of our medical schools from the far south, in the improved status of American medical practitioners in Latin America, in a better understanding of quarantine questions in the different countries, and in the development of a concert in the investigation of the medicinal flora of the western hemisphere. Our relations with the medical profession of Canada must be of increasing intimacy, and I indulge the hope that while maintaining the national limitations of our association for delegate and legislative purposes, its membership, with the privilege of participating in all scientific matters, may be freely opened to our brethren who live beyond our immediate borders.

Fiscal Affairs and the Journal.—It has passed into unwritten law, born of the gradually developing features of our organization, that your president shall restrict his annual address to a discussion of affairs of the association and to the great object to which, by the terms of its constitution, it stands consecrated—"the common interests of the medical profession in every part of the United States." In compliance with this rule, and realizing that I am leaving scientific questions to be presented by orators appointed for the purpose, I have pleasure in calling your attention to the satisfactory condition of the affairs of the association, as indicated by the consolidated report of the treasurer and of the board of trustees. From it you will observe that under the judicious management of your board of trustees you have a cash balance at the end of the last fiscal year of $31,004.67, being an excess of $3,696.66 over the preceding year. Your plant has been increased in value to the amount of nearly $10,000, and the net profits of *The Journal* amounted to nearly $14,000. You will be gratified to realize that, in addition, you have safely invested, as part of a fund with which to buy a home for *The Journal* and for the association, the respectable sum of $25,000. If, however, you have occasion to feel satisfied with the normal condition of your finances, you must contemplate with pride the rapid increase of your journal, in quality, size, circulation, and influence. The average weekly circulation grew, during the last fiscal year, from 13,672 to 17,446, and I have added pleasure in informing you that, since the period covered by the report, the weekly circulation has grown to 22,000 copies. For the accomplishment of these splendid results, I feel that you will join me in hearty acknowledgment, not only of the sagacious management by the board of trustees, but the tireless industry and the discreet direction of our accomplished editor, Dr. George H. Simmons.

I feel that it is important, however, to call your attention to the fact that it would have been impossible for your board of trustees to accomplish these results if, through its action, the association had not become incorporated. Leases were to be executed, purchases were to be made, contracts were to be entered into, money was to be loaned, and bonds were to be exacted, to do all of which it was necessary that the association

should become a legally organized corporation. This was effected, *ad interim*, by the action of your board of trustees, which procured articles of incorporation under the laws of Illinois, bearing date of April 14, 1897. I am not aware that this fact, attested by the document which I have laid before the executive committee, has ever been confirmed by the vote of the association. I recommend, therefore, that such action be taken at the present session.

If, however, the condition of the association, and particularly of *The Journal*, is, on the whole, occasion for much satisfaction, certain facts revealed by the report are food for thought. Thus, *The Journal* has an aggregate circulation two and one-half times greater than the aggregate membership of the association. It would seem, therefore, that while the profession at large prizes *The Journal*, it places relatively less than half as much value upon membership in the association. This fact becomes strikingly significant when it is remembered that membership can be acquired by those who are eligible at no additional expense and with but trifling inconvenience. Does *The Journal* fulfil all the wants of the profession arising in connection with the association? Are there no additional advantages to be derived from membership? Is there a lack of *esprit de corps*—a lack of the sense of unity in the profession? Is the existing basis of our national organization distasteful to the majority of the practitioners? Do our subscribers embrace a considerable number of practitioners who, under existing rules, cannot become members, and whose influence, therefore, cannot be secured in behalf of the association? These are questions that I am at liberty to ask, and that you are at liberty to answer.

Another thought suggested by the report relates to the disposition of the accumulating surplus. Shall the present policy for creating a fund for the purchase of property be carried out? Shall a larger proportion of the money be expended in still further exploiting *The Journal?* Shall the members receive a direct advantage from the earnings of the property which they have created, by reducing the annual dues, or shall a certain proportion of our surplus be expended in conducting original scientific investigations on subjects of universal interest to the profession? I cannot resist the temptation in this connection to venture replies to these questions far enough to say that, in my opinion, a reserve should be held in hand large enough to meet any possible contingencies that might occur by fire or other disaster in connection with *The Journal;* that the present generous policy in promoting the welfare of *The Journal* should be continued; that the dues of the association should not be decreased; and that the question of establishing and defraying the expenses of certain commissions for special scientific investigators should be taken under serious consideration. The question of tuberculosis is not yet a closed chapter. The causation of cancer is yet a sealed mystery. The problems of tenement-house reform are not yet solved. The prevention of various endemic diseases has not yet been made practicable. The systematic investigation of the American medicinal flora, begun under the auspices of this association more than forty years ago, remains an uncompleted task. These are a few among the many objects of a specific character which demand and should receive the fostering care of the association.

I feel, however, that at the present moment, and under the existing features of our organization, it would be almost impossible to determine judiciously either of these very important questions, and I now bring them before the association only for the purpose of directing attention to them, with the hope that they may be taken up subsequently and under more auspicious circumstances.

Scientific Work.—The association began its career with general meetings devoted chiefly to questions of medical education and professional conduct, and to lengthy reports from various standing committees. In 1860 it divided itself into a few sections, each with a certain autonomy, and each devoted to a particular part of our great scientific work. This change was followed by the establishment of the judicial council, by which means controversial questions, many of them of a personal character, were eliminated from the general meetings. The subsequent creation of the executive committee still further relieved the general meetings of annoying details. Thus relieved, both the general meetings and the sections have grown in scientific importance, emphasizing the persistence of our devotion to what must ever be recognized as the essential, fundamental object of our organization—the cultivation of the medical sciences. It must be acknowledged, however, that great as has been the progress in this particular, too much of the time of our general sessions is yet devoted to the consideration of matters which might, with propriety, be relegated for final action to a smaller body. It would redound largely to the interest of our annual session if the general membership could be entertained and instructed at our general meetings by exercises of a more purely scientific character, of such broad nature that they should not be restricted to any of the sections. A reform in this particular will be a long step in the direction of progress. The sections, in consequence of the faithful labors of their officers, offer strikingly attractive programmes for the present session. In several of the lists will be found the names of invited guests who, through fortuitous circumstances, are not members of the association, but who are, nevertheless, active workers in the scientific field, and whose participation in our labors will enrich the value of our proceedings and enhance the felicities of the occasion. I bespeak for them your cordial welcome. While the officers of sections and your president have exercised the prerogative of inviting guests, who come as guests, and not as members of any class as specified by the constitution, such invitations have been extended solely with the object of advancing the interests of the association. I look upon this privilege, which has been exercised by all of my predecessors and by previous officers of sections, as one of extreme importance, and one which should be continued under any plan of reorganization which may be adopted. It is my conviction, however, that the privilege should be hedged about by certain limitations, one of the most important of which should be that an invitation should not be extended a second time to any person residing within the United States, whose professional qualifications may entitle him to membership. With reference to the invitation of persons identified with the allied sciences, the matter should be left absolutely to the discretion of the president of the association and with the officers of sections.

Legislative Affairs.—The American Medical Association, during the first fifty years of its existence, exerted relatively little influence upon legislation, either State or national. Since the standing committee on national legislation and the national legislative council of delegates from the State societies have been established, and have become co-operative, there is some evidence that the voice of the profession is heeded at Washington. The experience of the splendid committee of the association, acting in concert with the national legislative council during the last year, has, however, shown the serious necessity for more thorough organization in protecting the interests of the profession, and the interests of society as represented through the profession. The inefficiency of our present organization for influence upon Congress was

shown in the inability of your committee, notwithstanding its strong *personnel* and the influences at its command, to prevent the degradation of the army medical service. This was accomplished by the passage of a bill under the championship of Senator Hawley, by the terms of which the medical corps of the army is subjected to unfair and humiliating discrimination. This law grades the medical department for rank, promotion, and, in consequence, for pay, below every other department and special corps of the army, and, with the exception of second lieutenants, it is graded below the line. In accordance with its provisions, a medical officer, to obtain a colonelcy, must pass through three times as many files as an officer of either the quartermaster's, the subsistence, or the pay departments; more than twice as many as an officer of engineers or of ordnance, and nearly twice as many as an officer of the signal corps. The effect of this discrimination is not only to lower the rank and pay of medical officers, but must result in lessening the efficiency of the corps by repelling men of spirit and worth.

In every war known to history the deaths from preventable diseases have exceeded those due to battle. At no time has hygienic science been so resourceful as at present in preventing disease. A law which fails to give to armies, either in peace or in war, the fullest protection by the application of the latest scientific developments at the hands of specially trained medical men is unjust to the soldier, to society, and to the medical profession. In view of these facts, the army reorganization law of the last Congress was inexplicable and inexcusable. It, however, forces itself upon your consideration from another standpoint. Physicians are citizens of the republic. As such they are intellectually, socially, politically, and officially the equals of any other element of the body politic. There is no station to which they may not attain; there is no distinction of which they may not be the recipients. Their rights are of manhood origin, and their prerogatives are inherent. They are, in very fact, peers of the realm, and the peers of any peers of any realm. When the status of any number of physicians in their representative relationship to society is lowered, the status of the medical profession in general is menaced in corresponding degree. When the Congress, by the enactment of a law, degrades, relatively, the status of an important body of medical men, engaged in the public service, it strikes at the status of every physician in the country. It becomes, therefore, the duty of every member of the medical profession, jealous of his rights, his prerogatives, and the fair name he may leave his children, to resent as personal between himself and every member of the Congress who voted for this law, the action which cast a stigma upon our profession.

It has been the conviction of many enlightened members of the medical profession that the means employed by the general government for the protection and promotion of the public health are capable of improvement. These duties have devolved upon the Marine-Hospital service, which was originally designed to give succor to unfortunate people, without other domicile, who were employed upon our rivers, lakes, and the high seas. With the growth of sanitary science this service, being the only established agency available by the government for this purpose, has been largely diverted from its original object. As a result, under the present wise administration of its surgeon-general, its representatives are abroad investigating the sanitary condition of foreign cities, its agents are at our ports beating back threatened epidemics, while valuable investigations are being conducted in its laboratories. In the exercise of its quarantine functions, however, it comes in conflict with the police power that is guaranteed by the Constitution to the different States. The friction thus engender d has been especially marked in the seaboard States While this is true, the Marine-Hospital service, in scope and design, does not fulfil in highest degree the objects of a central co-ordinating agency for the protection of the public health. It was thought to create a department of public health, with its executive officer in the cabinet, but this idea yielded to that of a bureau in charge of a large advisory council, composed of representatives from the various States. Resolutions have been adopted and memorials have been sent to the Congress, committees have been appointed, money has been appropriated by this association; bills have been introduced, and hearings have been had in committee, with the result that the conditions to-day are precisely the same that they were ten years ago, when the agitation was inaugurated in the session of this association held at Washington.

Secretary Wilson, of the Department of Agriculture, in his report for 1899, recommended that the Congress appropriate money to defray the expense of a systematic investigation of the medicinal flora of the United States, and of experiments upon the naturalization of medicinal plants indigenous to other countries. This recommendation was based upon the fact that the United States is the only great country which either has not conducted or is not conducting such experiments, and upon the fact that the proposed measure, touching the avenues of industry, manufacture, commerce, and the public health, was one of national concern. This measure, however, with its manifest importance, was denied even courteous consideration, while its friends were denied a hearing by the committees of the Congress.

The cause of failure on the part of this association to procure legislation by the Congress—and with the exception of preventing the passage of the antivivisection bill last year and securing the enactment of the quarantine bill this year, our recent efforts must be recognized as failures—I say the causes of our failure are properly subjects for careful consideration. I have examined the records of the association from the date of its organization, and have been profoundly impressed with the fact that memorials, resolutions, or even more definite propositions addressed to the Congress have, for the most part, represented the views, or rather the impressions, of the individual members proposing them. They have generally been presented in the general meeting, and have been indorsed without the deliberation essential for wise action; but a deliberation which is simply impossible in the limited time available in our general meetings. In certain instances memorials to the Congress have been presented at one session of the association, have been reported to committees and reported back for action, either at a later meeting of the same session or at the succeeding annual session of the association. But it becomes evident that this course lessens the evil but a trifle, for the reason that the committees to which such matters were referred have been constituted either under the leadership of the member proposing the measure or of members of a standing committee who had no interest in or understanding of the proposed measure. Such memorials, resolutions, or propositions, when acted upon affirmatively by the general meeting of the association, have, possibly, been mailed to some member of Congress or of a legislature, but were not followed by effective work in the rank and file of the profession or among their patrons. When such bills have been presented to the Congress, and have received a certain amount of support from representatives of this association, they have, as a rule, attained only that degree of importance that have made them valuable to their ostensible champions, as some-

thing to trade in the game and barter of legislation for something which would please a larger number of constituents and command a larger number of votes. In view of the fact that, after all, the argument of votes is the only one which appeals effectively to the average congressman, it behooves this association, in its efforts to conserve the interests of the profession and of society, to put itself in position to influence the largest number of votes. Every physician, therefore, should, in a perfectly respectable sense, become an active working politician. This subject, however, is of such breadth and of such depth that it may be well for us to pause at this juncture long enough to consider, from the standpoint of fundamental facts, the relationship of physicians to each other, and of the medical profession in the aggregate as an integral factor in society.

The Profession, the Association, and the Commonwealth.—In approaching a study, however brief, of the relation of the medical profession to the state, or, as I prefer to call it, the commonwealth, I feel that I am inviting your attention to an eminently practical theme; one which may enable us to understand the influences by which we have arrived at our present estate, and the means by which we may advance to even greater achievements. As we approach this theme —this eminently practical theme—we discover that the status of the medical profession, like that of every other element of that complex whole which we call society, is a perfectly natural one. Whatever it may be, it has been attained in the process of evolution, and has been, and is, determined by laws as immutable as those which govern the commingling of atoms or the sidereal strides of the planets. It is not the result of conventions or of resolutions or of statutory enactments; but these are to be interpreted rather as *indiciæ*, for the time being, of the position of the profession in the body politic. They are, indeed, consequences rather than causes, and as such they are subjects for careful inquiry. It is by a study of them that we are enabled in part to determine those laws, those natural laws, our harmony with which is essential, not alone for the present usefulness and continued progress of the profession, but for the ability of the medical profession to conserve the welfare and promote the happiness of society at large.

But I have said that the position of the medical profession is a natural one. The truth of this declaration is apparent when we go back to the beginnings of society—when we examine the evidences presented by primitive peoples. We are familiar with the classic example so frequently utilized as a starting-point in the discussion of sociologic phenomena—the example of the two aborigines, one of whom makes better arrows and the other better mats than his companion, when, presently, one confines himself to arrows, the other to mats, each trading his own for the other's product. Here is an example of the beginning of what the scientists call "specialization of function in the social organism." It is an interesting process, which, based upon varying necessities and diverse aptitudes, results in multiplication of handicraft until somebody is hurt. This is a new necessity, and it is met by a new aptitude, and the possessor of that aptitude—the medicine man, our honored progenitor—steps upon the scene. His companions, appreciating his services, reward him with their arrows and mats; and he, finding the life to his liking, restricts himself to his new-found vocation—and the medical profession is established! As the necessity for his services, whether of charm or incantation, becomes more apparent, the esteem of his fellows becomes more pronounced. As events progress he is accorded certain rights, given certain prerogatives, and hedged about by certain limitations, all calculated to increase his efficiency in promoting the common welfare—and thus is the practice of medicine regulated. He is spared from the battle that he may serve his companions, and he stays away from the chase that he may delve into the great mysteries—and thus is medical education inaugurated. He is the exponent, not only of his professional knowledge, but of at least the average intelligence of his people. He is, in short, an integral part of the primitive social fabric. As such, he shares the manners, the customs, the aims, the ambitions of his companions; and he, with them, is controlled by the forces which determine the common state and the common destiny. His status is, therefore, determined by the very laws which control the growth and development of society itself. So true is this that, from the dawn of history until the present day, and in every stage of sociologic development, the civilization of a people may be infallibly determined by the intelligence, the efficiency, and the influence of its medical profession.

The Medical Profession and Society Fifty Years Ago.—It would not be to our present purpose to follow the evolution of society as exemplified in any of the civilized people, or, as the scientists say, "distinct ethnic entities of the world," in which the present complexity has been attained by an orderly succession of events. And it would be equally unnecessary to show, what everybody knows, that the medical profession, the heritor, in common with others, of antecedent influences, has been propelled by the same forces and by equally orderly events to precisely the same standard of civilization. The lesson before us is that of the relation of the medical profession to a society, which, but a few decades ago, was the most diverse in origin and the most heterogeneous in constitution known to modern history; but a society which at the dawn of the twentieth century is one of the largest, richest, and most intelligent of the world, a society well amalgamated, and which by common consent of even adverse critics is moving in harmony with the most advanced influences of civilization. I fancy I should suddenly find myself unpopular with the audience if I were to intimate that you, who comprise it—that you, the representatives of the medical profession —have failed to contribute your full quota to the great progress which that society in general has achieved, or that you do not reflect in intelligence and morality the highest type of civilized man. I hasten to allay your apprehension, for I have no such intention. On the contrary, I ask you to indulge with me in a retrospect of American society during the last half-dozen decades, that we may the better understand the important part that you, and the profession that you represent, have played in the attainment of present results.

As I have already stated, the middle of the nineteenth century found diverse conditions of society in the United States. The older cities of the seaboard were the centres of an advanced civilization. The remoter counties of the same State, however, were then, in the absence of railroads, the telegraph and modern mail facilities, more remote from the centres of American influence than is St. Paul to-day from St. Petersburg. The great tide of emigration that had already poured and was yet pouring over the mountains and spreading in lonely habitations or widely separated communities over the vast valley of the Mississippi from the lakes to the Gulf was busily engaged with the serious problem of existence. The forest was to be felled and the prairie was to be subjugated, habitations were to be built and crops were to be raised. In the midst of these exactions, institutions of higher learning were established, and to an extent patronized, and some strong men were produced. But it must be recognized as true that society in general had but little time and less money to devote either to schooling

or to the amenities of life. The medical profession, under these circumstances, was precisely like the community of which it was a part. There were but few medical colleges, and they, for the most part, were but meagrely equipped. Many doctors became such while going from one town to another. Ignorant inventors of alleged systems of cure hawked their wares in the highways and the by-ways. Dogmatism that was destructive to intelligence was rampant, while schism was fostered by the baneful commercialism that too generally pervaded the heterogeneous mass of forty thousand people that comprised the medical profession. In eight of the twenty-six then existing States no laws affecting medical practice had ever been enacted; in eleven, laws previously enacted had been repealed; in three only were there any restrictive laws, and these proved inefficient; while the facts could not be ascertained relative to the remaining four States.

The Era of Attempted Voluntary Regulation of Medical Practice.—To remedy these evils, and actuated by the love of science, the promptings of self-interest, and by devotion to the interests of humanity, representatives of the various State medical societies met in convention over half a century ago and organized the American Medical Association, with the avowed object of having its members represent and take cognizance of "the common interest of the medical profession in every part of the United States." It sought to cultivate medical knowledge among its members, to elevate the standard of medical education, to promote the honor and influence and interests of the medical profession, and to enlighten the public concerning the relation between the medical profession and society. Emulation and concert of action in the profession and friendly intercourse among those engaged in it were additional aims of the founders of this great body of representative American medical practitioners. A constitution, by-laws, and certain rules of conduct were adopted. The constitution provided for a delegate body, delegates being accredited from recognized medical societies, medical schools, and eleemosynary institutions. The rules of conduct prescribed in detail the deportment of a physician, the deportment of the patient, interdicted the licensure of sectarian physicians, and proscribed from consultation those whose practice was based upon an exclusive dogma. The influence of the new association was extended chiefly through the avenues of the various State societies, many of which adopted the rules of conduct that had been prescribed by the newly formed national body as the basis of affiliation. Several of the State societies, notably those of Massachusetts, Rhode Island, and Mississippi, finding either that the prescribed rules of conduct were not suitable to their respective local conditions, or feeling that they were sufficiently in touch with the ordinary forces of civilization to require no such formulæ, never adopted the rules of conduct prescribed by the national body. The medical association of Alabama adopted the rules with rather a *naïve* proviso that somebody be appointed to call attention to such of the special teachings of these rules "as may seem to require elucidation in view of special circumstances and conditions." Other State societies adopted more or less modifying resolutions, but the general spirit of ostracism and aloofness was maintained during the succeeding three decades. The result of this movement was immediately salutary; it developed an *esprit de corps* in the great body of the profession; it gave an authoritative definition to medical education, and it created a strong and influential national body within the profession. At the same time, however, it became apparent that the organization did not possess the necessary inherent strength to accomplish its avowed object to regulate the practice of medicine. As time passed schismatic medicine grew apace, its colleges multiplied, its practitioners appeared all over the country, exemplifying that law that always makes the blood of the martyrs the seed of the church. Quackery of the most flagrant character was found everywhere, and society was unprotected from its ravages, while the inability of a voluntary, unchartered organization to enact and to execute penary laws was reduced to a demonstration. The medical profession, as an organized body, discovered that its relation to the commonwealth was, as the result of its own proscriptive policy, scarcely more intimate or more influential than at the beginning of the thirty years' hopeless experiment.

The Era of Effective Legislative Control of Medical Practice.—The era of effective legislative control of medical practice came as the natural reaction from the demonstrated failure to accomplish the same result through voluntary organization; but it came as the result of the sentiment which had been propagated largely through the influence of this association. The representatives of progressive medicine, turning from the national association, invoked the aid of their respective State societies in taking up the question with their respective legislatures. The profession in each State, however, recognizing its own local conditions, proceeded in its own way to attend to its own business. The very earliest attempts to secure State legislation revealed the fact that the so-called irregular practitioners, under the stimulus of ostracism and the fostering care of public sympathy thereby induced, had become so numerous and so influential that in the majority of States nothing could be done without their co-operation. It was no longer a theory but a condition with which the real reformers were confronted—and they met it. California, in 1876, through its regular medical society, took the initiative. After conferences with the representatives of the sectarian societies, and after securing their co-operation, a law was procured creating a licensing board composed of representatives of both the regular and sectarian schools of practice. Illinois, confronted by precisely the same condition, took precisely the same course. Alabama, always progressive, but the happy possessor of other conditions, was able to place the regulation of medical practice for the time being under the control of its incomparable State medical association. Colorado created a mixed board. New York, confronted by conditions even more complicated than those in other States, took up the same task. The profession of that State, acting through its organized body, containing among its members many of the most honored and illustrious names in American medicine, found it doubly necessary to enter into treaty with the denominational physicians. It realized, however, that the rules of conduct to which it had always conformed contained, among other provisions, one which made it unlawful to "examine or sign diplomas or certificates of proficiency for, or otherwise be especially concerned with, the graduation of, persons whom they had good reason to believe intend to support and practise an exclusive and irregular system of medicine."

As the thing expressly interdicted by this rule was the very thing which it was proposed to do, and which had been done in other States, and which it was very necessary to do in New York, the medical society of that State amended the rules of conduct so that it or its members might, at discretion, enter into professional relations with any or all persons whom the law of the State at that time recognized to be practitioners of medicine. When this action was brought to the attention of this national body it resulted, not as might have been expected, in the amendment or the abrogation of the rule which had grown obsolete in the march

of events, but in its tacit reaffirmation and in the opprobrious excommunication, for the time being, of the entire profession of the great Empire State. This action, viewed impartially after the lapse of nearly twenty years, becomes the more extraordinary when it is observed that similar action was never taken with regard to Massachusetts or Rhode Island or Mississippi, the societies of neither of which had ever adopted the prescribed rules of conduct; nor with regard to California or Illinois or Colorado, each of which had, by overt act, if not by open declaration, so far as this rule is concerned, taken an equally non-conformist position. It is not surprising that, with such an example before the State societies, the experiment in consistency has not been repeated. But the movement of effective regulative legislation, once inaugurated, happily spread with great rapidity. Mixed boards of licensure are now to be found in the majority of the States of the Union, and in the majority of such boards are to be found members of the American Medical Association engaged in issuing licenses to practitioners of exclusive dogmas, and sitting in consultation with sectarian physicians, not over a dose of medicine, but over the vastly more vital question of the qualifications of those who are to care for the sick of our republic.

The Medical Profession and Society at the Beginning of the Twentieth Century.—The results of the twenty-five years of statutory regulation of medical practice are in striking contrast with the results of the quarter of a century of attempted regulations by methods of proscription. At the conclusion of that humiliating experiment, as at the beginning of it, there was not a single effective medical practice law on the statute books of a single State of the Union. To-day there are forty-eight State or Territorial licensing boards, the most of them being composed of representatives of both the regular and the sectarian schools of practice. The laws of the different States are of varying efficiency, the one procured by the Medical Society of the State of New York, at the price of yet-maintained excommunication from this body, standing to-day as the model of excellence for the entire country. Under the influence of these laws, instigated by members of the American Medical Association, and which, after all, are but expressions of the sentiments of the medical profession confirmed by society at large, many substantial reforms have been accomplished. The medical schools, which, in this country, have labored bravely and efficiently under adverse conditions, have been stimulated to increased efficiency. One of the first changes accomplished was the practical standardization of requirements to enter practice; and one of the first features of this standardization was to secure for the student "the aids actually furnished by anatomy, physiology, pathology, and organic chemistry"—the four cardinal studies which, strange-sounding as it seems, it was necessary solemnly and specifically to insist upon a half-century ago. It follows, therefore, that with broadened and increasingly uniform curricula, it cannot be said that schools even of sectarian antecedents entirely "reject the accumulated experience of the profession," nor can it be said that, in a sectarian sense, they any longer possess an excuse for existence. Their graduates, or such of them as do not base practice on an exclusive dogma, are, in many instances, met in formal consultation by even conservative regular physicians, and, in more than one instance, are made members of medical societies that are in affiliation with the American Medical Association.

The Illinois State Medical Society, which has always been among the foremost in reform movements within the profession, at its recent annual session unanimously—

"*Resolved*, That the school of graduation shall be no bar to membership in the Illinois State Medical Society, providing such physician is recognized by the local societies as qualified and not claiming to practise any exclusive system of medicine."

The Ohio State Medical Society, by precedent, if not by formal action, established the same rule.

We thus see that the proscriptive rule which, during the more than twenty-five years of its dominance, propagated the very evils it was intended to correct, is rapidly expiring by limitation in the face of new conditions that have been induced, in spite of it, by beneficent and catholic legislation. In the State of New York alone the annual registration of sectarian physicians has diminished nearly ninety per cent. under the operation of its present laws. In the State of Ohio many physicians who are graduates of sectarian schools are making application to have their classification on the register changed to "regular," while equal reactionary movements are observable in other States. Thus we observe the passing of Homœopathy and Eclecticism just as did the calm scientists of Rome witness the passing of the "Humoralism," the "Methodism," the "Eclecticism," and the "Pneumatic School" of that period; and just as passed the "Chemicalism," the "Iatro-Physical School," the Iatro-Chemical School," and the "Brunonianism" and the dozen other "isms" of later epochs, each leaving its little modicum of truth as the memento of its existence. And let us felicitate ourselves that, with the passing of the particular sectarianism of the last century, there is also the passing of its concomitant evils, such as existed in even greater degree in the time of Galen, who "found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems," and, as if relating the effect of the cause, the historian continues, "the social status and the moral integrity of the physician degraded." The further results of this new order of things however, are observable, not alone in the modified curricula of the medical schools, but in the changed organic relations of the institutions themselves. Under the pressure of legal requirements the weight falls with almost fatal force upon the small, private, and poorly equipped institutions. These institutions, in the interest of self-preservation, and to protect the respectable alumni, are forced either to expand their enterprises or to seek relations with universities which are deeply founded in the community; or else actually to go out of existence. The majority of the schools seek connection with the universities, by which step alone they become logical objects for endowment, and it is to be hoped that this movement will continue until in this great country medical education shall be as firmly established as it is to-day in any of the transatlantic nations.

Another of the new conditions which have developed within the last quarter of a century, as the result of an increasing professional unity, is the efficient sanitary regulations, national, State, and municipal, that now afford protection to the people from diseases that were formerly devastating in their effects. It is not necessary in this audience to mention smallpox, cholera, typhoid fever, diphtheria, anthrax, leprosy, and the bubonic plague, each of which has been brought under relatively effective control, but I do feel that it is necessary to emphasize the fact that there are many unsolved problems relating to the prevention of disease that stand as a challenge to the industry, the ingenuity, and the courage of the profession. While these various changes have taken place, others of almost equal importance are observable in the relations of physicians to society. While the community, instigated by the medical profession, has given to that profession a legal status, definite and increasingly influential, and has given it certain prerogatives and certain exemptions,

it has, likewise, hedged it about with certain limitations and imposed upon it certain liabilities. There are numerous laws, both common and statutory—*lex non scripta* and *lex scripta*—that admonish the physician that his conduct carries with it a liability not defined by self-imposed rules, and the numerous courts of our land proclaim that there are tribunals "other than his own conscience to adjudge penalties for carelessness or neglect" on the part of the physician. So numerous, so unjust, and so disastrous are actions before such tribunals that they have caused the development of a new, legitimate, and beneficent enterprise, in the development of a company to insure physicians against malpractice. It may be true that in certain States and localities these laws are unjust, and that there is a grave error in their administration by judges created under our wretched elective system; but if so, the facts only emphasize anew the necessity for more complete organization of the profession and for the more active exertion of its influence upon elections.

The Reorganization of the Association.—This brings us again to a realization of the fact that the results that can be achieved only by the unification of our national profession cannot be attained under the present organization of our association. The disproportionately rapid growth of *The Journal* as compared with that of the association can have no other significance. The weakness of the committee on legislation at Washington was a question neither of personnel nor of industry, but arose purely from the fact that there was no efficient organization in the rank and file of the profession by which speedy and effective influence could be brought to bear upon members and senators. Equal difficulty has been encountered in several States where organization has been similarly defective. The demand for more effective organization of the association has come from all over the country and resulted in the adoption of a motion at Atlantic City authorizing the appointment of a committee of three to report a plan of reorganization at this session. Another motion was adopted authorizing the creation of a supplementary committee of one from each State and Territory, entitled a committee on organization, which has been filled by appointing for the most part the retiring presidents of State societies for the current year. The committee on reorganization, consising of Dr. J. N. McCormack, of Kentucky; Dr. George H. Simmons, of Illinois, and Dr. P. Maxwell Foshay, of Ohio, has given to the important question entrusted to it a most careful and painstaking consideration. It has laid before you the results of its deliberation. In doing so it has emphasized the principle that this association has its origin in the organized profession of the respective States. It emphasizes the fact that the delegate body should be so small that it can remain in prolonged session and give to various subjects under consideration that deliberate attention which has not been possible under the existing scheme of organization during the last forty years. It recognizes the paramount importance of the scientific feature of our work by relieving the general meetings and the sections alike of the troublesome details that now consume the limited and valuable time of the sessions. It remedies the glaring and serious defects in the present constitution. It prepares the association, by perfecting the organization, to meet important and pressing questions. These considerations, together with the fact that the existing constitutional provision relative to delay of action on pending amendments has been met by the appointment, a year ago, of a committee for the avowed and published purpose of reorganization, and by the action of the committee in laying the results of its work before every member of the association—I say these considerations, and these facts, prompt me to advise the adoption of the proposed constitution and by-laws in their entirety at the present annual session of the association.

The committee on reorganization, under the restrictions of the resolution creating it, has, very properly, left undisturbed the existing rules of conduct. These if construed to have a fundamental importance, and if vigorously enforced as they now stand, would disintegrate the association in a single day. This reason, and others already given, confirm me in the conviction that such rules should be either amended or abrogated, or, if reaffirmed, it should be by general resolution endorsing their underlying principles but disclaiming the present applicability of their details. There are, however, various views entertained upon this subject; and that the matter may be approached in a spirit of tolerance, may be discussed coolly and impartially, that a consensus may be reached, and that harmony may be attained, I recommend that the general questions of the revision of the rules of conduct be referred to a special committee on ethics, consising of three members, with instructions to report to the legislative body at the next annual session of the association.

The New School of Medicine.—The changes which I have advocated are essential for the attainment of the purposes of the association and for the fulfilment of the high destiny of our national profession. They are demanded by the changes that have taken place during the last fifty years. The legislative functions have passed from voluntary organizations to the Congress and the legislatures, where they belong; but it still devolves upon the profession in the organized capacity, to stimulate, to restrain, or otherwise to control the law-making power. The responsibility of the profession is increased, rather than diminished. Science has come to have a clearer meaning. He who now proclaims a dogma cries alone in the night, while the world sleeps. They who demand a creed may read its varying terms only in the progressive revelation of natural laws. Practice has changed. The depletions, the gross medications, the absurd attenuations, the ridiculous antimineralism have given way to a refined pharmacy and to a more rational therapy. Sacrificial surgery has yielded to the spirit of conservatism. Prevention is given precedence over cure. Education implies research and discovery, and all may delve. I proclaim, events proclaim, the existence of a new school of medicine. It is as distinct from the schools of fifty years ago as is the Christian dispensation from its Pagan antecedents. It is the product of convergent influences, of diverse antecedent origin. It acknowledges no distinctive title, it heralds no shibboleth. It is a school of human tolerance, of personal independence, of scientific honesty. It is the slave of neither prejudice nor preconception, and abandons the accepted truth of yesterday, if it be only the demonstrated error of to-day. It places no premium upon personal prerogative, and extends no recognition to individual authority. It makes no proclamation of completeness, no pretension to sufficiency. It recognizes that truth is undergoing progressive revelation, not ending to-day, but continuing through the ages. It yields its plaudits to achievement, and recognizes that he is the greatest among men who reveals the most of truth unto men. It greets as a friend him who thinks, though he think error, for, thinking, he may think truth and thereby add to the common fund. It heeds all things, examines all things, judges all things.

To you, the exponents of this new school, of this new generation, of this new century; to you, representatives of the democracy of science; to you, citizens of the republic of letters, I extend greetings; and here in our parliament assembled, here where our will is supreme, I this day invoke upon our deliberations the spirit of liberty, the spirit of courage, the spirit of progress, the spirit of truth.

INTERNAL MEDICINE IN THE NINETEENTH CENTURY.[1]

By N. S. DAVIS, Jr., M.D.

CHICAGO.

It is one of the duties of those who address you, as I do to-day, to review what has been newly discovered in the field of medicine or in some limited department of it. At this first meeting of the American Medical Association in the twentieth century, it seems most natural to review what has been accomplished in the last one hundred years. The time at my disposal is too brief to read to you a complete history of the achievements of this wonderful epoch, for more of genuine advancement has been made in medicine during it than during all the preceding centuries together. It is possible for me to point out only some of the reasons for the rapid development of medicine, to recall to your minds some of the most important discoveries and applications of them.

A century is not so long a time as we are apt to think. Our grandfathers were vigorous men, in the prime of life, when the nineteenth century was born. Yet changes so great that they seem miraculous have occurred since then. In 1800 this great country was a wilderness, unknown even to the inhabitants of the few straggling settlements upon the Atlantic coast. Our land contained no great cities. There was little travel from place to place. There were no steamboats nor railways; no telegraphs nor telephones. Information travelled slowly by packet ship, canal boat, and stage coach. The discovery of the wonderful properties of the *x*-ray could not then have been flashed over the world in a day and its genuineness and utility confirmed within a few weeks by experiments made simultaneously in all parts of the world, as did happen at the close of the century. To-day all civilized peoples are so united that knowledge has become the common property of them all. In former epochs geniuses delved alone, inspired only by their own enthusiasm. Often it was many years before their discoveries became widely known or appreciated; and many more before another genius standing upon land already found ventured upon its exploration.

All this has been changed. Learning is not possessed by a few but by many. In earlier epochs men of genius towered above their contemporaries in learning. To-day thousands crowd about their shoulders, so much higher is the average of learning. All scientific workers are now linked together by the rapid dissemination of news, so that, no matter in what part of the world they may be, they are kept conversant with what is being thought and done in every other part, and they are thereby inspired to greater mental efforts.

Knowledge is no longer isolated. It is cultivated in centres too numerous to count. Even in this new land universities with great libraries, finely equipped laboratories, and corps of brilliant teachers and seekers after new knowledge, are found in every part of it. Medical societies have been organized in every State and city, and in many counties and towns. But at the beginning of the century there were only four medical schools in this country, and four State societies, organized for the advancement of medical knowledge.[2]

These changes have been effected chiefly by the rapidity of communication which has been established in all civilized lands, and by the greater concentration of the people in large cities.

But it is not in the United States only that the population has increased and concentrated. In 1801 the total population of England and Wales was less than nine millions. Of this number more than half lived in the country. At the end of the nineteenth century the population of the same countries was more than twenty-nine millions, and only one-fifth of this number lived in rural districts. These figures attract our attention to the social changes which have occurred in all civilized lands—changes which have effected not only a greater diffusion of knowledge, but have also modified the conditions which produce and limit disease.

At the opening of the nineteenth century, Cullen's "Practice of Physic," written late in the preceding century, was the standard text-book. A glance at its contents will give us the clearest conception of the state of medical knowledge at that time. In an edition of this work printed in New York City in 1806 I find no description of structural diseases of the heart; even as a complication of rheumatism heart disease is not mentioned. A single page is devoted to nephritis, but in its description there is no mention of the chemical and microscopical changes in the urine upon which we depend to recognize it and to distinguish its forms. The affections of the respiratory organs were described with similar crudeness, under such chapter headings as "Of Catarrh," "Asthma," "Pneumonic Inflammation," "Peripneumonia Notha," and "Phthisis Pulmonalis," but the catarrhal inflammations of the nose, pharynx, trachea, and bronchi were not differentiated from one another, nor were catarrhal and croupous pneumonia, brown induration, hypostatic congestion, and œdema of the lungs described.

The hypothetical explanation of diseases and their causes which prevailed at that time is well illustrated by the conclusion reached by Noah Webster, who, in his "History of Epidemics and Pestilential Diseases," writes that typhus and nervous fever are due to "conversion of the perspirable fluids of the body into septic matter."

Nothing will help so much to make clear the progress made in medicine in the last century as to compare the resources at the disposal of physicians of our day with those commanded by our grandparents. At the opening of the nineteenth century medical men knew nothing of the clinical thermometer, of percussion, auscultation, uranalysis, clinical microscopy, laryngoscopy, ophthalmoscopy, of the sphygmograph, or Roentgen rays.

It was not until the year 1808 that Corvisart spread widely a knowledge of percussion as a means of discovering the physical status of the viscera, although the work of Avenbrugger which he translated, and which was the original description of percussion, had been published nearly fifty years before. The work of Avenbrugger and Corvisart was supplemented in 1819, when Laennec published the result of his labor with the stethoscope which he invented four years earlier. From this time dates our clinical knowledge of diseases of the lungs and heart.

In 1827 Bright pointed out the relationship of albuminuria, dropsy, and diseases of the kidneys. At this point clinical chemistry may be said to begin.

At the beginning of the nineteenth century compound microscopes were almost useless, for the images which their lenses made were so distorted and colored that they could not be properly interpreted. In 1812 Dr. William Hyde Wolleston combined two plano-convex lenses so as to correct the spherical aberration which a single double-convex lens produces; and nearly twenty years later Joseph Jackson Lister discovered the utility of combining lenses of crown and flint glass in order to produce an image in the microscope relatively free from distortions and fringes of

[1] Annual oration in medicine, delivered at the fifty-second annual meeting of the American Medical Association, held at St. Paul, Minn., June 4–7, 1901.

[2] The colleges were medical departments of Pennsylvania, Columbia, Harvard, and Dartmouth (founded 1797). The societies were New Jersey (1766), Massachusetts (1781), Connecticut, and New Hampshire (1791).

color. The more recent invention of the oil immersion lens has made bacteriology possible, and has solved many of the problems of infectious diseases which puzzled even our fathers in the fifties and sixties.

The dependence of medicine upon ancillary sciences is well illustrated by the sudden birth and rapid development of new branches of medical knowledge which are dependent on the perfection of the microscope.

This instrument has made histology, embryology, modern pathology, and bacteriology a possibility. These departments of science are altogether products of the last century.

It was at the beginning of the century that Bichot divided the structures of the body into what he called "tissues," and showed that there were only a few of them. It is surprising that the great anatomists before him did not make the same discovery.

As modern anatomy has been dependent upon the microscope in order to explain structures, so physiology has been dependent upon experiments on living animals to explain function. It is true that in earlier epochs at considerable intervals of time experiments upon living animals were made, notably by Harvey, when he studied the circulation of the blood, but they were never made systematically until the discovery of anæsthesia in the nineteenth century made them painless. No wonder, therefore, that the explanations made by physiologists in 1800 seem to us extremely crude. Haller, for instance, whose printed lectures formed the text-book of most students at that time, thus describes the nature of blood: "Hydrostatical experiments demonstrate in the blood first a kind of volatile vapor or exhalation which immediately and continually flies off from the warm juice with a sort of fetid odor coming betwixt that of sweat and urine. This vapor, being catched and condensed in proper vessels, appears of a watery nature joined with a small tincture of an alcaline disposition."

A few pages further on what he says of the blood gives us an idea both of the state of physiological and pathological knowledge at that time: "For the blood in a sound healthy state, not injured by putrefaction or too violent a degree of heat, is neither alcaline nor acid, but mild and gelatinous and a little saltish to the taste; yet in some diseases it is sharp enough and comes near to a state of putrefaction, as, for instance, in the scurvy, when it corrodes through its containing vessels, and in those who have ascites or dropsy whose waters are often much of an alcaline and corroding nature."

At the close of the eighteenth century the part which gland cells play in forming secretions was not comprehended. It was believed that "the albuminous or hardening juices are separated almost anywhere from the arteries themselves, into continuous excretory canals, with any intermediate organ or machine betwixt them." It was believed that all excretions existed primarily in the blood.

The physiologists of this period appreciated the importance of the lungs and the act of respiration, but their exact use they did not comprehend. Haller enumerates several possible functions which they might perform, yet he did not feel sure that any one of them were the real ones. For instance, he says: "Our blood acquires its heat principally in the lungs, for that all animals which have lungs and two ventricles in the heart have the heat of their blood commonly twice that of the atmosphere. But does not this arise from the alternate extension and contraction, relaxation and compression of the pulmonary vessels by which the solid parts of the blood are perpetually rubbed together and closely compressed in the attrition that is made during expiration, as it is more rapidly moved and ground together during inspiration?"

Our forefathers one hundred years ago often endeavored to hide their ignorance in long names and resounding phrases, a common practice, indeed, in all times, and not wanting to-day, for how much ignorance will our successors find hidden in words now so commonly used as are metabolism and auto-intoxication?

Pathology as a distinct department of scientific medicine originated in the nineteenth century. It was not until 1860 that Rudolf Virchow demonstrated conclusively his famous dictum: "*Omnis cellula e cellula.*" His studies of cells in disease laid the foundation and did much to rear the superstructure of cellular pathology. So rapidly has a knowledge of this subject grown that we can unhesitatingly say that we now possess very accurate and detailed information as to the anatomical changes which disease effects. The insight of physicians was so greatly extended into the nature of morbid processes by these pathological studies that enthusiastic devotees of them felt that the application of the microscope to the study of disease would dispel its mysteries. Increasing information, however, soon demonstrated the limitations which exist as to knowledge derivable from a study of morbid anatomy. Most of us remember how, soon after the birth of bacteriology, it was also hoped that from it at least we would learn the true essence of disease. But we know now that in most ailments after the bacteriologist has discovered the offending micro-organism the chemist must help us, for it is usually a product of its growth, not its physical presence in the tissues, that causes disease.

The production of disease by parasites embedded in the tissues of the human body was suspected from early times, but was not demonstrated until the end of the first third of the nineteenth century, when James Paget, then a medical student, found unusual nodules in the muscles of a man whom he was dissecting. These Richard Owen demonstrated to be the cocoon of a minute animal which he called trichina spiralis. In 1847 Dr. Joseph Leidy, of Philadelphia, found them also in pork, and soon thereafter it was shown in Germany that men could become infected by eating pork containing trichina, and that in consequence there developed in them a definite train of symptoms.

In 1837 Latour in France and Schwann in Germany almost simultaneously propounded the view that fermentation and putrefaction are due to the growth of micro-organisms. Liebig, with all the weight of his authority, antagonized this belief in a "vitalistic" explanation of these phenomena. Pasteur undertook to settle the dispute by methods of research, which proved to be the foundation of a new department of science—bacteriology. The results of his experiments were published between 1857 and 1869. He proved that without micro-organisms there could be no fermentation, no putrefaction or decay. These studies prompted many investigators to attempt to demonstrate the suspected relationship of micro-organisms to disease. In 1863 Devaine succeeded in showing that the organisms, seen by him in 1850 in the blood of animals which had died of anthrax, were its cause. This, as some of those before me will remember, aroused a storm of controversy which was not settled finally until after my own student days.

Formerly, such vague terms as "miasm," "humor," and "virus" were used to explain the communicability of contagious diseases, but they have had to be discarded or to be newly defined by the bacteriologist. It was in the sixties that Lister made his studies upon the relationship of micro-organisms to wound infection. The brilliant, revolutionary results of those studies are too well known to you to require elaboration; besides they belong to the history of the nineteenth-century surgery rather than to the history of internal medicine. They were, however, so important

in settling the relationship of invisible parasites and diseases that they must be mentioned.

It was at this time, too, that Pasteur and Tyndall finally settled the controversy over spontaneous generation which had raged from time immemorial. The world at last felt convinced that even micro-organisms could not exist where an antecedent organism had not been.

It is needless to recapitulate the long list of discoveries rapidly made from this time onward of the causes of infectious diseases, by such men as Koch, Klebs, Loeffler, Fraenkel, Laveran, and many others.

Although medical men have been incited to search for the causes of disease in order that they might understand their nature better and therefore be able to treat them better, such studies naturally led more directly to the prevention than to the cure of disease. That is why the recent epoch-making bacteriological discoveries have greatly stimulated the study of preventive medicine. It is true that the prevention of disease has engaged the attention of medical men and statesmen since the earliest times, but the subject was not studied systematically before the last century.

Hygiene as a separate department of medicine, with a literature of its own, was created only in the nineteenth century.

While, in the eighteenth century, much was done to improve the hygienic state of individuals, and as a result there began before its close to be a reduction in the mortality rate, which has continued up to the present time, public hygiene or attempts to prevent the spread of disease by state and civic interference was not fairly established until very recently. Even to-day small communities have no health officers or sanitary inspectors, and few regulations which are intended either to inform the people as to the relative healthfulness of towns and hamlets or by which the spread of disease is to be lessened. These facts show how new and undeveloped as yet the field of public hygiene is. The mortality statistics which have been gathered in cities since the middle of the last century make it possible to point out which among them are the healthiest, and which diseases are the most destructive. It is to be hoped that these statistics in the future will be supplemented by reports of the kinds and amount of illness, whether fatal or not, that may exist in a given place.

The knowledge recently acquired of infections and their spread has already been applied to their prevention. Such diseases as erysipelas, septicæmia, and tetanus no longer torment surgeons when they can make clean wounds. But as late as 1870 the first of these ailments was common in the hospitals of France. Puerperal fever is to-day as rare as it was common formerly. Typhus fever no longer exists in America, although not uncommon at the beginning of the last century.[1] Indeed, it is rarely seen in any civilized country to-day. At the beginning of the nineteenth century smallpox was so common that few persons reached adult life without having had the disease, and the mortality from it in childhood was great. What is the status of this disease to-day? I venture to say there are many physicians in this audience who have never seen a case, and that a majority of them have not treated more than four or five cases during their whole professional experience. In the early days of this nation's history yellow fever spread to Philadelphia and New York, and provoked much discussion, for it was feared that it would prove as great a pest as cholera. A careful study of the disease and a consideration of the possibility of preventing it was referred to a committee of the New York Medical Society, which reported that yellow fever may be produced in any country by pestilential effluvia. How different is this conclusion from that of recent students of the subject, who assign to it a specific cause, which is transmitted from man to man by mosquitos, which are its host.

Cholera has been brought to our shores several times in the last few years, but its spread has been prevented in each case. In Europe it has also been limited to comparatively small areas. Within a year the plague has been found in this country, in Great Britain, and France, but has caused little alarm, so great is the confidence that it will be successfully suppressed. (Let us hope that this confidence is not misplaced.)

What has been accomplished during the last one hundred years by internal medicine the following statistics will show in part, although it must be remembered that mortality statistics gathered before the middle of the century are not reliable. It is estimated that in 1805 in New York City from 35 to 40 deaths occurred in every 1,000 inhabitants. During the last decade it has averaged 20 in 1,000, and has been as low as 19 in 1,000. In 1847 the mortality in London from zymotic diseases was 23.26 per cent.; during the last two decades 19 to 20 per cent. In 1846 the deaths from consumption were 12.67 per cent.; now approximately 9 per cent. The mortality from diseases of the respiratory organs has been reduced in the same time from more than 12 per cent. to about 7, and the mortality from diseases of the digestive organs has diminished from about 6 per cent. to less than 5. In Chicago the mortality rate has fallen, with small fluctuations, from 46 and 64 deaths per 1,000 inhabitants in the cholera years of 1852 and 1854 to 14 in 1898. The following diseases are among those in which the death rate has fallen progressively: Cholera infantum, croup, diarrhœa, diphtheria, dysentery, malaria, measles, scarlet fever, and whooping-cough. These are ailments the spread of which has been controlled either by isolation or by insuring the people purer food and water. Although the general mortality of Chicago, which is typical of the great cities of civilized countries, has improved, there are some diseases which are increasing in prevalence, notably nervous diseases, heart diseases, cancer, Bright's disease, bronchitis, and pneumonia. To the discredit of my native city must it be said that the mortality from typhoid fever reached its highest point at the close of the century, during 1890, '91, and '92, although its cause and its mode of dissemination, as well as its prevention, were well known.

The general lowering of the death rate is due to the improved hygiene of communities. In what the improvement has consisted is best shown by recalling some of the conditions under which people lived in 1800. At that time few cities had an adequate public water supply. In London water could be delivered at any house three times a week by one of the water companies; but most households depended upon wells. The sewerage system was quite as imperfect. Outhouses and cesspools were attached to each dwelling. The conveyance of sewage from houses by water did not become general until well into the last century. Ventilation of buildings, and especially of public halls, had attracted attention before the nineteenth century; but the real causes of danger from bad ventilation were not appreciated until bacteriology disclosed them.

In 1800 streets were not paved, and rarely cleaned. The habits of the people as regards eating and drinking were bestial. Excessively large quantities of food were consumed by all who could provide it. Alcoholic beverages were universally drunk, and generally in

[1] Typhus forms an item in the mortality reports of Chicago (and other American cities) as late as 1886. This is probably because it was confused with typhoid. Not during the first quarter and rarely afterward genuine typhus occurred in this country.

immoderate quantities. No disgrace attached to drunkenness; and it was customary for a man to drink several bottles of wine at a sitting.

Those who compose this audience appreciate how much illness must have been caused by these habits, and how much the relative abstemiousness or temperance of to-day has lessened the percentage of disease.

Prevention of diseases is possible only when a knowledge of their causes, their mode of dissemination, and methods for their suppression is possessed by all the people. Medical men alone cannot stop their spread, nor will the making of laws do it. Only the intelligent co-operation of those who are ill and those who are well can accomplish it. It must not be expected, therefore, that as soon as the cause of a disease is discovered, that ailment can be suppressed. Time is required in which to educate all classes of people on that particular subject. Unfortunately, many persons are so obtuse that they will not believe in methods of prevention even when the fullest demonstration of their success has been made. A notable instance of this is seen in the recent repeal of laws in England which made vaccination compulsory. The ease with which drinking-water may be become contaminated and the danger to health from contamination is not even now appreciated by the public. It is partly because such thorough knowledge is needed by the laymen that tuberculosis, diphtheria, pneumonia, typhoid fever, and similar troubles have not been better controlled in the past. In order that in the twentieth century the fruits of the great discoveries of the last may be gathered, all members of the medical profession must fit themselves to teach their patients what is known of disease and its prevention. Those who are especially adapted to do so must disseminate their knowledge by popular discourses and essays. When hygiene shall be regarded by all classes as necessary and as much a matter of course as the use of the railroad, steamboat, the telegraph, telephone, and labor-saving machines, then, but not until then, striking results may be expected.

The wonderful, the revolutionary discoveries made by students of internal medicine during the nineteenth century are not always appreciated as they should be, for their results are often demonstrable only by statistics; and the dramatic rescue of individuals from certain death which the surgeon at times accomplishes, unfortunately cannot be effected by the therapeutist. It is not in the nature of his art. Great progress, however, has been made in the use of medicines and remedial procedures. Good reasons can be given for their employment, and their mode of action can be explained. Empiricism no longer governs their use as it formerly did. The placing of therapeutics upon a scientific basis began in the last century when the physiological effect of drugs was first demonstrated by experiments upon animals.

No field of medical research needs cultivation so much or is more certain to yield a rich harvest than therapeutics. It is surprising that we have not a larger volume of accurate knowledge of the effect of drugs than we do possess. Of late pharmacology has been neglected for studies which have temporarily been more enticing to experimenters, such as bacteriology and experimental pathology. Moreover, a knowledge of these subjects is essential to enable a clinician to apply his therapeutic resources to the mitigation of suffering, the support of strength, and the elimination or destruction of noxious substances. One can safely prophesy that the exact utility and the limitations of drugs and medical procedures will be defined in the present century.

To accomplish this, not only is more knowledge required of the physiological action of drugs, but also better means of accurately measuring their effects when they are given to patients. We know when pain is relieved, we can sometimes measure effects produced upon the heart and blood-vessels and temperature. Beyond this we depend for knowledge upon the impressions of physicians, impressions which must be corrected and often reversed by a wide experience. Clinicians possess only a few appliances or methods for the exact study of the sick. It is to be hoped that more will be discovered, and that they will also make it possible to register with accuracy the effect of drugs. When this is accomplished, undoubtedly a smaller number of useful drugs will be employed, but these with greater exactness.

It is true that more drugs are used to-day than need be, because patients demand them as a fetish; but this will be changed when laymen learn that it is the function of the physician to teach them what to do to give nature the best chance to effect repair, what to do to make themselves comfortable and to preserve life; when they learn that it is a physician's function to teach them how to protect others from the same ailment, to foretell the possibility of recovery or death, and to avert or forestall complications. Medical men should include time and faith in their materia medica as important means of effecting a restoration of health. I do not mean faith in a fetish procured in an apothecary's shop, but faith in the wisdom, honesty, and disinterested devotion of physicians which will enable them to accomplish all that can be done for the suffering.

Although the greatest discoveries in the field of internal medicine have been applicable to the prevention of illness in the masses, much has also been done to increase the chances of recovery of individuals who are sick. I need call attention only to a few of the improvements in treatment which have been effected to remind you of more. Typhoid fever, which has been a scourge in all civilized countries, and constantly present in all large centres of population, has not only been greatly lessened, sometimes even suppressed by improved hygiene, but the chances of recovery of the one who is sick with it have been increased several fold by improved methods of treatment. Twenty-five years ago the mortality from typhoid fever in the hospitals of the world was from twenty to thirty-five per cent.; to-day it is from five to fifteen. The better results are due to the cold baths which are used, to a more generous supply of fresh air, to proper feeding, and to protection against or the prompt treatment of complications.

One great therapeutic discovery has been made at the end of the nineteenth century—the discovery of antitoxins, the natural antidotes to the poisons of infectious agents. For a very long time it had been known that something developed in the human system during the course of many ailments which gave to the sufferer from them for a variable time immunity from a recurrence of the same disease. Until the existence of parasites and of poisons generated by them was proven, an antitoxin was of course unrecognizable. Moreover, the possibility of such a thing in diseases, one attack of which did not cause immunity to others, was not even suspected. But the diphtheria antitoxin, the most efficient of those of which we know anything, is one belonging to this last group of ailments. The chemical composition of antitoxins is yet to be discovered. Since antitoxin has been used the mortality from diphtheria has been reduced about one-half. The most extensive collection[1] of statistics gathered from all civilized countries shows that when antitoxin is used on the first day of the disease, the mortality is five per cent., increasing rapidly to thirty per cent. when used on the fourth day or later. Before its employment, the average mortality of the disease was

[1] Das Oesterreichische Sanitätswesen, No. 52, 1900.

from twenty-five to thirty-five per cent. To effect a still greater reduction in the death rate from this ailment, it is necessary that it be recognized early, and that antitoxin be employed more generally as a preventive for those who have been exposed.

That tetanus antitoxin and plague antitoxin are valuable is admitted. Many others, such as pneumonia, typhoid, tubercle, scarlet fever, erysipelas, and streptococcus antitoxins are still in the experimental stage. But even though it should be found that few natural antitoxins can be isolated for use as remedies, those already discovered confirm physicians in the hope that specifics will be found some day.

Another therapeutic discovery made at the close of the century which has thrown a flood of light upon some obscure points in physiology and pathology, and has restored to usefulness many who were formerly incapacitated and incurable, is that of internal secretions, and especially the rôle of the secretion of the thyroid gland. Ingredients in the thyroid, suprarenal bodies, and ovaries produce as definite effects upon the living body as many extracts from plants or synthetic chemicals. The pituitary body, the thymus, and bone marrow may also have a value as yet undetermined. The rescue of those suffering from myxœdema and cretinism by the administration of thyroid is one of the few happy dramatic incidents which fall to the lot of the practitioner of medicine.

That a much larger proportion of recoveries from tuberculosis occur to-day than formerly is evident from the statistics of this disease, but this lessened mortality is not due to prevention only. Trudeau has estimated that eighteen per cent. of all persons have tuberculous lesions, because a reaction to tuberculin can be demonstrated in that proportion. This statement is confirmed by Councilman, who states that his autopsy statistics show that at least seventeen per cent. of all who die have had this disease. But in spite of this prevalence the mortality from the ailment is lessening.

Rabies and tetanus are two diseases which until recently were thought to be incurable. Rabies can be suppressed by killing unowned dogs and by muzzling the rest. Upon this point the following statistics from England are very instructive: In 1887, 217 deaths occurred in Great Britain from rabies; in 1888, 160; in 1889, 312. A muzzling law was then enforced. In 1891 the death rate from the disease fell to 129; in 1892, to 38. The muzzling ordinance was repealed, with the result that in 1894 248 deaths occurred from mad-dog bites, and 672 in 1895. Again muzzling was made compulsory. The death rate once more diminished; in 1897 it was 151; in 1898, 17; in 1899, 9, and in 1900, none.

Pasteur's great discovery of a method of attenuating the virus of rabies and rendering those who have been bitten by mad dogs immune by rapidly accustoming them to stronger and stronger viruses, has markedly reduced the mortality.

Tetanus, quite common in hospitals formerly, is now prevented by proper cleansing and protection of wounds. It has become so rare a disease that to-day most students do not see a case of it during their college course.

The nineteenth century will be known in the history of medicine as the century of experimental medicine, for it is in that field that the greatest discoveries of the age have been made. The names of Pasteur, Koch, and Lister will forever be linked with it as representing its greatest achievements. But these achievements would not have been possible had not the physicist perfected the microscope, and had not Virchow and his pupils explored the field of cellular pathology to its farthest limits. Around Virchow's name as a banner will historians gather the achievements in medicine during the early and middle portions of the century, and around Pasteur's those of its close.

If our greatest needs conditioned the growth of knowledge, we could prophesy what will be the great field of research of the twentieth century, but history teaches us that our needs can often not be met until some sister science has grown, or new methods of experimenting have been devised. Therefore, the future must remain a blank to us. However, we are more apt to accomplish what is needed if the problems are kept clearly in mind. We greatly need more exact methods of clinical study, more accurate knowledge of the effect of remedial agents and procedures, but more than all else we need a knowledge of the changes which take place in the living tissue in health as well as in disease.

The anatomist has resolved the cellular structure of the body; the physiologist, the laws which govern the action of its organs and the chemical changes which are wrought upon its surfaces; the bacteriologist has discovered the parasites that infest, and often destroy it; the pathologist has described the anatomical changes which disease produces; the clinician has linked all these facts together and has discovered ways of seeing with the intellectual eye disturbances of physiological function, of determining their cause, and of anticipating the anatomical changes which they will produce. But this does not satisfy us; we want a knowledge of the atomic and molecular structure of cells, of the changes which take place in the atoms and molecules in health and in disease, and of the effect of medicines and remedial procedures upon them. This knowledge chemistry must give us. I feel sure that, standing as we do at the beginning of a new century, expecting greater developments in it than in the last one, we are halting before new discoveries in chemistry, waiting for new methods of studying metabolism in microscopic portions of tissue. When this knowledge is vouchsafed, medicine will make another stride as great as was made when, by the perfected microscope, cellular pathology and bacteriology became possible.

Let us look forward with confidence to the Virchow and the Pasteur of the future.

THE VALUE OF CLINICAL MICROSCOPY, BACTERIOLOGY, AND CHEMISTRY IN SURGICAL PRACTICE.[1]

By JOHN A. WYETH, M.D.,

NEW YORK.

For many years, almost without exception, my predecessors in the address on surgery have devoted their labors to the exposition of some general or special subject in the domain of operative surgery, and while I would in no measure detract from the value of a thorough technical knowledge, we should not, in our attention to the art, fall short of a proper appreciation of the science of surgery.

The experienced surgeon soon learns that it requires more than asepsis and the rapid and skilful performance of an operation to achieve the fullest measure of success; that although a thorough practical knowledge of regional anatomy is essential in the highest degree to the conscientious fulfilment of the professional obligation, it is equally important that there be called into requisition the invaluable aid which laboratory research alone can give in determining an accurate diagnosis; in indicating the most rational measures

[1] Oration on surgery before the fifty-second annual meeting of the American Medical Association at St. Paul, Minn., June 4–7, 1901.

of treatment not only in the preparation of a patient for an operation, and in the selection of the safest anæsthetic, but for the post-operative management of the case, and in removing as far as possible all doubts as to the prognosis.

Chemical analysis of the normal and abnormal secretions and excretions of the body, clinical microscopy and bacteriology should form a part of the educational requirement of every surgeon. I do not insist that the busy practitioner should attempt to master all the intricate processes of the laboratory, for this is possible only to one who devotes years of patient labor in the fascinating department of science, but he should possess that practical knowledge of the chemistry of the body in health and disease, and of clinical microscopy and bacteriology which any diligent student, under a competent teacher and in a properly equipped laboratory, should be able to acquire in a three months' course of study.

The instances are exceptional in practice in which this knowledge cannot be applied with great benefit to the patient and with satisfaction to the surgeon. It is naturally of greatest value in the cases in which no emergency for immediate operation exists, but its advantages are not wanting in these rarer cases, since it comes to his aid in the post-operative period.

Laboratory research, especially in the department of bacteriology, has placed not only the medical profession but the entire human family under lasting obligations for the great benefits which have already been derived from its discoveries, and it may be safely said that it has done more than all else in accomplishing the revolution in surgical thought and practice which has taken place within the last two decades. One of the most notable illustrations of this great advance is the triumph which has been achieved over that once fatal disease, diphtheria.

The discovery by Klebs in 1883, and the isolation and cultivation in 1884 by Loeffler of the bacillus of diphtheria had its logical sequence in Behring's invaluable discovery (subsequently elaborated by Roux) that the blood of animals, especially that of the horse, rendered immune to diphtheria by inoculation, first with attenuated, and then with more virulent organisms, contained a substance capable of neutralizing the effects of the bacilli or their toxin when simultaneously or subsequently inoculated in non-protected animals.

This antitoxin serum in its dose of 10 c.c. of either the 600, 1,000, or 1,500 immunizing units is potent not only to arrest the destructive processes which formerly characterized this disease, but to prevent the infection of those who have been exposed to the contagion. How great is the importance of the knowledge that these bacilli are not only always present in the throat of a patient suffering from diphtheria, but that they are frequently found on the nasopharyngeal surfaces and tonsils of persons free from systemic infection, and as shown by Biggs, Parke, and Beebe, of New York, they may remain as long as five weeks after the membrane has been discharged from infected subjects, all of which points to the necessity for the isolation of the infected individual, and the careful disinfection of the throats of those who have been about diphtheria cases (McFarland).

The statistics of Professor Welch, of Johns Hopkins University, show that the ratio of mortality as a result of these discoveries has been reduced more than fifty-five per cent., and that in one hundred and fifteen cases, in which by reason of an early diagnosis, the treatment of serum antitoxin was begun within the first three days of the disease, the mortality was only 8.5 per cent. In five hundred and forty-six cases in which the remedy was begun after the third day of the disease, the mortality was 27.8 per cent., the ratio of mortality increasing with fatal precision as treatment was delayed.

To the surgeon, one of the most gratifying results of this great triumph of the laboratory is the fact that he is now rarely called upon to perform the operation of tracheotomy, which was formerly distressingly frequent; nor to witness the sufferings associated with intubation of the larynx. A professional friend in the department of diseases of children informed me recently that whereas a few years ago he had from ten to twenty intubations of the larynx on account of diphtheria in every month, he now, since the serum therapy was practised, averaged only one or two.

I believe that what is true of this disease is true of all infectious processes, and that, as our knowledge expands, a safe immunizing serum will be discovered for each special toxæmia. Even now it would seem that this proposition is proved in other infections in which like diphtheria the pathogenic organisms are localized at the seat of infection, their toxic products alone entering the tissues through the circulation.

Of this type is the spirillum or "comma" bacillus discovered by Koch in 1884 in the intestinal contents of patients suffering from Asiatic cholera. These germs are not found in the deeper organs, the morbid changes in the tissues being due to their toxin. Immunizing injections of cholera cultures have already been experimentally and successfully employed, and promise rich results.

In this same group, bacteriologists claim a place for the diplococcus lanceolatus of Fraenkel, the pneumococcus. Sternberg and Pasteur isolated this germ in 1880, and in 1884 Fraenkel demonstrated it as the prevailing organism found in the sputum of croupous pneumonia. Very late investigations give encouragement to the hope that serum therapy will soon be applied in the early arrest of the invasion of this most painful and fatal malady. Though pneumonia is strictly a medical disease, its early recognition as a surgical complication, or in view of an anticipated operation, is of very great importance. In a recent case which came under my observation at our laboratory, a specimen of sputum was sent in for bacteriological study. It was not blood-stained or "brick-dust," but yellowish-white in color like the ordinary sputum of bronchitis, and was supposed to be "grippe," or tuberculosis. The bacillus of tuberculosis was not present, but numerous micrococci lanceolati were discovered, and the laboratory diagnosis was made and confirmed within twenty-four hours by the well-recognized symptoms of consolidation with the "brick-dust" expectoration of this disease which supervened.

Tetanus toxæmia, or "lockjaw," the organism producing which was discovered by Nicolaier in 1894, and which for years has baffled the most strenuous efforts of the bacteriologist and clinician, seems at last to be classified with the controllable infections. Professor Osler, in the last edition of his "Practice of Medicine," says the immunizing serum of Tizzoni has been successfully and encouragingly employed in doses of 2.25 gm. for the first dose, and 0.6 gm. for subsequent doses. Of one hundred and thirteen cases treated by this method sixty-three per cent. resulted in recovery.

It was not until the discovery of the bacillus of typhoid by Eberth in 1880 and the pure cultures of this germ secured by Gaffky in 1884, that there was made possible in the vast majority of cases of typhoid fever a positive diagnosis.

The demonstration of Widal that when ten drops of a twenty-four-hour bouillon culture of the bacilli typhi were added and thoroughly mixed with one or two drops of serum from the blood of a typhoid patient, the bacilli lose their motility and become agglutinated in masses, was one of the most brilliant advances in

clinical bacteriology, and of great value in surgical diagnosis.

In many of the lesions of the abdominal viscera, and especially in those located in that battle-ground of surgery, the right iliac fossa, where the physical signs and the febrile movement may suggest either beginning typhoid, intestinal toxæmia, or a pyogenic sepsis, an early diagnosis may be determined in no other way than by the aid of the laboratory.

The practitioner who has not called into requisition the invaluable aid which bacteriology affords in the differentiation of those too often obscure intraperitoneal lesions, cannot appreciate the satisfaction which this practical application affords. How often the safety of a patient hangs upon even a few hours' time, and alas, how often this precious time is wasted in the uncertainties of diagnosis, when a resort to the demonstration of science, available to all, would have plainly indicated the proper method of procedure. We know too well the fallacy of relying upon the ordinary subjective symptoms, and even some of the objective symptoms afford us no accurate clew to the pathological process which may exist. The pulse and the temperature of commencing typhoid may well be mistaken for the pulse and temperature of an appendicitis. The pain and muscular resistance over the right iliac and the right abdominal region are in many instances practically alike. The nausea, the vomiting, and the general sense of uneasiness point neither directly to the one nor to the other disease, but in a crucial test by Widal's reaction, with the blood count pointing to the presence or absence of a leucocytosis, the question is quickly settled. I have seen all the symptoms of appendicitis present in cases in which the blood count contradicted a pyogenic sepsis, and in which Widal's reaction told the story of typhoid. On the contrary, I have dealt with cases which ordinarily would have been most perplexing, in which all the symptoms of typhoid prevailed at a period when it was too early to recognize this disease by Widal's test, and a leucocytosis of from 15,000 to 21,000 proved at the earliest possible moment that the case was one for immediate operation.[1]

The discovery by Bollinger in 1877 made the diagnosis of that comparatively rare affection, actinomycosis, clear. In examining the yellow granules and accompanying pus discharged from an infected area he recognized the ray fungus or actinomyces. More recent researches have shown this fungus to be composed of bacilli in various stages of development, some being spores and some more perfectly developed organisms.

In another fortunately rare disease, malignant pustule, caused by the lodgment in an abrasion of the bacillus anthracis, we are indebted to the laboratory for our knowledge of its etiology. The anthrax bacillus discovered by Devaine in 1863 is not usually found in the blood except in the most malignant cases and in the last stages of fatal infection, but it can be demonstrated in the pustule of inoculation with the microscope or by cultures.

Roux and Chamberland, according to McFarland, have found that filtered cultures will produce immunity when properly introduced into animals, and we reasonably hope from these experiments that the serum treatment will before long be made applicable to infected human beings.

Another rare organism is the bacillus of malignant œdema, which was discovered by Pasteur in 1875 and called by him vibrion septique. There are only two cases of this disease so far reported in man, and they were subjects of abnormally low resistance infected by the hypodermatic administration of a product of musk.

The bacillus pestis or bubonic plague organism was discovered in 1894 simultaneously by Yersin and Kitasato, in blood drawn from the finger-tips of infected individuals, and in the broken-down lymph glands, and is described by Kitasato as greatly resembling the micro-organism of chicken cholera.

Bacteriological research has robbed the puerperal state of much of the anxiety and dread which formerly attended this ordeal, not only in preventing sepsis, but in recognizing the infections already established in time to prevent a general peritonitis or septicæmia. The puerperal uterus, or this organ when the seat of non-puerperal endometritis, offers an ideal field for bacterial proliferation and invasion, since septic organisms entering the cavity may rapidly penetrate the endometrium and enter the lymph channels whence they pass into the venous sinuses and lymphatics of the pelvis.

Prof. W. R. Pryor, in a paper read before the New York State Medical Association in 1900, says, "Puerperal sepsis if not rapidly fatal almost always produces lesions which seriously damage the pelvic organs or the viscera," and that "time is in this serious condition an important element." He recommends the early employment of the Döderlein tube, which, after sterilization, is passed into the uterus, being protected from contact until the fundus is reached. From the serum and débris thus obtained cultures are made, and the character of the operation—either curettage or hysterectomy—determined by the result of bacteriological investigation.

Not only does the laboratory come to our assistance in the diagnosis of certain obscure surgical lesions of the stomach, but it is still more valuable as an aid in arriving at the exact condition of the digestive functions of this organ, any derangement of which it is at times exceedingly important to correct in order to bring a patient into suitable condition to stand an operation. Thus it is important to determine in certain instances whether or not free hydrochloric acid exists in this organ, and while the total quantity poured into the stomach in the digestive process cannot be accurately measured, clinical chemistry can closely estimate the total quantity found at a given moment during digestion. The acid-combining power of the proteids is known, and by certain tests it is feasible to estimate, sufficiently close for a satisfactory diagnosis, the quantity of hydrochloric acid secreted.

[1] Two of the cases occurring in my own work within the last few months may emphasize the great value of this technique.

A man of thirty was seized with quite severe pains which were confined to the region of the cæcum and appendix. Upon palpation there was well-marked resistance in the muscles immediately over these organs which was not observed in any other part of the abdominal wall. He had vomited on one or two occasions, and the temperature ranged from 101° to 103° F. on the second day of this attack. The questions which were presented to the consultants were whether this temperature could be accounted for by intestinal toxæmia, by appendicitis, or incipient typhoid. Although it was too early in the history of a typhoid case to encourage the belief that Widal's reaction would be present, this was made, and with negative results. On the following day, the symptoms still pointing toward typhoid fever, a careful blood count was made and the leucocytes did not count over 7,000. Assured from this that no dangerous pyogenic process was present, the idea of operation, even exploratory, was abandoned until the examination might be repeated on the succeeding day. A second careful blood count showed no leucocytosis, and on the fourth day, although Widal's reaction was still absent, the case was declared to be typhoid, and the subsequent history proved the diagnosis to be correct, since a few days later the reaction of typhoid was present, and the patient went through the regular stages of this fever.

In a second case, a male patient, forty-five years of age, there was a typical typhoid tongue, temperature ranging from 100° to 103.5° F., tenderness and muscular resistance were present in the right iliac fossa, and loose discharges from the bowels not unlike those frequently met with in typhoid. Widal's reaction was tried with negative results on three successive days. The blood count on tha fifth day showed the leucocytes numbering 21,000, justifying e diagnosis which excluded typhoid and confirmed the suspicion of pyogenic sepsis.

The small quantity of hydrochloric acid which combines with ingested inorganic elements is lost to gastric digestion, serving as it does its function in this process in the intestines.

It is clear, as stated by Van Valzah and Nisbit, that the hydrochloric acid which combines with the proteids, and that which remains free, together roughly represent the activity of acid secretion. It is logical, then, to conclude that the quantity of hydrochloric acid loosely combined with albumin, together with the quantity remaining free in the contents withdrawn at the end of a particular time after the eating of a particular meal is a practical and clinical measure of the secretory activity of the peptic glands, and of the digestive work of the stomach. All of this is made sufficiently exact for practical purpose by the laboratory method of analysis after the simple test-breakfast of Ewald and Boas, or the more elaborate test-meal as recommended by Germain-Sée.[1]

The presence of lactic acid in the stomach contents as shown by Kelling's test[2] has a distinct diagnostic value, since it takes place in comparatively rare conditions, and since these conditions are seldom fulfilled except when carcinoma is present.

Lactic acid is dependent upon the presence of a special bacillus which thrives in the stomach under abnormal conditions, and is capable of converting glucose and lactose into lactic and carbonic acid. Boas goes so far as to insist that the persistent presence of lactic acid in noteworthy quantity during the digestion of a saucer of oatmeal, chemically free from lactic acid, is a specific sign of carcinoma of the stomach.

While the stomach may under varying conditions contain hosts of various bacteria in addition to the one just considered, there are only three others that are of importance as pathogenic organisms. First, the sarcinæ ventriculi (in their usual cube arrangement), which when found indicate insufficiency of the stomach muscle due to non-malignant obstruction. They are not found in carcinoma, since they perish in the presence of lactic acid, which, as we have just shown, is so common in malignant diseases of this organ.

[1] The simplest method is that known as the test breakfast of Ewald and Boas, in which on an empty stomach, usually in the early morning, a breakfast roll which contains about 5 gm. of proteids, 39 gm. of carbohydrates, ½ gm. of fat, ¾ gm. of ash, and weighs 70 gm., and 350 c.c. of water (about a glass and a half) are taken. The bread should be thoroughly chewed and insalivated before being swallowed with the water. Usually in one hour's time a tube is introduced and the contents of the stomach are withdrawn, usually by expression, or by siphonage, and then filtered. An estimate of the acidity of the filtered contents is made by the use of a decinormal solution of potash or soda. The number of cubic centimetres of this solution which will neutralize 100 c.c. of the filtered contents of the stomach expresses in figures the acidity of the fluid withdrawn. At the end of an hour, under approximately normal conditions of digestion, the total acidity should be 50 to 60, the hydrochloric-acid albumin 30 to 40, the free hydrochloric acid 10 to 20. Any departure from this rule shows the abnormal absence or excess of this important agent.

The test meal of Germain-Sée is at times preferable, since it contains a larger quantity of proteids than the test breakfast of Ewald and Boas just given, but the method of procedure is practically the same. The presence of hydrochloric acid can be recognized by Günzburg's reagent, which is composed of :

Phloroglucin	2 gm.
Vanillin	1 gm.
Alcohol (absolute)	30 gm.

By spreading three or four drops of this reagent in a porcelain crucible, adding upon this the same quantity of the filtered contents, and slowly warming the crucible, after several seconds a red color appears, and at times the red crystals of free hydrochloric acid are seen. Or the simpler method may be used of employing a filter paper which has been soaked in a 0.5-per-cent. alcoholic solution of diamethylamidoazo-benzol and dried. This in the presence of a trace of free hydrochloric acid turns distinctly red.

[2] Kelling's test consists of 5 c.c. of the filtrate diluted to 50 c.c. with distilled water, to which one or two drops of official five-per-cent. solution of the perchloride of iron are added. The yellowish-green tinge indicates the presence of lactic acid.

Another micro-organism is the yeast plant, also found when motor insufficiency exists. It may be present when the stomach contents are alkaline, neutral, or acid.

The bacillus geniculatus is present under the same conditions which produce the lactic-acid organism, and is considered also to be suggestive of carcinoma.

When the presence of blood is suspected in the stomach and is not clearly defined by the microscope, chemistry comes to our aid in its recognition by the glacial acetic acid and ether test.[1]

A study of the discharges from the rectum is as yet of little value to the surgeon. Beyond the recognition of blood or pus, or cast-off cell elements in certain malignant neoplasms, there is but a single organism which is of real diagnostic value, namely, the amœba of dysentery, described by Lamb in 1859, which is a motile mass of protoplasm about 20 μ in diameter, containing a single nucleus and one or several vacuoles.

In the differentiation between the pathogenic organisms of specific and non-specific urethritis, microscopy and bacteriology are our only infallible guides. They teach us to eliminate the various bacteria found in the external genital and urinary passages, not bearing directly upon the etiology of urethritis, and to recognize distinctly the two forms of diplococcus, the gonococcus of Neisser and the pseudo-diplococcus, which, while not morphologically different from the specific disease-producing organism, can be readily distinguished by special modes of staining as well as by cultures. In the daily routine of practice the exact nature of every suspicious urethral discharge should be subjected to careful scrutiny. The patient is entitled to the satisfaction of a negative result, which is easily demonstrated by staining the smear with methylene blue, which clearly defines both organisms. If no cocci are revealed, all anxiety is put at rest; but if there are present both varieties of these organisms, occupying as they do the protoplasm of the pus corpuscles, a further research and the differentiation of the true form from the false diplococcus are imperative. The pseudo-coccus retains the violet color of the aniline-gentian water violet stain, while with careful laboratory technique the addition of the Bismarck brown brings out the gonococcus, the protoplasm of a single pus corpuscle showing at times both the blue stain of the pseudo-coccus and the diplococcus of Neisser which retains the brown color.[2]

Bearing in mind the fact that the gonococcus of Neisser may remain dormant in these passages for

[1] To 10 c.c. of the filtered contents add 3 c.c. of glacial acetic acid, and extract the coloring matter of the blood by shaking with 5 c.c. of ether. This turns the ether extract brown. When this discoloration does not take place there is no blood. To carry the demonstration further, to the brownish decanted ether extract 10 drops of fresh tincture of guiac with a few drops of peroxide of hydrogen are added. After vigorous shaking, the mixture becomes clear blue if blood is present.

[2] Dr. Jeffreys, the director of the laboratory in the New York Polyclinic, employs the following differential stain :

Use Gram's stain followed by a contrast stain, such as Bismarck brown. To prepare this stain proceed as follows :

Prepare aniline water by emulsifying 8 drops of aniline oil in about 10 c.c. of water. Filter through a wet filter. To this aniline water add about one-tenth its bulk of a saturated alcoholic solution of gentian violet. Stain smear with this "aniline-water gentian violet" one or two minutes. Wash in warm water and then immerse in Gram's solution for one minute. The formula for this solution is as follows :

Iodine	1 gm.
Iodide of potassium	2 gm.
Water	300 c.c.

Thoroughly wash in ninety-five-per-cent. alcohol until no more blue appears to wash out; then wash in water. Counterstain for one minute with a saturated solution of Bismarck brown in three-per-cent. aqueous solution of carbolic acid. Wash, dry, and mount in balsam. After this treatment pseudo-gonococci should be stained violet, and gonococci should be brown.

months, and, as maintained by some observers, for years, incapable of a further inoculation of the seemingly immunized patient, but capable of exciting the most acute and injurious inflammation in an innocent victim, it becomes a matter of the greatest importance to subject to most careful study the external genito-urinary passages when an infection has once existed. It has been demonstrated that an artificial urethritis as that which nitrate of silver produces will develop the dormant gonococci and cause their presence in the discharge.

Keyes and Chetwood, in their excellent volume on venereal diseases, place well-deserved emphasis upon the value of the Gram test for recognizing these organisms. They properly insist that the diplococci should be of the recognized size and have within the protoplasm of the pus corpuscle their proper shape and arrangement and remain negative to Gram's staining. Even when cultures are made to demonstrate the specific organisms beyond all doubt, resort should still be had to the Gram staining as a final means of identification.

In cases of pyelitis, many of the difficulties which formerly stood in the way of differential diagnosis between renal calculi, simple pyogenic pyelitis, or the presence of tuberculous disease in this organ, are now overcome by the careful methods of the laboratory.

The presence of the bacilli of tuberculosis in one or both kidneys, even when they are exceedingly infrequent in the discharge, can be demonstrated in urine drawn by urethral catheterization, or by the more simple process of bladder segregation, when the suspected organisms are with other detritus thrown down by the centrifuge. The carbol-fuchsin stain decolorized with five-per-cent. sulphuric acid brings out in brilliant red the outlines of the bacilli of tuberculosis, while the addition of ninety-five-per-cent. alcohol decolorizes the smegma bacillus, and thus eliminates this possible source of error to any but the more expert laboratory workers.[1]

In the effort to arrive at the general condition of a patient, the chemical, microscopical, and bacteriological study of the urine is only second in importance to that of the blood, and when we consider the additional and exact information which can thus be obtained concerning any pathological process at any point in the urinary tract, the value of this analysis is very materially increased. A careful study of the urine is always indicated before we determine what anæsthetic it is safest to employ in the operation to be undertaken. When there is no important lesion of the heart, either in its valvular mechanism or in the blood supply and nutrition of its muscular walls, few surgeons, I hold, would employ ether in a protracted operation in which there was any suggestion of an acute nephritis, or in certain chronic forms of Bright's disease.

It is commendable practice to study through several days the quantity of urine passed, keeping accurate measurement, as well as making a qualitative analysis of that which is passed under conditions as near as possible similar to those to which the patient had been subjected before coming under observation, and then under conditions of rest, with proper alimentation and the free opening of the alimentary canal with calomel and Carlsbad salts (which agents in my experience most readily do away with fermentation and the production of gases in the bowels), to note the changes which occur in excretion.

The presence of oxaluria is in my opinion a contra-indication to a serious surgical operation, for the reason that it is pathognomonic of a disturbed nutrition due to insufficiency of the digestive fluids, and to fermentative processes in the intestinal tract.

An excess of uric acid, evident in the rosettes or rhombic or quadrate crystals (one-sixth objective) found in the urine which has not been passed more than three or four hours, has also a pathological significance scarcely less than that of oxaluria. It indicates a condition of defective nutrition which is part of the gouty or rheumatic diathesis, predisposes to chronic nephritis, and is one of the symptoms of various acute inflammatory processes, of leukæmia, cirrhosis of the liver, gastro-intestinal catarrh, and is often present in diabetes mellitus.

The chemistry and microscopy of the urine further inform us when ammoniacal decomposition of the urine is taking place within the bladder, suggesting insufficiency of this organ due to obstruction of the urethra or to atony of the bladder muscle. The large rhombic masses or stellate and cross-shaped rosettes of the triple phosphates exist only in these abnormal conditions of the bladder, and with the brownish colored, thorn-like crystals of urate of ammonia are important aids to diagnosis.

The presence of epithelia from the various portions of the urinary or genito-urinary tract, of spermatozoa and various bacteria chiefly pyogenic in character, are further and well-recognized evidence of the value of the microscope in surgical diagnosis. In rarer instances, the hooklets of echinococcus, the embryos of filaria, and the ova of hæmotobium Bilharzii are thus discovered in the urine. The writer has been able once to demonstrate the presence of the eggs of the last-named parasite in the bloody urine of a missionary in Africa, where he had by long residence acquired the disease.

From the laboratory we are taught the well-known tests for albumin and sugar by which all sources of error may be eliminated in determining not only their presence but the quantitative analyses as well. The pathological conditions in which these substances are excreted are at times exceedingly grave, and it is of vital importance that their presence be discovered so that timely and judicious treatment may be instituted, or operation avoided which under such unfortunate conditions would be invariably fatal.[1]

In glycosuria the surgeon must know whether he is dealing with what Pavey designates as alimentary diabetes, in which the sugar eliminated by the urine is derived solely from the food as result of defective carbohydrate assimilation; or whether that almost hopeless condition of composite diabetes in which abnormal disintegration is taking place, is present.

No less important is the estimate of the amount of urea which is being eliminated in a given quantity of urine. Employing the simple apparatus of Doremus with the sodium hypobromite solution[2] within a few

[1] The following process is used at the Polyclinic laboratory in determining the presence of the tubercle bacillus in the urine and fæces: The sediment is thrown down in the centrifuge, the smear dried slowly over the Bunsen burner and stained with carbol-fuchsin, which is then warmed over the Bunsen burner for three or four minutes without being dried. Then it is washed with water and decolorized with five-per-cent. sulphuric acid, and again washed with water. After this ninety-five-per-cent. alcohol is added, which decolorizes the smegma bacillus, and again washed in water, counter-stained with methylene blue, and dried. With the one-twelfth oil immersion, the clusters of tubercle bacilli are readily seen.

[1] To determine the presence of albumin, the nitric acid and heat test is classical and reliable. The simplest quantitative analysis as recommended by Hare is to fill the tube for the centrifuge to the 10 c.c. mark with urine, to which is added 2½ c.c. of potassium ferrocyanide solution (one part to ten); 1½ c.c. of acetic acid is also added. After mixing the fluids well the centrifuge is rotated until the albumin is precipitated. Every $\frac{1}{10}$ c.c. mark on the tube represents one per cent. by bulk of albumin; that is, if the albumin extends up to the 3½ c.c. mark, the albumin amounts to thirty-five per cent.

Fehling's test in the demonstration of sugar and the quantitative analysis by means of yeast fermentation is another important laboratory process, without recourse to which the surgeon in a certain group of cases cannot satisfactorily work.

[2] Solution A—bromine and sodium bromite, each 125 gm.;

minutes' time, by the evolution of nitrogen gas in the presence of this, the amount of urea which is being carried off by the kidneys is readily demonstrable.

Non-parasitic chyluria (that form not due to the presence of filaria) is a rare affection, but it does exist, the fluid coagulating almost like jelly. In these conditions the microscope shows little that is pathological excepting some minute granules and oil droplets similar to those in milk (Osler).

The presence of blood in the urine, even in the most minute quantities, can in almost all cases be recognized by the microscope, and in those exceptional instances of hæmoglobinuria in which the corpuscles have disappeared, the blood crystals of Teischmann may be recognized by the addition of a drop of strong acetic acid to a few drops of urine placed upon a watch glass. For this condition of blood pigment in the urine in which the blood-cells are absent, Osler suggests the name methæmoglobinuria. He further states that when granular pigment or darkly pigmented urates or fragments of blood-discs do not point clearly to the presence of blood, the two absorption bands of oxyhæmoglobin, and more commonly the three absorption bands of methæmoglobin, of which the one in the red near G is characteristic, may be determined by the spectroscope. In general, however, the red and white blood corpuscles and filaments of clot are clearly recognizable with the one-sixth objective. Even without the microscope the presence of a very minute quantity of blood distributed through the urine can be recognized by Heller's test of adding a few cubic centimetres of urine to a drop or two of strong solution of caustic soda, and boiling the mixture. If blood is present, a bottle-green color is produced and the phosphates fall to the bottom of the test-tube in fine flakes, tinged brownish-red by the coloring matter of the blood (Hare).

When blood is found in the urine as a complication of papilloma of the bladder, particles of the broken-down tumor are very frequently found in the urine, and under the microscope the epithelial elements of this neoplasm are easily recognized and point clearly to the source of the hemorrhage. In hemorrhage from the kidney substance blood casts tell unmistakably of its source.

Chemistry demonstrates in the urine the presence of indican or indoxyl sulphate of potassium, a product resulting from the decomposition of albuminous products in the intestinal tract under the influence of bacteria. It is always suggestive of persistent constipation, is found in obstruction of the intestinal canal, carcinoma of the liver or stomach, in peritonitis, and is one of the symptoms of pernicious anæmia. Urine containing this substance if treated with two or three times its volume of hydrochloric acid turns a violet color.

A careful analysis of the various casts found in the urine under different conditions is of inestimable value. Blood casts indicating not only hemorrhage from the kidney, but acute inflammatory conditions, and casts composed of pus corpuscles and studded with micrococci suggesting pyelonephritis, are most valuable results in laboratory research. It also tells us of the existence of granular casts which indicate a chronic or subacute inflammatory process in the substance of the kidney, which is accentuated when fatty casts are found, and that hyaline casts have a grave significance, as they are most frequently associated with chronic interstitial nephritis, and that the waxy variety is very common in chronic suppurative processes, usually in the bones and joints.

To-day, one of the most attractive subjects of laboratory research is the blood, and although hæmatology is practically in its infancy, many valuable discoveries have already been made, and in the proper study of a patient a knowledge of the blood is as essential as that of the urine. It may throw no light upon many cases, but the reward will be tenfold in that particular instance in which the diagnosis is made definite and clear. It is necessary to know the normal blood thoroughly by constant practice in order to recognize the abnormal changes which may be present in a given case, and I can think of no more useful way of spending the time not taken up by practice than by going over these important features of laboratory technique.

A knowledge of hæmatology enables the surgeon to detect any form of anæmia and to determine whether it is a type of blood impoverishment which can be corrected, or whether it is of the graver or more pernicious forms which would either preclude an operation, or, if this were absolutely necessary, would enable him to announce to those entitled to information the gravity of the outlook. In ordinary practice it is not always essential to differentiate between a pernicious anæmia or a leukæmia, or whether this latter condition is present in the lymphatic or splenic-myelogenous form, for the reason that all of these graver varieties call a halt to operative measures when these can be avoided. But the anæmia which comes from malnutrition or malaria or chlorosis can be positively diagnosticated by a study of the blood.

The richness of the hæmoglobin may in a fair measure be determined by the comparative color test of the blood in proper solution, as observed through von Fleischl's hæmometer. When a low percentage of hæmoglobin is present, it is an indication to avoid any operative shock until the impoverished condition of the blood can be corrected by proper nourishment, by rest, or by medication, when this is positively indicated. This also suggests the aid of the microscope in a further investigation as to the condition of the corpuscular elements of the blood. It is advised by Mikulicz never to operate when the register of the hæmometer shows less than 35, and it would probably be safer to place the standard ten or fifteen points higher. Even in the simple forms of anæmia, the degenerative changes in the blood elements, especially in the red cells, are easily recognized, and are full of valuable suggestions.

When the red cells are near the normal count (about 6,000,000 to the cubic millimetre), they may still show certain characteristic deformities of individual cells (poikilocytosis) as well as variations in size, in the presence of microcytes and macrocytes which appear in the field, and which are not seen in the normal blood. If the red cells are paler in color than normal, if they undergo crenation or breaking at the edges, and do not form rouleaux, it is evident that anæmia is present.[1] The danger signals are still further in evidence when nucleated red cells (normoblasts) appear, and when there is added to these either the giant red cells (megaloblasts) or abnormally small microblasts the condition is still more serious, since these corpuscles never exist in the normal blood.[2]

Hæmatology further enables us to differentiate with reasonable precision between chlorosis and pernicious anæmia. In the former, though pale in color, the blood coagulates rapidly, while in the latter coagulation takes place slowly and the red corpuscles do not tend to the formation of rouleaux. The red cells in

water, 1,000 c.c. Solution B—sodium hydrate, 400 gm.; water, 1,000 c.c. Take of A and B each one part, water three parts. They are to be mixed only when needed for use. After the tube has been filled with the solution the pipette is filled with urine to the 1 c.c. and the point carefully introduced beyond the bend. The urine in the pipette is then expelled by compression of the bulb, care being taken not to force any air into the tube.

[1] The average red corpuscle (normal) is 7 μ in diameter.

[2] A normoblast is a nucleated red cell not over 10 μ in diameter, with a nucleus not more than one-half the diameter of the same.

chlorosis (which are small and paler than normal and are frequently deformed) vary from 4,000,000 to 2,000,000, rarely falling as low as 1,000,000, while in pernicious anæmia, in which the average diameter of the red cells is increased, the count rarely rises above 1,000,000, and often below this. Cabot gives 1,000,000 as the average number per cubic millimetre. The white cells are also diminished, varying from 4,200 to as low as 500 with lymphocytosis as a prominent feature. Megaloblasts are found in both conditions, but while plentiful in pernicious anæmia are rarely noticed in the milder disease chlorosis. The more megaloblasts in pernicious anæmia, the more hopeless the case.

The surgeon would be extremely unfortunate to fail in the recognition of these often obscure lesions, and, if possible, to correct them before subjecting his patient to the severe ordeal of an operation. In the early recognition of septic processes—chiefly pyogenic—surgery can no longer disregard the value of the blood count, especially the estimation of the leucocytes.

The relative number of leucocytes in a given quantity of blood, or their proportion to the red corpuscles, can be readily determined by the use of the Thoma-Zeiss apparatus, which, as is well known, consists of two pipettes, one for the red and one for the white, with a well-outlined and peculiarly constructed slide or counting apparatus, and employed with the ordinary one-sixth laboratory objective. The differentiation by the use of the Daland hæmatocrit is not considered sufficiently exact to be satisfactory in the hands of the majority of hæmatologists. It is essential in making these differentiations to bear in mind the normal conditions that at the sea level the average number of red cells per cubic millimetre is 5,000,000 in men, and 4,500,000 in women, and 6,000,000 in the young and more vigorous adults, while the white cells average about 7,500 per cubic millimetre for each sex.

Certain conditions not considered normal influence the number of leucocytes, since in the later months of pregnancy they are moderately increased, and after parturition and during the early weeks of lactation a leucocytosis may be present without pathological significance. After hemorrhage the leucocyte count is increased, and in diphtheria, erysipelas, trichiniasis, all extensive forms of endometritis, and all acute pyogenic processes, leucocytosis exists except in those cases in which the vitality of the individual has been overwhelmed by the severity of the septic process, in which condition the leucocytes no longer respond to the demand for the protection of the tissues, and are not present in the superficial blood in even normal proportions. It is probable that the application of this knowledge is more profitable at present in a study of the various lesions of the abdominal and thoracic organs. We know that in a certain proportion of cases of infection temperature does not always indicate the increasing gravity of the lesion, while the degree of sepsis can be in great measure determined by the leucocyte count. In impaction of fæces, extrauterine pregnancy, floating kidney, gall-stone colic, renal colic, ovarian neuralgia, intussusception, volvulus, internal hernia, twisted pedicle, etc., there is no leucocytosis unless the condition be complicated with an acute septic process. In abscess of the liver the leucocyte count ranges from 12,000 to 48,000, while there is a well-marked increase in all the septic pyogenic processes of the lungs and the pleura.

In osteomyelitis the leucocyte count ranges as a rule from 15,000 to 25,000, and at times higher. Since in the early stages of this disease it is at times difficult by subjective symptoms to differentiate between rheumatism or gout, the leucocyte count is invaluable in demonstrating at once the pyogenic process.

In that very rare disease, trichiniasis, the leucocytes register sometimes as high as 30,000, but the special feature is the presence of a large number of eosinophile cells, sometimes as high as fifty per cent., and in rare cases sixty-seven per cent. of the total number of leucocytes being this form of corpuscle. A very considerable number of cases have been reported within the last year in which the diagnosis had been determined by the presence of eosinophiles.

Not only can the presence of the plasmodium malariæ be recognized in the red blood cells, but hæmatology is already able to distinguish the different varieties of the malarial parasite. It has been shown that the tertian organism takes forty-eight hours to develop and undergo sporulation; the quartan seventy-two, while the æstivo-autumnal passes through irregular phases, varying from forty-eight hours to several days.

We are enabled to demonstrate also the presence of the spirochæte of relapsing fever discovered by Obermeier in 1873. Although the corkscrew or spiral threads are rarely seen unless the blood is examined in the height of the fever paroxysm, diplococcus-shaped bodies believed to be the spores of this organism are found in the periods of remission.

The time allotted has permitted hardly more than a suggestion of the methods of laboratory research, applicable in the daily routine of surgical practice. To me the moral of the lesson is that the science and art of surgery are inseparable.

THE PROGRESS AND TENDENCY OF HYGIENE AND SANITARY SCIENCE IN THE NINETEENTH CENTURY.[1]

By GEORGE M. KOBER, M.D.,
WASHINGTON, D. C.,
PROFESSOR OF HYGIENE, GEORGETOWN UNIVERSITY.

Hygiene is a department of medicine whose object is the preservation and promotion of health, and deals, therefore, with all the factors likely to influence our physical welfare. It is not an independent science, but rather the application of the teachings of physiology, chemistry, physics, meteorology, pathology, sociology, epidemiology, and bacteriology to the maintenance of the health and life of individuals and communities. The subject is very properly divided into personal and public hygiene. In the former the doctrines are applied to individuals, in the latter to communities and States.

This branch of medicine has received such an impetus within the last few decades that many persons regard it of modern origin; such, however, is not the case, for on turning to early history we almost invariably find that the health of the population has been made a subject of legislation. Hygiene was practised by the Egyptians, the old Indians and Hebrews, and a study of the habits of the primitive peoples shows that a desire to prevent disease is innate to all men.

The Greeks and Romans paid special attention to the physical culture of their youth; they also paid much attention to the water-supply, and Athens was provided with sewers at an early period of her history.

The teachings of Hippocrates, 400 B.C., doubtless bore many fruits, and whether it is true or not, as stated by Galen, that he ordered, during a pestilence at Athens, aromatic fumigation and large fires in the streets, we have at least his writings on air, water, soil, habitations, and occupations, and his views of local and seasonal influences on sporadic and epidemic diseases. In Homer's "Odyssey" reference is made to Ulysses purifying his house with burning sulphur,

[1] Oration on state medicine before the fifty-second annual meeting of the American Medical Association, at St. Paul, Minn., June 4–7, 1901.

and Aristotle, in his "Politica," shows his sanitary acumen when he says: "The greatest influence upon health is exerted by those things which we most freely and frequently require for our existence, and this is especially true of water and air."

The Romans, amidst their military operations, found time to construct the "cloaca maxima" about 2,400 years ago, which not only served for the removal of refuse, but also helped to drain many of the marshes, and constitutes the principal sewer of modern Rome. Aqueducts were made to cover miles upon miles of the surrounding plains, and their splendid ruins, many of which have been restored and are now used for their original purpose, attest the munificence and abundance with which the first of sanitary requisites was supplied to the Eternal City. It is stated that between 400 B.C. and 180 A.D. about eight hundred public baths were established, among them the "Thermæ Caracallæ," which alone would accommodate three thousand bathers at one time.

During the reign of the Cæsars attempts were made to drain the Pontine Marshes; sanitary officials and physicians to the poor were appointed and homes for poor girls and orphans were established. In the mean time the true spirit of Christianity asserted itself, and we read of the establishment of hospitals as early as the fourth century; these were speedily followed by infant and orphan asylums and homes for the poor and incurable. During the Middle Ages sanitation received a decided check; ignorant and brutal prejudices appear to have been the ruling spirits, and for many reasons it was the most insanitary era in history.

Pests and Insanitary Conditions of the Middle Ages.—About this time most of the towns in Europe were built in a compact form, surrounded with walls; the streets were narrow and often winding for defensive purposes, shutting out light and air from the houses. The accumulation of filth was simply frightful. Stables and houses were close neighbors, human filth was thrown on the streets or manure heap. The dead were buried within the churchyards. Sewers and aqueducts having been permitted to fall into disuse, the inhabitants were compelled to resort to wells with polluted subsoil water. All the conditions were favorable for the spread of infectious diseases, and in the fourteenth century alone the Oriental or bubonic plague, according to Hecker, carried off one-quarter of the population of Europe, or over twenty-five million victims.

Although this disease had been described as early as the third century B.C., a lamentable state of ignorance is shown, when we remember that the majority of people regarded the plague as the dispensation of God's providence, an evidence of divine wrath, which they hoped to allay by all sorts of self-inflicted punishments, and the passion plays of Oberammergau and elsewhere originated about this time. Others accused the Jews of being the cause, and hundreds were burned at the stake until Pope Urban IV. placed them under his special protection. The Faculty of Paris attribute the epidemic to the conjunction of planets on a certain day in 1345, and the Faculty of Leipzig, with equal gravity, asserted that it was connected with earthquakes, unseen waves of air, inundations, etc. Venice, alone of all Europe, took a sensible view of the matter, and for the first time in history, in 1348, appointed three guardians of public health, and the rules adopted later to isolate infected houses and districts for forty days has given rise to the term quarantine from *quaranta giorni*.

The repeated invasion of the Oriental pest appears to have everywhere compelled some sanitary efforts, and an imperial decree in 1426 required the appointment of city physicians throughout Germany, whose duty it was to adopt preventive measures. A city ordinance of Nürnberg in 1562 gives detailed directions as to the quality of bread, beer, and wine offered for sale, the cleaning of streets and houses, the disposition of infected clothing and bedding, the fumigation with sulphur and straw of pest-houses, etc.

In 1685 Prussia established a central medical bureau, and appointments of health officers and privy medical counsellors were made, whose duties consisted in advising the men entrusted with the care of the government on matters relating to public health, and some of these titles are still in vogue in Europe. At the beginning of the eighteenth century, Prussia, upon being threatened with an invasion of the bubonic plague from Austria, created the "Collegium Sanitatis," popularly called the "Pest College," which was really the beginning of the present State board of health. In 1762 a sanitary council was established in every Prussian province, for the prevention of disease among man and animals. About the same time sanitary improvements in the way of widening streets for the purpose of supplying more air and light to the habitations, and better methods for the collection and removal of the wastes of human life was introduced, but, broadly speaking, at the close of the seventeenth century the habits of the people in Europe were generally filthy and in striking contrast to those observed among the most untutored savages of the present day.

In Madrid, we are told by Barcome, in his history of epidemics, "that not even a privy existed in 1760. It was customary to throw the ordure out of the windows at night, and it was removed by scavengers the next day. An ordinance having been issued by the king that every householder should build a privy, the people violently opposed it as an arbitrary proceeding, and the physicians remonstrated against it, alleging that the filth absorbed the unwholesome particles of the air which otherwise would be taken into the human body. His majesty, however, with commendable zeal, persisted, but many of his citizens, in order to keep their food wholesome, erected privies close to their kitchen fireplaces."

With such unsanitary conditions we need scarcely be surprised that the mortality in towns was greater than their birth-rate, and that the city population had to be recruited continually from the country. Toward the close of the eighteenth century many sanitary reforms were effected, however, especially in connection with infant and orphan asylums, and the management of schools and prisons. Of special importance is the brilliant discovery, or re-discovery, of vaccination by Jenner in 1796.

Progress of Sanitation in the Nineteenth Century.—The nineteenth century can boast of many advances in hygiene, particularly since the European invasion of cholera in 1830. The English towns which had been visited by this disease and those fearing similar scourges were willing to profit by their sad experience, and freely instituted sanitary reforms in the establishment of sewers, public water supplies, sanitary homes, etc.

The example of England was followed by all civilized nations, with similar results. The effects of sanitation, as taught by Dr. Parkes, were demonstrated during the Crimean War, and, as beautifully expressed by Virchow, during our Civil War reached "the highest point in human efforts ever attained in a great war," and we may proudly add have even been excelled during our late Spanish-American War.

Progress of Sanitation in the United States.—While the people of the United States were not slow in adopting and originating sanitary measures of great value, our ideas of personal liberty, guaranteed to us by the Constitution, evidently prevented early legislation in matters of public health, for fear that such legislation might affect the personal habits of the citizen

and lessen his freedom of action. Dr. Samuel W. Abbott, in his masterly exposition of "The Past and Present Condition of Public Hygiene and State Medicine in the United States," records, however, the gratifying fact that the early colonists recognized the need of preserving their records, which constitute the foundation stone of public hygiene, by enacting a law in 1639 "that there be records kept of the days of every marriage, birth and death of every person in this jurisdiction."

The importance of vital statistics is not fully appreciated at the present day, and yet, as remarked by Dr. Billings, "when we wish to study the healthfulness of a city, whether it is getting better or worse, or judge correctly the effect of certain sanitary laws, we should not only know the number of deaths, but also the amount and character of the prevalent disease, together with accurate information as to the number of population at different ages." It is a matter for regret, therefore, that even now only ten States—Connecticut, Delaware, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Rhode Island, and Vermont—have anything like a satisfactory system of vital statistics.

According to Abbott: "Up to the close of the eighteenth century and for several decades of the nineteenth, almost the only health legislation which was enacted in the different States in the Union consisted in a few laws relating to smallpox, since this pestilence was scarcely ever absent for many years at a time from any city or village, till after the general introduction of vaccination."

Dr. Waterhouse, of Cambridge, having secured a supply of vaccine lymph from Dr. Jenner, introduced vaccination in Boston in 1800, and Dr. Seaman in New York in 1801. In the same year President Jefferson received some virus from Dr. Waterhouse and was vaccinated by Dr. Grant, of Georgetown.

The invasion of cholera from Canada in 1832 and the epidemic of 1848–49 here, as in Europe, aroused public interest in sanitary reforms, and the legislature of Massachusetts in 1849 appointed a commission to make a sanitary survey of the State, and we are told by Dr. Abbott "that this was done none too soon, for in that year the general sanitary condition of the State, as shown by the report of the commission, was deplorable and the death rate unusually high. Only a few towns had then introduced public water supplies. Cholera was beginning to appear again, and dysentery and other infectious diseases were more destructive than they had been for many years."

Health Boards.—New Orleans having lost eight thousand victims by cholera in 1832, out of a population of about fifty-five thousand, and anxious to maintain a quarantine, secured the enactment of a law in 1855 for the establishment of a State board of health; in 1869 a more comprehensive board was established in Massachusetts, followed in 1870 by California, since which time nearly all of the States and Territories—forty-two in number—have followed the example. *Pari passu* and in many instances preceding the establishment of State boards of health, sprung into existence our local boards of health, who adopted measures for the control and restriction of infectious diseases, for the abatement of local nuisances, for the sanitary inspection of the food supply, schools, public buildings and institutions, and tenements; street cleaning and removal of refuse, registration of vital statistics, supervision of burials and of municipal water supply, sewerage and sewage disposal, care of bathing establishments, regulation of offensive trades, etc.

Effects of Voluntary Organization upon Sanitation.—In September, 1872, the American Public Health Association was organized; in 1873, the Section on State Medicine of the American Medical Association was created; since then the American Climatological Association, the Sanitary Council of the Mississippi Valley, the American Sanitary Association, and the American Health Resort Association have been organized, and numbering, as they do, among their members some of the best minds in the profession, much good has been accomplished by these bodies, and the so-called "sanitary conventions" in moulding public opinion and in framing and recommending health laws. There is no doubt, however, that all these organizations were stimulated into existence by the lofty tenets of our code of ethics,[1] in which the duties of the profession to the public were prescribed as early as 1847.

Indeed, the American Medical Association, according to Dr. N. S. Davis, Sr., gave prominent attention to State medicine and sanitation from its first meetings. At the second annual meeting, in 1849, standing committees were appointed on forensic medicine and on hygiene, and reported annually on these topics and on meteorology, medical topography, and epidemic diseases until 1860, when work in sections was commenced. Dr. A. N. Bell, of New York, delivered the first address on State medicine in general session of the association in 1874, followed in 1875 by Dr. N. I. Bowditch, of Boston.[2] In this connection, I may say that there is need of reliable information on the geographical distribution of diseases like goitre, cretinism, etc., and county medical societies would contribute much to the common fund of knowledge by placing on record information of this character.

National Board of Health.—The cholera epidemic of 1872 and 1873 resulted in the appointment of a commission by Congress. This, together with the yellow-fever epidemic of 1878 in the Southern States, affecting, according to Sternberg, over seventy-four thousand persons, with sixteen thousand deaths, called attention to the necessity of some central sanitary organization. In March, 1878, Congress created a national board of health, whose duty it was to make investigations into the causes and means of prevention of contagious and infectious diseases, to indicate measures of national importance, and to be a centre of information for all matters relating to public health. For want of appropriation this important body has ceased to exist, and since 1883 the duties relating to international and interstate quarantine have been discharged by the surgeon-general of the United States Marine-Hospital service; this bureau, apart from the management of hospitals and stations for the care of sick and disabled seamen of the merchant marine, has also undertaken the collection and dissemination of mortality statistics and sanitary information, scientific investigation into the causes of disease, the physical examination of immigrants under the law, excluding those affected with contagious disease; service in the office of consuls at foreign ports to assure the accuracy of bills of health—and other miscellaneous duties. Since Congress has failed to act upon the President's repeated recommendation and the petition of numerous medical societies for the creation of a national health

[1] Article 1, paragraph 1, reads: "As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession as on subjects of medical police, public hygiene, and legal medicine. It is their province to enlighten the public in regard to quarantine regulations, the location, arrangement, and dietaries of hospitals, asylums, schools, prisons, and similar institutions; in relation to the medical police of towns, as drainage, ventilation, etc., and in regard to measures for the prevention of epidemic and contagious diseases, and when pestilence prevails it is their duty to face the danger and to continue their labors for the alleviation of the suffering, even at the jeopardy of their own lives."

[2] Information kindly furnished by Drs N. S. Davis, Sr., and George H. Simmons, letter of April 18, 1901.

establishment, there is no good reason why the scope of duties and powers exercised by the Marine-Hospital service should not be enlarged. Indeed, the last Congress appropriated sufficient money for the erection of a laboratory "for the investigation of infectious and contagious diseases and matters pertaining to the public health," which marks the beginning of a new era in national sanitary legislation.

National and International Quarantine.—The question of an efficient system of national and international quarantine against Asiatic cholera, yellow fever, smallpox, typhoid fever, bubonic plague, and leprosy has engaged the attention of sanitarians for years, especially since it become known that these diseases, particularly cholera, are generally carried along the highways of travel and commerce. Special efforts were made after the completion of the Suez canal and other rapid-transit facilities, to guard Europe from the invasion of cholera from India, and since 1892 these efforts have been quite fruitful. At all events, with efficient quarantine regulations involving inspection of vessels, passengers, and crew, the detention of the sick and disinfection of all others, including personal effects, cargo, and vessels, and proper notification, we have been enabled to keep these diseases from our shores, and if other nations do the same, they should be restricted to their original home. General Wyman's plan, as outlined in his address before the Pan-American Medical Congress, contemplates an international system of sanitation; while his proposition refers especially to yellow fever in the western hemisphere, it is equally applicable to the home of cholera and the Oriental plague.

In the light of the recent researches by Reed and Carroll as to the transmission of yellow fever by means of mosquitos, our views concerning quarantine and disinfection in this disease may have to be modified, but in the mean time the fight against the mosquitos will go on; whether this will be effectually accomplished by insecticides and screens, or the more rational method of drainage of the soil, remains to be seen; in either event malarial countries will likewise be benefited.

Has Human Suffering been Mitigated and Human Life Greatly Prolonged by Efforts in Sanitation?—Our answer is an emphatic "Yes." Professor Finkelnburg, of Bonn, estimates that the average length of human life in the sixteenth century was only between eighteen and twenty years; at the close of the eighteenth it was a little over thirty years, while today it is over forty years; indeed, the span of life since 1880 has been lengthened about six years, as shown by statistics in Mulhall's "Dictionary of Statistics" (fourth edition, London, 1899).

The mortality of London between 1660 and 1678 was 80 per 1,000 of inhabitants; from 1728 to 1780, 51 per 1,000; from 1801 to 1835 it was still 29, while at the present time it averages between 17 and 19 per 1,000.

Influence of Sewers and Public Water Supplies.—Without underestimating the brilliant achievements of Jenner's discovery of vaccination in 1796, which as a preventive measure has saved millions of lives, no two factors have contributed so much to the general result as the improvement of the air we breathe and the water we drink. Indeed, we have ample evidence that, with the introduction of sewers and public water supplies, the general mortality in numerous cities, during the past forty years, has been reduced fully one-half, the good effects being especially shown by a marked decrease in the number of cases of typhoid fever, diarrhœal diseases, and consumption. The vital statistics of Great Britain furnish the proof. The mortality of Salisbury within the last thirty years has been reduced from 40 to 16 per 1,000; at Dover, from 28 to 14 per 1,000; at Rugby, from 24 to 10 per 1,000; at Croydon, from 28 to 15 per 1,000, and at Matlock, from 18 to 9 per 1,000.

The history of every sewered city shows a lessening of the typhoid death rate subsequent to the construction of the sewers, and that the typhoid rate is always higher in sections supplied with privy pits and box privies, than in the houses connected with sewers. In 1895 the speaker pointed out that typhoid prevailed in the city of Washington and suburbs in 1 of 81 houses with privies, and in only 1 in 149 of those connected with sewers, and the health officer of Nottingham has since then presented similar evidence. The only reasonable explanation for this is that sewers carry away the filth that otherwise would contaminate the soil and ground water, but even if there were no wells, these makeshifts are still a source of danger in so far as they favor the transmission of the infection by means of flies, nor can the possibility be ignored that the germs in leaky or overflowing boxes may reach the upper layer of the soil, and, with pulverized dust, gain access to the system. This conclusion, and the agency of flies in carrying the germs from box privies and other receptacles from typhoid stools to the food supply, was enunciated in my report in 1895 and appears to have found ample support in the experience of the late Spanish-American war.

Influence of Improved Water Supplies.—According to Dr. Abbott, the number of towns in the United States before 1800 having a public water supply was only 16, supplying about 2.8 per cent. of the existing population; in 1850 there were only 83 public water works, supplying about 10.6 per cent. of the census population; in 1897 the total number was 3,196, supplying about 41.6 per cent. of the population.

A summary of the evidence on this subject reveals the significant fact that cities, both at home and abroad, in which there has been the most marked decrease in typhoid-fever death rate, are those in which a pure supply has been substituted for a pre-existing contaminated one. Thus, for example, the typhoid-fever death rate in Boston in 1846–49 was still 17.4 per 10,000; in 1890–92 it had fallen to 3.2 per 10,000, the city having in the mean time expended $25,000,000 on its water supply. The typhoid-fever death rate in Chicago from 1890 to 1892 averaged 12.5 per 10,000. After improving the water supply it fell with every step in improvement until last year it was only 1.9 per 10,000, a total reduction of 84.8 during the decade. The rate from this disease in Lawrence, Mass., for five years prior to 1893, was 12.7 per 10,000. After the establishment of sand filters, in September, 1893, the rate fell during the first twelve months to 5.2 per 10,000.

Munich was notorious for its excessive typhoid-fever death rate, it being 29 per 10,000 in 1856. With the introduction of a pure water supply and improved sewer system it has fallen to less than 2 per 10,000.

The experience of London, Berlin, Vienna, Albany, and a host of other cities has been precisely the same.[1]

Sewage Disposal and River Pollution.—When we remember that in 1896, 41 per cent. of our population lived in towns having public water supplies, and only 28.7 per cent. in sewered towns, we fear that the municipal authorities have failed to recognize the necessity that a system of public sewerage must go hand-in-hand with the public water supply, the neglect of which simply compels recourse to the various makeshifts for the

[1] In 25 cities using unfiltered water the average typhoid death rate is still 7.7 per 10,000; in 5 American cities supplied with water filtered by the American process, the rate is 5.5, against a rate of 1.1 per 10,000 in cities supplied with water filtered by the natural or English method. The average rate of 5 cities in Europe supplied with mountain springs or deep wells from unpolluted sources is only 0.7 per 10,000.

collection and removal of excreta, and leads to soil pollution and all the other evils already referred to.

In view of the fact that self-purification of rivers is a slow and uncertain process, and that streams once polluted with excrementitious matter cannot be considered a safe water supply, it is high time for civilized communities to take steps toward removing the danger to be found in rivers, which are the sewers and at the same time the sources of public water supplies.

We know, from statistics collected by the Marine-Hospital service, that the towns and cities located on the banks of the Ohio, Potomac, Mississippi, Merrimac, Connecticut, Missouri, the Red, the Columbia, and Wabash rivers show a marked prevalence of typhoid fever, confirming what has elsewhere been proved, that this disease, as also cholera, dysentery, and diarrhœal diseases, can be carried from one town or city to another by means of water courses. There were probably no fewer than thirty-five thousand deaths caused by typhoid fever alone throughout the United States last year, and, based upon an estimated mortality of ten per cent., it is within reason to assume a yearly prevalence of three hundred and fifty thousand cases of this disease. The average duration of a case of typhoid fever is not less than thirty days. If we calculate that an average of $1 a day is expended for care, treatment, and loss of work, and that the value of a human life is $5,000, we have a total loss in the United States of $185,500,000 per annum, from one of the so-called preventable diseases. Reduce the prevalence of this single disease one-half, which has been accomplished in England, and the oft-recurring question, "How is it our fathers got along without these so-called modern improvements?" will be satisfactorily answered from an economic point of view.

One of the most pressing needs is an investigation into the pollution of water supplies when such pollution affects or threatens to affect the sanitary condition of the people of more than one State, because the individual States are powerless to protect themselves against the misdeeds of their neighbors. Mr. Barthold's bill for the appointment of a river-pollution commission was defeated; yet that same Congress appropriated $40,000 for the extermination of the gypsy moth. England enjoyed the benefit of such a commission as early as 1855, and, in order to prevent, remedy, and remove the danger of polluted water supplies, adopted a comprehensive system for the disposal of sewage and water filtration, the fruits of which have already been referred to.

No community or individual has a right to pollute streams used for public water supplies any more than a man has to contaminate his neighbor's well. This principle is very well appreciated by some of the nations in Europe. Thus the inhabitants of a town in Belgium suffered from the effects of a river polluted by the French, and the French government not only compelled the offending town to dispose of its sewage by irrigation, but also granted a subsidy for this purpose.

In the interest of public health it is to be hoped that every State in the Union will take steps toward the prevention of river pollution, except when towns are located close to the sea, and no lower towns are obliged to use the water for drinking-purposes.

In 1878 the British government appointed a committee to inquire into the several methods of sewage disposal, and concluded that it can be best and most cheaply disposed of by the process of land irrigation for agricultural purposes; but as this is not always practicable other modes of dealing with sewage have been proposed.

It is a gratifying fact that within the past ten or twelve years over one hundred communities in the United States have established plants for the disposal of sewage. The first attempt was made in 1872 at the State insane asylum, Augusta, Me., since which time seventy-eight plants for the disposal by irrigation, and fifteen by chemical treatment, have been established and over forty more projected.

Pure Food and Drug Legislation.—The first movement toward securing comprehensive legislation against the adulteration of foods and drugs in this country was made in 1879. This is all the more surprising because Dr. Mann, in his "Medical Sketches of 1812," remarks that "the bread on the Niagara was made of damaged flour, such as was either not nutritious or absolutely deleterious." It was believed also that the flour contained in some instances an earthy substance, and that its adulterating substance was plaster of Paris. Again, during the Civil War, as early as the winter of 1861–62, an extract of coffee furnished the troops in the vicinity of Alexandria produced nausea and vomiting, and subsequently a government contractor, for having practised food adulteration, was sentenced to a protracted imprisonment.

Instances, therefore, were not wanting pointing to the necessity of such laws; nevertheless, it was not until 1881 that three States, New Jersey, New York, and Michigan, passed laws to prevent the adulteration of food and drugs. The law in New York commenced in the summer of 1882. At the close of the year 286 samples of food and drugs had been submitted to the public analyst for examination, of which 194 had been reported on. Of 119 samples of food, 50 were found adulterated; while of 75 samples of drugs, 32 were adulterated.

Since 1883 quite a number of States have enacted similar laws, but I regret to say that in spite of the absolute necessity for national legislation, which has been agitated ever since 1892, so far every bill presented to Congress has failed to become a law, and food adulterated in one State can be taken to another and sold. It would lead me entirely too far even to touch upon all the frauds which are daily perpetrated. Some adulterations are harmful, others are not. I will simply refer to a very universal article of food, viz., milk. New York City obtains its milk supply from five States, and it amounted in 1896 to nearly seven hundred and twenty-nine thousand quarts a day. Analysis of the milk sold some years ago showed an average dilution with thirty-three per cent. of water. The State inspector found twelve per cent. water added and twenty per cent. of cream removed, the fraud amounting to over $10,000 a day. The results in St. Louis, Chicago, and elsewhere were similar, and indicated the desirability of stringent laws to protect the pocket of the consumer, but when we remember the frightful infantile mortality, and the fact that the speaker has recently presented his conclusions, based upon one hundred and ninety-five epidemics of typhoid fever, ninety-nine of scarlet fever, and thirty-six of diphtheria, and that fifty-two of these outbreaks occurred in this country since 1882, we see at once that the milk traffic should be under strict sanitary control.[1]

Laws Regulating the Sale of Drugs and Poisons.—Forty-two States and Territories have enacted laws to regulate the sale of poisons, but a careful study shows that they should be amended, and greater restriction placed on the sale of poisons generally. A recent investigation by a committee of the Medical and Surgical Society into the extent of the opium and drug habit in the District of Columbia developed some interesting facts, and led to the conclusion that one class of subjects have developed the opium habit by

[1] The results achieved by the health officers of every large city, notably by Reynolds, of Chicago, Wende, of Buffalo, and Woodward, of Washington, in the reduction of infantile mortality, amounting in some instances to over fifty per cent., show the advantage of pure-food legislation.

the use of the milder preparations of opium and some of the various proprietary or secret remedies commonly employed as domestic remedies, such as paregoric, McMunn's elixir, chlorodyne, black drop, soothing syrup, diarrhœa mixtures, pain-killers, etc. Those of another class have evidently acquired the habit by the constant use of prescriptions containing opium, or its preparations, for the relief of pain, the individuals being at first quite unconscious of the enslaving nature of the drug. Still another class of persons belong to the moral degenerates of fast men and women who have acquired the habit by contact with opium habitués, including opium smokers, and through solicitation, invitation, and persuasion have fallen victims to the vice. Since the opium habit is often established by the unauthorized and indiscriminate renewal of prescriptions containing opiates, the New York legislature very wisely enacted, in 1886, a law that no pharmacist shall refill more than once prescriptions containing opium or morphine, or preparations of either, in which the dose of opium shall exceed gr. ¼, or morphine gr. $\frac{1}{20}$, except with the verbal or written order of a physician.

It is clearly the duty of the State to close opium dens and restrict the sale of poisons, and in regard to the sale of patent and proprietary medicines containing poisonous drugs, the contents should be expressed on the label and the word poison added.

Patent and Proprietary Medicines.—By the term patent medicine, as properly employed in this country, England, and Europe generally, it must be understood that the composition is known and can be seen at the patent office. The proprietary medicine is a secret preparation protected by a trade-mark in this country, and hence preferred by the owner, but both are vaguely termed by the public patent medicines. Up to December 10, 1900, the United States Patent Office had issued patents on the following:[1] disinfectants, 321; extracts, 250; hair dyes and tonics, 48; insecticides, 180; internal remedies, 376; plasters, 56; topical remedies, 371; veterinary, 78. Trade marks:[2] drugs and chemicals, 319; medical compounds, 5,974, and increasing at the rate of about two hundred and fifty a year.

The proprietary medicines are subject to the control of the State authorities, and if containing alcohol in sufficient quantity to be intoxicants are subject to internal revenue laws; but so far as my knowledge extends, little or nothing has been done in this country and in England to control the sale of secret remedies. Dr. G. Danford Thomas, coroner of London and Middlesex, before the International Congress of Hygiene, in 1891, very justly urged that all proprietary medicines should be under the patent laws, because the composition is at least disclosed; he would abolish licenses to sell them and confine the sale to chemists and druggists only. In these matters we could certainly profit by the example of the Japanese, Italian, French, and German laws. In the interest of public health the profession should demand adequate legislation; as it is now, hundreds of these proprietary preparations, the composition of which need not even be disclosed to the Patent Office, are advertised in medical journals.

Industrial Hygiene.—The relations of occupation to health and life were studied as early as 1700 by Ramazzini, an Italian physician, and since then numerous monographs have appeared. We know today that persons habitually engaged in hard work, especially in factories and indoors, present a higher mortality than persons more favorably situated, and that the character of occupations influences, to a great extent, not only the average expectation of life, but also the prevalence of certain diseases. We know, for example, that tuberculosis is much more frequent among persons engaged in dust-inhaling occupations, and that the sharp, angular particles of iron and stone dust are more liable to produce lesions of the respiratory mucosa than coal, flour, grain, and tobacco dust. We know, too, that certain establishments, like slaughter houses, glue, soap, and candle factories, chemical factories, etc., are more or less productive of noxious and offensive gases, and that workers in lead, mercury, arsenic, phosphorus, poisonous dyes, etc., suffer especially from the injurious effects, and that other occupations, such as mining, railroading, and contact with moving machinery, involve special danger to life and limb.

For all these reasons the laboring classes need special protection, and in order to render this efficient it must be provided for by the enactment and enforcement of suitable laws. In 1864, 1867, and 1870 England enacted the so-called factory laws. According to Miss S. S. Whittlesey's "Essay on Massachusetts Labor Legislation," child labor, here as in England, was the first aspect to receive attention in legislation as early as 1836. The first law as regards safety and sanitation was enacted in that State in 1877, since which time, from information kindly furnished by the Hon. Carroll D. Wright, of the United States Department of Labor, thirty-two States have enacted similar laws, including legislation requiring seats to be furnished saleswomen in stores and shops. Indeed, in some of the States the latter requirement is the only sanitary regulation. As a result of these laws, the majority of which were enacted during the last decade, commendable progress has been made in the way of ventilation, heating, lighting, removal of dust and injurious gases, means of escape in case of fire, and prevention of injuries by moving machinery.

It is quite true there are other factors which affect the health and longevity of wage earners adversely. So, for instance, unsanitary dwellings, faulty nutrition —the results of badly prepared food and cold lunches —cannot fail to lower the power of resistance to disease, especially when the individual, in consequence of these very causes, has also become a victim of the alcohol habit.

Sanitary Dwellings for Wage Earners.—No field affords better opportunity for philanthropic work than the erection of sanitary homes for wage earners at reasonable rentals, the encouragement of cookery schools, the establishment of sanitary lodgings, model eating-houses, and other betterments of industrial conditions.

The vital statistics of London show that the mortality in the improved dwellings for wage earners is far below the general mortality of the city, the difference being specially marked in the infantile mortality; the general average during the five years ending December, 1890, was 153 per 1,000, while in the "George Peabody" and the "Metropolitan dwellings" it was only 136 and 121 respectively.[1]

[1] Information kindly furnished by Dr. J. B. Littlewood, of the Patent Office.

[2] Information collected from files of the United States Patent Office, by the author.

[1] At a recent meeting of the American Social Science Association, held in Washington, April 18, 1901, Mr. J. H. Patterson, Dayton, Ohio, read a paper on factory sanitation and described a large manufacturing plant of which he is the head, and their close adherence to the principles of hygiene and the uplifting of mankind. The interior of the factory is painted in cheerful colors, extra windows were made to give light, forced ventilation to afford plenty of fresh air, and all dust and acid fumes are carried away by exhaust fans. Bathrooms and well-furnished toilet-rooms are on all the floors. All seats have backs. Clean aprons are furnished by the company, and a dining-room where hot meals are served and a course in domestic economy is conducted. The grounds around the factory, and the houses of the employees, are healthful and attractive. "We have demonstrated," said Mr. Patterson, "that this system pays the employee, the manufacturer, and the buyer: in the health of one, profit of the second, and the improved quality of the product purchased by the third." Bulletin No. 31, Department of Labor, November, 1900, contains an

Rural Hygiene.—When we consider the fact that over seventy per cent. of our population reside in rural districts, that the "bone and sinew" of these are engaged in agricultural pursuits, and that they do not enjoy the benefits of enforced sanitation by local health boards, we see at once the desirability of the family physician extending useful suggestions on healthful building-sites and homes, disposal of house wastes, the importance of a pure water supply, wholesome and properly cooked food, etc. As it is now, the diet is faulty, especially the hot biscuits, greasy fried dishes, while wells and privies are often dangerous neighbors. The undue prevalence of typhoid fever in rural districts could be materially checked by disinfecting the stools with three times the volume of boiling water and the adoption of the earth-closet system. This is all the more important since infection is often spread through the milk supply, and many of our urban population contract disease in the country during the summer months. While prompt disinfection of the excreta is the only rational method, we should also make an effort to get rid of the flies by prompt disposal of the horse manure in which they breed, the abandonment of open privies and surface pollution, removal of garbage and other fly-breeding matter.

Sanitation of Prisons.—Most commendable progress has been made in the construction and management of modern prisons. The mortality at the close of the last century, among prisoners in some of the French prisons, was 250 per 1,000; between 1840 and 1849 it was still 80.2 per 1,000 at St. Gallen, while to-day it is less than 30 per 1,000. Tuberculosis, typhoid fever, diarrhœa, croupous pneumonia, and mental disorders are the most prevalent diseases, but much will be done in future to reduce the excessive mortality by improved lighting, heating, ventilation, good food, bathing facilities, etc.

In some of the damp, dark, and gloomy prisons of Germany over fifty per cent. of all the deaths are from consumption. In the Millbank prison of London, from 1825 to 1842, there were 175 deaths, of which no less than 75 were due to tuberculosis. Besides, 90 prisoners were set free on account of being hopelessly afflicted with pulmonary tuberculosis. In the Illinois State prison at Joliet, during the year 1895, 39 deaths were reported from consumption; in 1900 only 8 occurred. This decrease appears to be due directly to segregation of tuberculous subjects.

Hospitals, Sanatoria, and Dispensaries.—Perhaps no country in the world can boast of better hospital facilities than our own. Indeed, many of our institutions are perfect in sanitary architecture and equipment. There are in the United States no less than 1,776 hospitals, including 35 special hospitals for consumptives; 308 sanatoria, 213 dispensaries, and over 8,000 mineral springs, of which 727 are health resorts. Unfortunately the liberality with which medical charities have been supplied has given rise to shameful abuses, and persons who would shrink from seeking charity in any other form have abused the privileges offered by hospitals and dispensaries.

Correction of Abuses: In 1896, speaking of the city of Washington, no fewer than twenty-one per cent. of the population received free medical treatment; the medical association in 1897 adopted certain rules compelling the attending staff of hospitals and dispensaries to require evidence of dependency; as a result of this system there has been a gradual but positive decrease in the number of charity patients, amounting to over nine thousand last year. It is the simplest, most just, and effective remedy for the correction of this evil.

School Hygiene.—During the year ending June 30, 1900, there were 15,341,220 children enrolled in the common schools of our country. When we consider that the mental and physical vigor of a nation depends largely on the environments of childhood and youth, it seems strange that up to within forty years little or no attention should have been paid to the hygiene of schools. The occurrence of so-called school diseases is not surprising when we reflect that children, on beginning school, enter upon a new life and environment. Up to this time they have been allowed to run and play in the open air, exercise the body and senses, without restraint, but now without a period of transition they are obliged to remain for several hours a day in close and sometimes unsanitary schoolrooms, taxing their minds and straining their eyes for near objects. Experience teaches and statistics confirm the conclusion, that quite a number of children suffer from certain physical defects and diseases, which, because rarely observed before the school period, may be justly attributed to school environments. Among the most common of these affections are myopia, lateral curvature of the spine, dyspepsia, anæmia, muscular debility, headache and nose-bleed, nervous affections, and tuberculosis. Ware, of our own country, as early as 1812 called attention to the fact that myopia was most frequently developed in the schoolroom, and during the past forty years we have been enlightened as to the cause of this and other defects, and many excellent monographs have been written on the construction of school buildings, arrangement of recitation-rooms as regards light, ventilation, adjustable seats and desks, proper type for text-books, and more rational methods of mental and physical training. This, together with a commendable zeal on the part of the authorities to correct existing evils, has resulted in many reforms, the fruits of which are already apparent in a decrease of the diseases referred to.

Medical Inspection: I cannot enter into details concerning the prevention of the spread of infectious diseases among school children, but desire to emphasize the necessity for medical inspectors, whose duty it should be to visit the schools, examine pupils, and give such directions as will reduce the dangers of spreading contagious diseases to a minimum; they should also make sanitary inspection of the buildings and present such recommendations as are necessary in the interest of the health of both and pupils and teachers, and as the physicians were perhaps the first to recognize the fact that "the system of education should be made to fit the child, not the child the system," the teachers may derive much aid from such consultations. Among the cities that have inaugurated such inspections since 1894 are Boston, New York, Brooklyn, Chicago, Milwaukee, Louisville, St. Louis, Philadelphia, Jersey City, Brookline, Mass., Buffalo, Minneapolis, and Salt Lake City, and they have proved of inestimable value.

Smallpox and Compulsory Vaccination.—In this connection, attention is invited to the undue prevalence of smallpox in the United States; the total number of cases reported to the United States Marine-Hospital service during the past fall and winter, up to March 29th, was 11,964, as compared with 7,279 cases for the corresponding period of the preceding year, and it is doubtless due to neglect in vaccination. Dr. Abbott estimates the vaccinated portion of the inhabitants of the United States at not far from ninety per cent., and the revaccinated portion at probably fifty per cent. With the introduction of glycerinated animal lymph every vestige of prejudice against vaccination should cease, and compulsory laws should be enacted in every State, so that smallpox here, as in the German army, may become practically unknown. While quite a

article on betterment of industrial conditions, showing what has elsewhere been accomplished, every effort being in the right direction, except that free medical attendance is being furnished by certain companies, involving a contract system with physicians, which ought never to gain a foothold on American soil, because it has proved a bane to the profession elsewhere.

number of States have enacted laws requiring that unvaccinated children shall not be admitted to the public schools, it is believed that these laws are not rigidly enforced.

Venereal Diseases.—A careful perusal of Dr. Prince A. Morrow's article on the "Prophylaxis of Venereal Diseases" (*Phila. Med. Jour.*, April 6, 1901) should stimulate our efforts in the prevention of diseases which affect not only the offender, but innocent wives, the offspring, and not infrequently even the medical attendant. According to Fournier, one-seventh of the population of Paris is syphilitic, and Morrow, from statistics gathered in New York, believes it is quite possible that Fournier's figures, with some modification, may apply to New York. Neisser holds that gonorrhœa is, with the exception of perhaps measles, the most widespread of all diseases. Other German authorities have computed that fully three-fourths of the adult male population and one-sixth or more of the adult females have contracted gonorrhœa; that eighty per cent. of all deaths from disease of the uterus and its adnexa are of gonorrhœal origin, while blennorrhœa neonatorum contributes a contingent to our asylums for the blind estimated at from ten to twenty per cent.—from forty to sixty per cent. before the Credé method was instituted, not to mention the destructive effects on the procreative functions. Dr. S. M. Burnett, of Georgetown University, believes that fifteen thousand of the fifty thousand blind persons in the United States lost their sight from this cause, which according to his calculation involves a financial loss to the commonwealth of seven and one-half millions annually.

The measures which have been proposed for the control of the social evil and the prevention of its consequences are numerous enough, but not so easy of practical application. On the whole I believe the remedy lies in public education, and the task as usual falls on the medical profession, especially the trusted family physician. Public lecturers on the purity of man commit a serious mistake, however, when they picture the consequences of the social evil, without offering a suitable remedy. We should make a strong plea in favor of continence, and tell our young men that while the sexual passion is very strong it can be accelerated or delayed, excited or lowered by the influence of the will. We should assure them that by the cultivation of pure thought, removal of temptation, normal mental and vigorous physical exercise, continence may become not only possible but easy. And we can hardly go astray if we follow Dr. Parkes in advising a pure young man to make his home after the age of twenty-one, and thus secure himself both from the temptations and expenses of bachelorhood.

The Management and Control of Infectious Diseases.—It is the field of infectious diseases where preventive medicine has achieved and doubtless will continue to achieve its greatest triumphs, and there is ample room, when we consider that during the census year of 1890 there were not less than 102,199 deaths from consumption, 74,496 from pneumonia, 74,711 from diarrhœal diseases, 41,677 from diphtheria, and 25,058 from typhoid fever. In spite of centuries of groping after facts, we knew nothing of the real nature of infectious diseases until the middle of the present century, and even twenty-five years ago the text-books still discussed the subject of miasma and contagia, whose nature had never been demonstrated to our senses. With improved microscopic lenses and the development of bacteriology, more especially the discovery of the anthrax bacillus by Davaine, Pollender, and Brauell (1849–1855), scientific medicine had its birth, and to-day we know that such diseases as tuberculosis, glanders, leprosy, cholera, erysipelas, wound and puerperal infections, gonorrhœa, pneumonia, cerebrospinal meningitis, typhoid fever, diphtheria, malaria, influenza, dysentery, bubonic plague, and possibly carcinoma are caused by living organisms, capable of reproduction within and without the body, and this is a strong argument in favor of the microbic nature of other infectious diseases, in which the specific organism has not yet been isolated.

The eradication of preventable diseases is the highest aim of scientific medicine to-day. The public should be made familiar with the nature and causes of infectious diseases, and be taught that many are a source of danger, against which it is entitled to be warned by proper notification through the health officer. This notification should be made compulsory in cholera, yellow fever, smallpox, chickenpox, typhus and typhoid fever, diphtheria and membranous croup, scarlet fever, tuberculosis, cerebrospinal meningitis, leprosy, glanders, bubonic plague, whooping-cough, and measles. And let me say that a prompt and correct diagnosis is the first and most important step in preventive measures. The health department should have competent medical inspectors and a clinical laboratory for the verification of the diagnosis, and have the power in certain of these diseases to display warning signs, enforce isolation and disinfection, and to take such other steps in the way of immunizing agents as may be deemed necessary to limit their spread.

Isolation, to be effective, should extend to all persons who have come in intimate contact with the patient, but this is rarely enforced except in smallpox, in the case of the attending physician, and the wage earners of the family, but it is clearly their duty to take special precautions in the way of clothing and personal disinfection. Matters of this kind ought never to be left to the discretion of the family nor the attending physicians, for even members of the profession often entertain widely opposing opinions on the subject of quarantine and disinfection, but the principles which ought to be carried out, apart from being a matter of conscience, should be accepted in a practical sense and embodied in effective laws.

Disinfection: Scientific disinfection had its inception with the labors of Koch and Sternberg some twenty years ago. Although, as we have seen, certain physical and chemical agents were used empirically for ages, now we know from laboratory experiments that they are effective because they destroy the vitality of the germs. We also know that, in most of the contagious diseases, the infective matter is given off by the patient chiefly through the secretions and excretions, and it is evident that disinfection to be of value must be directed to these and all the media with which the patient has come in contact.

"If Certain Diseases Are Preventable, why Are They not Prevented?"—My answer is, that while every scientific physician familiar with biological research knows full well that if the methods of prevention recommended by sanitarians, including the prompt disinfection of the dejecta of every typhoid-fever patient, the expectoration and excretions of diphtheria and tuberculosis patients, for example, were adopted, these diseases would be reduced to a minimum and probably eradicated in the course of a few years. The facts are, these recommendations have not been generally adopted, because the knowledge gained by experimental medicine is not sufficiently diffused. Nor are we responsible for the fact that so many of our States still permit every charlatan to practise one of the most difficult and responsible of all professions without a uniform and rigid system of examination. However, we owe it to ourselves and to humanity to take positive steps in behalf of higher medical education and laws regulating the practice of medicine. So long as we permit the existence of irregular and incompetent practitioners, so long will

the public be deceived and will we be obliged to compete with incompetent men, and so long as we tolerate the exponents of so-called "Christian Science," osteopathy, and other quacks, infectious diseases will be spread as the result of ignorance and neglect. A strong organization, such as is proposed for the American Medical Association and the various State medical societies, will speedily accomplish this and other reforms.

During the year 1900 there were 119 regular medical schools in this country, with 1,079 female and 21,673 male students; of these 22,752 students, 2,327, or about ten per cent., had degrees of A.B. or B.L. The number of graduates last year was 4,720. The homœopathic schools had 1,584 male and 325 female students, and the eclectics 500 male and 52 female students. The number of registered physicians in the United States in 1900 shows an average for the whole of about 1 to 636 inhabitants. In 31 States and Territories, according to D. McIntyre, an examination is required, in 9 certain diplomas are accepted, all others must be examined; in 5 only a diploma is required, and in 5 the laws practically impose no restriction. In 1900 there were 150 national and State medical societies, 1,097 county and local medical societies, and 282 medical journals, of which 28 were exclusively devoted to hygiene and public health.

Forecast of the Result of the Census Work upon the Mortality Statistics.—Notwithstanding these and other disadvantages in the way of defective sanitary legislation, the American medical profession has reason to be proud of its work in the century's progress of hygiene and preventive medicine. It may be truly said that every hospital or other medical charity owes its foundation and success to the activities of the medical profession. Nay, every law inscribed on the statute books, in the interest of public health in this and other countries, is the work of our noble profession. Acting upon the lofty principle that the education and betterment of the people in sanitation are not less humane than the healing of the sick, the American medical profession has filled the measures of its philanthropy by advocating laws to "regulate the health and physical well-being of communities," and thereby lessen its own income, but the results obtained during the last ten years are sufficient recompense. By the courtesy of Mr. William A. King, chief statistician of the United States census bureau, I am enabled to give you a forecast of the result of the work upon the mortality statistics at the close of the century:

The mortality returns for the twelfth census, which relate to the year beginning June 1, 1899, and ending May 31, 1900, have not yet been tabulated in full, but sufficient progress has been made to permit a comparison of the preliminary results with the figures for 1890 for a portion of the country.

Considering these results for these States in which the returns were secured from registration records in both 1890 and 1900, there appears to have been an absolute decrease in the general death rate of about 1.5 per 1,000 of population. This decrease seems to be most marked in the rates due to scarlet fever, whooping-cough, diphtheria and croup (combined), typhoid fever, malarial fever, consumption, diarrhœal diseases, and diseases of the nervous system, the decrease in the mortality from diphtheria and croup amounting to more than fifty per cent. On the other hand, the rates due to carcinoma and tumor (combined), Bright's disease, heart disease and dropsy (combined), and pneumonia are apparently greater than in 1890, the increase being most marked in case of Bright's disease, carcinoma and tumor, and pneumonia.

The death rate by age periods in the registration States has not yet been computed, as the population figures are not yet available, but the effect of the decrease in the rates due to the causes specified is shown by a decrease in the proportion of deaths occurring at each period up to thirty years.

The results in the decreased rate of diphtheria, croup, scarlet fever, typhoid fever, whooping-cough, consumption, malarial fever, and diarrhœal diseases are the direct outcome of preventive medicine, and are as gratifying as they are striking. We note with regret the increased rate in Bright's disease, heart disease, dropsy, and pneumonia, and may well pause to inquire whether our ever-increasing "National Drink Bill," averaging 17.68 gallons per capita, may not be a factor in the development of these diseases, especially since there is reason to believe that the habitual and immoderate use of alcohol, apart from increasing the connective tissue and causing cirrhosis, also produces fatty degeneration, especially of the heart, liver, and arterial coats, probably because it promotes the conversion of albuminoids into fats.

Without wishing to underrate the brilliant achievements in surgery of the brain, stomach, intestines, liver, gall bladder, and other abdominal organs, and even wounds of the human heart which have been successfully sutured in four of the nine cases reported, what after all are the ultimate benefits compared with the results obtained by improved methods in sanitation?

Since our knowledge of the nature of infectious diseases has been more and more defined, scientific methods for their prevention have been applied. We have learned, too, that in addition to the germ there must be a suitable soil for its proliferation, and that sanitation will not only destroy the environments for its development without the body, but also place the system in the best possible condition to resist its toxic action. The application of this knowledge has saved millions of lives besides an incalculable amount of human suffering and distress, not to mention the economic aspect of the question. When we remember all this and the fact that Jenner's discovery, at the close of the last century, of a fundamental and practical method of producing artificial immunity, has been far eclipsed in the last twenty years, and that we possess to-day not only curative but also protective sera for diphtheria, erysipelas, tetanus, plague, and possibly cholera, tuberculosis, typhoid fever, pneumonia, and a number of other immunizing agents for diseases of man and lower animals, we have reason to believe that the solution of the problem of immunity is only a question of time, and we may indeed expect great possibilities in our battle against infectious diseases.

To the solution of this problem, the labors of Salmon and Smith, Sternberg, Welch, Osler, Councilman, Reed, and other Americans engaged in experimental medicine have contributed their full share. Progress has crowned our past, we will not retrograde. Let our conduct raise no blush on the cheek of posterity. Let us hand-in-hand with heart and mind join in promoting the welfare of American medicine, until she has reached the proudest pinnacle in the world of science, until she has become the fountain-head of knowledge for the benefit of mankind. Then when at last we are called upon to pass through the portals beyond, Minerva Medica, in her sweeping robes of state, will proudly but reverently present us to the Supreme Healer of the Universe as types of the true physician.[1]

[1] In the preparation of this address I have been greatly aided by the library of the surgeon-general's office, the historical monographs on hygiene by Professor Kinkelnburg, of Bonn, now deceased, and Dr. S. W. Abbott, of our own country. I am also greatly indebted to Dr. W. T. Harris, the commissioner of education, and Dr. A. E. Miller, of his bureau. Other acknowledgments have been made in the text and are gratefully renewed.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM WOOD & CO., 51 Fifth Avenue.

New York, June 8, 1901.

ROCKEFELLER'S INSTITUTION FOR MEDICAL RESEARCH.

IT is announced that John D. Rockefeller has declared his intention of establishing an institution for medical research in New York City, and it is further stated that Mr. Rockefeller has placed at the disposal of the foundation, which is to be called "The Rockefeller Institute for Medical Research," the sum of $200,000. This amount is not intended as an endowment, but is to be spent as needed.

Such an institution as the one proposed has long been a necessity in this country. The MEDICAL RECORD has repeatedly advocated the advisability of its establishment, notably in the direction of State endowment. Medical societies in the different States have also added their endorsement, and Dr. Roosa, of this city, in an interesting and forcible article recently contributed to these columns, voiced the general professional sentiment on the subject. Up to the present time, however, no practical turn was given to these suggestions, save in the direction of establishing a State laboratory at Buffalo, which, as our readers know, has been doing such excellent work in connection with experimental studies of cancerous growths. It now remains for a wealthy private citizen to give a proper practical turn to a long-cherished scheme, and place bacteriological study in this country on a proper basis of assumed progress.

The board of directors, which is comprised of such well-known men as Dr. William H. Welch, Dr. T. Mitchell Prudden, Dr. Emmett Holt, Dr. C. A. Herter, Dr. Theobald Smith, Dr. Simon Flexner, and Dr. H. M. Biggs, is in itself a guarantee that the work of organizing and bringing to successful issue the purpose of the founder will be thoroughly performed. The directors have decided not to erect a laboratory at once, but to make use of the materials now at hand in the various medical schools of the city, and, when they deem the time is ripe, to launch out in a more ambitious manner.

The scientific men of the United States, up to the present time, have been severely handicapped in the contest for the laurels of original research, in that the money has been lacking to render them independent of the importunate calls which medical practice or teaching has imposed upon them, for it must be borne in mind that science is a hard mother and often does not give her children bread.

The founding of an endowed institution for the investigation of the unsolved problems of medical science will set free the men of the American medical profession educated in scientific lore, and will permit them to follow the bent of their minds, to the honor of their country and to the good of mankind, untrammelled by sordid considerations.

There is a feature in connection with the organization of the Rockefeller Medical Institute which strikingly illustrates the spirit animating those into whose hands the direction of the enterprise has been placed, and which should inspire confidence in their ability to carry through the project to the fullest advancement of science. This is their expressed determination to commence in a modest way; not to cater to sensationalism, but to proceed slowly and cautiously, and to build a reputation upon a sound basis by careful investigations, the results of which will speak for themselves. The example set by Mr. Rockefeller will be followed, doubtless, by rich men in other American cities, and a new era, it is hoped, will dawn for medical research on this side of the Atlantic.

INFLUENZA IN CHICAGO.

DISASTROUS to life and health as influenza has shown itself to be in all parts of the United States, in no one place probably has its effects been more deadly than in Chicago. There would appear to be a something in the climate of the great lake city, or perhaps an idiosyncrasy of its people, which renders them in a high degree susceptible to influenza. The disease has been the most prominent factor in the increase of the average mortality rate of Chicago for the past twelve years.

In 1889, when influenza made its appearance in epidemic form, the death rate of Chicago stood at 18.11 per 1,000, and rose to 23.92 per 1,000 in 1891, the total deaths from all causes in the latter year being the highest in number ever recorded in the history of the city. From that time till now the mortality rate has risen and fallen in sympathy with the rise and fall of influenza, although it is satisfactory to note that the annual death rate for the year ended March 31, 1901, was only 14.07 per 1,000.

A significant fact mentioned in the *Monthly Bulletin* of the Chicago department of health, pointing to the baleful influence of influenza, is that pneumonia has displaced tuberculosis as the principal cause of death in Chicago during the last ten years. In the previous half-century consumption had levied the heaviest toll on human life in that city, but in the decade 1891–1900 there were nine per cent. more deaths from pneumonia than from consumption.

The *Bulletin* concludes that apparently influenza has become domesticated in Chicago, and after remarking that its early recognition is the necessary first step to any restriction of its spread, deplores the fact that laboratory facilities for such recognition are not adequately appreciated.

The health department laboratory of Chicago has already done such excellent work in the line of bacteriological research that it is somewhat a matter for surprise that the profession fails to appreciate its efforts and continues to manifest indifference to the opportunities offered. "Prevention" should be the motto in the fight against disease, and precautionary measures best adapted to check its spread should be put into force at the first note of danger. The *Monthly Bulletin* asserts, with much reason for its assertion, that the way to fight influenza is through the culture tube and the microscope. This much at any rate is certain, that the more quickly the presence of the disease is detected, the better will be the chance of preventing its dissemination; and if bacteriological examination provides the most effective means of detection, then the medical men of Chicago will be acting in the best interest of the community by availing themselves of the laboratory facilities freely offered by the health department.

THE ABOLITION OF THE ARMY CANTEEN.

At the time when, through the well-meaning but mistaken efforts of members of the Woman's Christian Temperance Union, the soldiers' canteen was abolished, the Medical Record entered a protest against the action of Congress and predicted that so radical an innovation would not have the salutary effects anticipated by the women enthusiasts. The fact was pointed out that a large number of men would have alcoholic stimulants, and the only result of closing the canteens would be that they would satisfy elsewhere their appetites for strong drink. The liquors sold at the canteen were at any rate wholesome, while the stimulants retailed at the outside saloons, although doubtless sufficiently potent, possess few other redeeming properties, and certainly are calculated to do anything but good to the health of our fighting-men.

This forecast already has been verified, and, indeed, has recently received striking confirmation. Major Louis Seaman, late surgeon First United States Volunteer Engineers, read before the session of the Association of Military Surgeons a paper, the greater part of which consisted of a sweeping denunciation of the shortsighted policy of the authorities in doing away with the canteen, and which showed that the soldiers had suffered very considerably in consequence.

Major Seaman commenced his indictment of the course pursued by Congress by averring that its procedure had not been dictated by zeal for the soldiers' welfare, but had been undertaken rather against its better judgment in a servile catering for votes, and in direct opposition to the overwhelming testimony of line and staff officers in favor of the retention of the canteen.

As Major Seaman sagely indicates, when the soldier cannot obtain a glass of beer or light wine at the canteen, he generally makes for the nearest saloon, where, in Porto Rico, he is served with rum loaded with fusel oil; at home, with vile doctored whiskey; in the Philippines with vino, a sort of wood alcohol distilled from the nepa leaf, or in China with samshu, a product of rice—all rank poisons, one or two drinks of which "steal away his brains."

"At Paniqui in the Philippines during February and March, 1900, there were between seventy and ninety trials by court-martial each month; four-fifths of the offences were 'intoxication from native vino.' A canteen was established in the latter part of March. Since then and until February, 1901, there were never more than twenty trials in any month." Major Seaman sums up his arguments in favor of re-establishing the canteen thus: "When the canteen was maintained, the soldiers drank less, were under better influences, and returned sober and contented to their library and reading-room or their quarters. When the misguided enthusiasts of the Woman's Christian Temperance Union stop to reflect that the result of their influence in inducing Congress to abolish the canteen has produced an enormous increase of wretchedness in the army hospitals, and made many a husband, father, and lover the victim of a degrading disease, they may indulge in less self-congratulation and conclude to cease interfering with institutions about which they are hopelessly ignorant. The canteen was the most rational compromise that the ripe experience of the ablest officers of the army could devise."

An animated discussion followed the reading of Major Seaman's paper, and so greatly impressed were the majority of those present with the force of his philippics, that a resolution was carried to the effect that it was a mistake to abolish the canteen, and an earnest recommendation was made to re-establish it at the earliest possible date.

What is really needed in questions of this nature is the infusion of a little more rational common sense and a little less irrational, emotional sentiment.

A NATIONAL PSYCHO-PHYSICAL LABORATORY.

A movement is on foot to establish a psycho-physical laboratory in the Department of the Interior. This question has been mooted for some time, and it would appear that the project, if carried out on the lines drawn by its promoters, should be of great value as a means of precise psycho-physical and anthropological study. The aim of this suggested institution will be to collect sociological, pathological, or abnormal data, especially as found in children, and in criminal, pauper, and defective classes, and in hospitals. The scope of the work will not be limited to this field alone, but will extend to experiments peculiarly within the province of physiological and pathological experts. So much is heard of degeneracy in these days that it would be well if, in a country which, like America, contains people gathered from almost every race upon the earth, and recruited largely from the pauper, and to a lesser extent from the criminal and defective, classes, a laboratory, supported by the State, for the study of all forms of abnormality, should be founded.

Nowhere in the world can be found more varied and plentiful opportunities for this form of investigation.

The fact should be also borne in mind that the United States is behind many of the European nations in this particular and important branch of scientific research. It is therefore fitting and right that the Government should take upon its shoulders the burden of providing the means for prosecuting such investigations upon a sufficiently broad and comprehensive scale.

SURGICAL TREATMENT FOR PENDULOUS ABDOMEN.

While excessive deposition of fat may be directly due to the character of the diet and a particular mode of life, it is probable that hereditary tendencies, though an indirect, constitute yet a most important etiological factor. Such a condition may assume the form either of a generalized obesity, or adiposis, or of a localized accumulation of fatty tissue, lipomatosis, and this may be single or multiple. Both of these morbid states, though inherently benign, may, by reason of their intensity or their extent, become sources of great annoyance, if not actual menaces to life.

Fatty tumors are amenable only to surgical treatment, while the state of obesity or adiposis may at times be greatly ameliorated by appropriate dietetic treatment, rational denutrition cures, systematic physical exercise, and intelligent employment of preparations of thyroid gland, although here also surgical treatment may occasionally be required. Such an indication will sometimes be found in cases of excessively pendulous abdomen, complicated by marked intramural deposition of fat. An interesting instance of this has recently been reported by Dr. Lindsay Peters (*Annals of Surgery*, March, 1901, p. 299). The patient was an extremely obese woman, thirty-two years old, with transient glycosuria apparently of lipogenic or dietetic origin. She had not been unduly stout until the age of twenty-two or twenty-three, when her breasts suddenly became large, flabby, and pendulous. These were removed several years later on account of the annoyance they caused, and were found to weigh nearly twenty-five pounds. Subsequently fat began to accumulate in the abdominal walls, which soon hung down in large folds, these folds in the erect posture covering the upper portion of the thighs and in the sitting posture reaching almost to the knees. The greatest circumference of the abdomen was 200 cm. at a level of 12 cm. above the umbilicus. The patient had not been a hearty eater, but thirst had been marked from the time the breasts began to grow excessively in size, and she drank large quantities of water. She weighed two hundred and eighty-five pounds.

The excision of an enormous crescent of abdominal skin and subcutaneous fat was proposed and assented to. Accordingly, with the patient anæsthetized and in the dorsal posture, a transverse incision, 85 cm. long, was made 13 cm. above the umbilicus, through a layer of fat 5 or 6 cm. thick, extending across the abdomen from the line of contact with the table on one side to a corresponding point on the opposite side. The fat was separated from the underlying muscle in a downward direction, and a lower transverse incision was made about 5 cm. above the line of reflection of the pendulous fold, meeting the first incision at its extremities. A great crescentic mass of skin and fat was thus freed and removed. The wound was closed by means of silkworm-gut and catgut sutures. The subsequent course of the case was uncomplicated and the sugar disappeared from the urine. The removed mass of fat and skin weighed 7,450 gm. The patient was not permitted to sit up for a month, and was discharged in good condition thirty-seven days after the operation, her weight having been reduced from two hundred and eighty-five to two hundred and twenty-six pounds. The improvement was still maintained after the lapse of two years.

News of the Week.

Our Report of the American Medical Association, which has been telegraphed in full up to the time of going to press, will, we believe, be especially valued by such of our numerous readers as are interested in the doings at St. Paul. The distance from New York was too great to trust to the mail service, and hence the entire proceedings as they now appear were duly wired up to the last available moment of publication. Appreciating the fact that this is the kind of service demanded by modern journalism, we take the greatest pleasure in giving our host of subscribers all the benefits which accrue from it.

The Improved Sanitary Conditions at Havana.—The report of Major Gorgas for the month of April shows that the death rate was 26.64 per thousand. This is the smallest death rate for April, with the exception of 1900, that has occurred since 1889. The increase is due to deaths among children under five years of age, and this is caused principally by diarrhœal diseases. In point of health Havana now compares favorably with many of the larger cities of civilized countries. Havre, France, with a population of 119,470, had for the week ending March 16, 1901, 67 deaths, which would give a death rate of 29.02; Munich, with a population of 508,445, had for the week ending March 16, 1901, 266 deaths—death rate, 27.20; Dublin, with a population of 346,128, for the week ending March 23, 1901, had 243 deaths—death rate, 36.51; Kingston, Jamaica, with a population of 46,542, for the month ending March 31, 1901, had 186 deaths—death rate, 47.95. The condition of the city with regard to yellow fever is most encouraging, there having been but two cases of yellow fever and no deaths. This is the smallest April report of which there is any record. From March 8th to April 20th, a period of forty-three days, there were no cases. In 1900 the longest period was from March 26th to April 1st, both inclusive, seven days. As the population subject to yellow fever is considerably larger now than at that time, this indication is very favorable. Dr. Gorgas thinks it also shows that the measures recently inaugurated, with regard to killing mosquitos in and about the infected area, are having good results. The report

for contagious diseases shows no smallpox in the city, the last case having occurred in July, 1900. The amount of sanitary work continues large. The department is not now doing as much cleaning of houses with its own force as formerly, about two-thirds of the men having been transferred to the mosquito brigades. They are employed in cleaning out the various ditches and streams where stagnant water is found, and putting kerosene oil in all of these places. During April about twenty thousand houses were gone over in this manner. A little oil is placed in every receptacle containing standing water, and about an ounce into every closet and sink in the houses having water connections. Nearly every house in Havana has a cesspool, and these cess-pools are ideal breeding-places for mosquitos. The oil in this way runs into the cesspool and kills the larvæ. Dr. Gorgas says he has recently examined several of the main sewers that empty into the bay, and has seen a large number of larvæ floating out, showing that a considerable number are being killed by this method. If any argument were needed to show the folly of the Cuban Constitutional Convention in seeking to annul the sanitary clause of the Platt resolutions, the wonderful regeneration of Havana under Major Gorgas' masterly administration furnishes an all-sufficient one.

Association of Military Surgeons of the United States.—The annual meeting of this association was held in St. Paul on May 30th and 31st, and June 1st, under the presidency of Dr. A. J. Stone. The convention was called to order by Brig.-Gen. John F. Fulton, and after prayer by Archbishop Ireland addresses of welcome were delivered by Governor Van Sant and Judge E. A. Jaggard. On recommendation of the special committee appointed for its consideration, the resolution presented at the session of last year, amending the by-laws so as to admit ex-Confederates to membership, was adopted. Among the papers read were: "Treatment of Gunshot Wounds of the Abdomen," by Lieut.-Col. J. Van R. Hoff; "Varicocele, is it Properly a Disability from Enlistment?" by Major Bradley; "Appendicitis," by Gen. J. D. Griffith, and "Observations in China and the Tropics on the Canteen and on the Army Ration," by Major L. L. Seaman, late surgeon of the First United States Volunteer Engineers. The following resolution, presented by Dr. Seaman, was unanimously adopted:

"*Whereas*, The Association of Military Surgeons of the United States, now in session at St. Paul, recognizes that the abolition of the army post exchange or canteen has resulted, and must inevitably result, in an increase of intemperance, insubordination, discontent, desertion, and disease in the army; therefore be it

"*Resolved*, That this body deplores the action of Congress in abolishing the said post exchange or canteen, and, in the interests of discipline, morality, and sanitation, recommends its re-establishment at the earliest possible date."

It was ordered that a copy of Dr. Seaman's paper be sent to every member of Congress and to each officer of the Woman's Christian Temperance Union. The following officers were elected: *President*, Lieut.-Col. John Van Rensselaer Hoff, medical department, United States army; *First Vice-President*, Brig.-Gen. R. A. Blood, Massachusetts volunteer militia, retired; *Second Vice-President*, Surg.-Gen. Walter Wyman, United States Marine-Hospital service; *Secretary*, Major James E. Pilcher, United States army, retired; *Treasurer*, Lieut. Herbert A. Arnold, assistant surgeon, Pennsylvania National Guard, re-elected. The determination of the time and place of the next meeting was left to the executive committee.

"**Vratch.**"—The types made us say last week that this leading Russian journal had been in existence seventy-one years. It was founded twenty-one years ago by the late editor, Dr. Manasseïn.

The Maine Medical Association.—The forty-ninth annual meeting of this society will be held in the common council chamber, City Building, Portland, on June 12–14, 1901, under the presidency of Dr. Edward H. Hill, of Lewiston. The corresponding secretary is Dr. C. A. Peaslee, of Wiscasset.

The American Medico-Psychological Association.—The fifty-seventh annual meeting of this society, formerly known as the "Association of Medical Superintendents of American Institutions for the Insane," will be held at the Hotel Pfister, Milwaukee, on June 11–14, 1901, under the presidency of Dr. P. M. Wise, of New York. The secretary of the association is Dr. C. B. Burr, of Flint, Mich.

The Jamaica Hospital has hitherto had a mixed staff of ten physicians, seven regulars and three homœopaths, but the incongruity of this recently struck the board of managers and the homœopathic members of the staff were requested to resign. They did so, but it is said that there will be some strong protests against the action of the board on the part of friends of those who resigned.

The Indiana State Medical Society.—The fifty-second annual meeting of this society was held at Great Bend on May 15th, 16th, and 17th, under the presidency of Dr. G. W McCaskey, of Fort Wayne. The title of the president's address was "Physiology the Basis of Chemical Medicine: A Plea for Scientific Method." Dr. John A. Wyeth, of this city, delivered by invitation an address on "The Making of a Doctor." The officers elected for the ensuing year were: *President*, Dr. A. W. Brayton, Indianapolis; *Vice-President*, Dr. J. B. Berteling, South Bend; *Secretary*, Dr. F. C. Heath, Indianapolis; *Assistant Secretary*, Dr. W. H. Gilbert, Evansville; *Treasurer*, Dr. A. E. Bullson, Fort Wayne. The next meeting will be held at Evansville.

The Hospital Graduates' Club.—The annual dinner of this society took place at the Hotel Manhattan on the evening of May 23d, Dr. William Kelly Simpson presiding. A number of songs were well rendered by Messrs. Myles Bracewell, A. Hobart Smock, Paul Dufault, and A. J. Watrous, accompanied by Mr. Clarence Reynolds. Addresses were made by Judge Sweazey, of Newark, Mr. Martin Littleton, of Brook-

lyn, and Drs. G. E. de Schweinitz, of Philadelphia, and J. D. Bryant, E. G. Janeway, William K. Otis, and James E. Newcomb, of New York. There was an unusually large attendance of members and their guests.

The Late Dr. Conrad Wienges.—At a meeting of the attending staff of Christ Hospital, Jersey City, on May 24th, the following minute was adopted:

"We the members of the medical board of Christ Hospital record with sincere sorrow the death of our colleague and friend, Conrad Wienges, M.D., and in his demise the loss of a valued member, whose great interest in the work of this institution, and whose kindly and genial manner has so won our confidence that we cannot but regard his departure as a sad and personal bereavement.

"In the death of Dr. Wienges we mourn a citizen of high character, one long and honorably identified with our hospital, in the records of which he will always live as a faithful, intelligent, and esteemed member of his profession.

"We, as a board, tender our heartfelt sympathies to his bereaved family, and trust that the memory of his good work may soften their great sorrow.

(Signed) "B. P. Craig, M.D., President Medical Board."

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending June 1, 1901. May 25th.—Dr. J. H. Iden appointed assistant surgeon in the navy, from May 4, 1901. May 28th.—Medical Director W. S. Dixon commissioned medical director, from April 28, 1901. Medical Inspector C. G. Herndon commissioned medical inspector, from April 28, 1901. Passed Assistant Surgeon E. V. Armstrong detached from the *Vermont* and ordered to Key West naval station for duty at Dry Tortugas. Assistant Surgeon T. M. Lippitt ordered to the Washington navy yard, June 1st. Assistant Surgeon R. B. Williams detached from duty at Dry Tortugas and ordered home, to be in readiness for sea duty. Assistant Surgeon J. H. Iden ordered to the naval hospital, Chelsea, Mass., for duty. May 29th.—Passed Assistant Surgeon J. F. Costigan detached from the *Yorktown* and ordered home; resignation to be accepted after arrival. Assistant Surgeon W. M. Garton detached from the Washington navy yard, June 1st, and ordered to the *Indiana*. Assistant Surgeon H. O. Shiffert ordered to the *Nashville*. Assistant Surgeon E. Thompson ordered to the *Solace*. Assistant Surgeon R. K. McClanahan ordered to the *Culgoa*. Pharmacist J. Cowan detached from the Manila and Cavité naval station and ordered to the naval hospital at Yokohama, Japan.

The Montefiore Home for Consumptives.—On Decoration Day the Country Sanatorium for Consumptives, which is to be conducted in connection with the Montefiore Home, was opened at Bedford. The sanatorium consists of a group of five frame buildings on a high hill near the railroad station. The administration building is in the middle and is flanked by wings on either side, which contain wards behind which are accessory buildings for kitchen and laundry. Addresses were made by Mr. Lyman Bloomingdale, Vice-President Roosevelt, and Bishop Potter. A large flag was presented to the institution by Mr. H. P. Murphy, representing Lafayette Post, G. A. R., and was accepted in behalf of the home by Mr. Henry Solomon.

The Plague in Hong-Kong. — During the week ending May 25th, there were one hundred and eighty-seven deaths from the plague in Hong-Kong, almost wholly among the natives.

Official Announcement of Rockefeller Institute.—Through the generosity of Mr. John D. Rockefeller, there has been established an institute, to be known as the Rockefeller Institute for Medical Research. The purpose of the foundation, as the name implies, is to furnish facilities for original investigation, particularly in such problems in medicine and hygiene as have a practical bearing upon the prevention and treatment of disease. The sum of $200,000 has been placed at the disposal of the board to begin the work. This is not for an endowment, but may be used in a series of years for current expenses. The home of the Institute will be in New York, although, as will be seen from the make-up of the board of directors, medical men from neighboring cities will share in its management. The board is at present constituted as follows: William H. Welch, M.D., Baltimore, *President;* T. Mitchell Prudden, M.D., New York. *Vice-President;* L. Emmett Holt, M.D., New York, *Secretary;* C. A. Herter, M.D., New York, *Treasurer;* Theobald Smith, M.D., Boston; Simon Flexner, M.D., Philadelphia; H. M. Biggs, M.D., New York. It is not intended to build at once, but with the funds placed at the disposal of the board work will be begun under its direction in several different places. The immediate aims of the board are twofold. First, to shape the lines of the work along which the Institute may wisely develop, both in contributions to knowledge and in the application of existing knowledge to humane ends. When this is done, it is felt that such local habitation as the future of the Institute shall require can be more wisely planned. The potential value of an institution of this kind and under such auspices, in medical science and in the interests of humanity, can hardly be overestimated.—L. Emmett Holt, *Secretary.*

Obituary Notes.—Dr. John L. Feeny died at his home in Stapleton, Richmond Borough, on May 31st, at the age of fifty-six years. Dr. Feeny, when fifteen years of age, entered the Seaman's Retreat Hospital at Stapleton, S. I., where he remained until he entered the medical department of the New York University, from which he was graduated in 1866. After graduating, he became the house physician of the Seaman's Retreat, where he remained until 1869, when he resigned to enter private practice. In 1870 he was appointed physician to the metropolitan police, and afterward to the Richmond County police, which position he held until the consolidation of the greater city. At the time of his death he was assistant sanitary superintendent in the Borough of Richmond.

Dr. John E. Comfort died at his home in this city on May 29th. He was born in St. Louis, Mo., October 6, 1837, was graduated from the Albany Medical College in 1864, and entered the United States army January 19, 1865, as assistant surgeon of the Sixtieth New York State Volunteers. He took part in Sherman's famous march to the sea. On July 31, 1865, he was honorably discharged. For more than thirty years he practised in this city, and served twelve years as inspector on the board of health.

Dr. Wright Lane Witham, aged twenty-eight years, of South Lebanon, O., was struck by lightning and instantly killed on Tuesday, May 21st. He graduated in the class of 1900 at the University of Cincinnati, Medical Department, and had practised at the above place about ten months.

Progress of Medical Science.

Philadelphia Medical Journal, June 1, 1901.

The Examination of the Blood in Relation to Surgery is of Scientific but Often of No Practical Value, and May Misguide the Surgeon.—John B. Deaver states that the secret of life-saving surgery is promptness in diagnosis and operation, and often the time lost in awaiting the confirmation of our opinions by the laboratory can be ill afforded by the patient. As to the question of operation in anæmia, the degree of anæmia compatible with successful surgery will vary with each patient. In a general way, high grades of leucocytosis are most commonly satisfactory signs; while they are due to severe infection, they usually mean good reaction. Moderate grades of leucocytosis, if the other signs of infection are severe, are in themselves suggestive of a bad result; if the other signs of infection are slight, a mild leucocytosis means nothing of itself. Since the degree of leucocytosis is so dependent on the amount of poison absorbed and the resistance of the patient, no judgment can be formed as to the character of the infection from the blood count. Leucocytosis is very uncommon in cancer. It will be much better surgery if appendicitis cases are promptly operated on than if time is wasted over a blood count. In cases of obstructive jaundice leucocytosis is usually, though not always, present. Many drugs, such as quinine, the salicylates, antipyrin, and morphine, have the power of producing a leucocytosis. The writer concludes: Let us have blood counts made on our patients; we have already learned valuable lessons from them and undoubtedly will learn more in the future; but let us not be drawn aside by their still uncertain evidence from the lessons learned by practical experience at the bedside.

Pityriasis Versicolor, with Special Reference to Allen's Iodine Test.—Jacob Sobel concludes that: (1) The old theory that only hidden parts are affected is no longer tenable. (2) Allen's iodine test is of marked value not only for class-room demonstration and for bringing into relief pale and hidden lesions of pityriasis versicolor, but also for differentiating parasitic or presumably parasitic skin affections from those of a non-parasitic nature. (3) Recurrences are in the main due to the overlooking and non-treatment of the suprapubic region and to the use of desquamative agents to the exclusion of penetrating ones. Both must be combined if a cure is desired. (4) Phthisical subjects, while affected in great measure on account of the hypersecretion of sweat, do not form the majority of these patients. The affection occurs in all degrees of health and disease, a marked hyperidrosis, however, predisposing toward it. (5) Children and the very old are occasionally, though rarely, attacked. (6) It may occur in all shades from a very light pink to almost coal-black (pityriasis nigra), the color being influenced by the condition of cleanliness, the circulation of the skin, the occupation of the patient, and the color of the underclothing.

The Biceps Tendon Jerk in Locomotor Ataxia.—Moses Behrend, from observations which he has made, draws the following conclusions: The ataxia in the arms is, as a rule, more marked when the biceps tendon jerk is absent. The ataxia of the arms is usually marked when the same is found in the legs. In these the biceps tendon jerk is absent. In the presence of the biceps tendon jerk with slight ataxia in the arms, ataxia in the legs is invariably well marked. Sensation is usually normal in the cases with normal biceps tendon jerk. The sensory losses are usually found when the biceps tendon jerk is absent. Arthropathies are found only in the advanced cases. Astereognosis is present only in the markedly ataxic. The loss of the sense of position is almost constant in the advanced cases of tabes. The shooting pains in the arms do not bear any relation to the degree of ataxia. Marked ataxics seldom show the loss of weight sense. The intensity of the symptoms is not dependent on the duration of the case, but rather on the extent of the sclerotic process.

Pancreatitis.—By A. W. Mayo Robson.

Medical News, June 1, 1901.

Streptococcus Bronchitis in Influenza.—F. Forchheimer believes that streptococci under certain circumstances produce a clinical picture which seems more or less characteristic. According to his experience, the influenza bacillus in influenza bronchitis disappears after a comparatively short time, having been, as it were, replaced by the streptococcus. In patients under ten years of age streptococcus infection of the bronchi with influenza is apt to take upon itself a different clinical picture than in older subjects. Pseudopertussis is, on the other hand, not rare in adults. Streptococcus bronchitis is rare after fifty years. However, this may be due to the comparatively small number of cases observed. The number of cases in this series includes twenty-four males and thirty females. As to the symptoms: Any form of influenza may be followed by this peculiar type of bronchitis. The symptoms of influenza disappear before the attack of bronchitis develops. This is nearly always the case. The attack begins rather suddenly, so that in the most common form it will be fully developed in from twenty-four to forty-eight hours. The most prominent symptom is the cough; always spasmodic, sometimes simulating whooping-cough, occurring at night as well as in the daytime, and being most annoying to the patient. From the violence of the cough there develop headache, pain in the lower thoracic region, and sometimes pain in the abdominal muscles; vomiting also occurs. Coughing is generally followed by expectoration. The pulse may vary from a slow to a rapid rate. The temperature has an abnormally great diurnal range. With proper treatment, begun at the proper time, the average duration will not exceed two weeks. The severity varies from the rudimentary to the excessively developed form. As to treatment: The writer gives quinine in attacks of respiratory influenza. When streptococcus bronchitis develops, he uses the benzoate of sodium, 1 gm. every two to four hours. When the cough is severe, antipyrin or codeine must be given. For profuse expectoration atropine or belladonna may be given. Injections of antistreptococcus serum are given in severe cases. A change of climate is beneficial. This affection is not only a local but also a general infection.

Fourth-of-July Tetanus.—H. Gideon Wells states that tetanus is endemic in Chicago, the specific organism being present in the dirt of the streets. Every Fourth of July an epidemic occurs, because these bacilli are carried deeply into wounds before wads from blank cartridges, and are then under favorable conditions for multiplication. Epidemics which always occur in other portions of the country at the same time are presumably due to the same cause. Most of the cases occur when wounds have been improperly cared for, the wads not having been removed or suitable drainage instituted. Therefore, the first indication is to secure thorough surgical cleansing and drainage of the wound, preferably and almost necessarily under an anæsthetic. As, however, tetanus sometimes occurs even in cases of well-drained wounds, and frequently follows blank-cartridge wounds, the writer thinks that such cases should receive a prophylactic dose of, say, 5 c.c. of tetanus antitoxin, as soon as possible after the wound is first seen. It seems certain that if antitoxin prophylaxis were adopted there would be no further Fourth-of-July epidemics, and this end would justify the means.

The Appearance of the Soft Palate a Pathognomonic Symptom of Epidemic Influenza.—Louis Kolipinski believes that influenza can be diagnosed with ease and certainty by observing the peculiarity of appearance of the velum palati. This has been found to be constant when the general symptoms were sufficient to make the diagnosis certain. The phenomenon consists of small convex projections of a pearly whiteness or transparency upon the mucous membrane of the soft palate. Their size is that of a grain of

sand. They are either few and confined to certain parts of the velum or its processes, or else abundantly scattered over the whole of its anterior surface. A spatula rubbed over them gives a hard, rough sensation. They are not distinguishable in obscure light. They must not be confounded with drops of mucus or saliva. Their existence is devoid of any subjective sensation.

The Use of Methylene-Blue Injections in Pleurisy with Effusion.—By Charles H. Lewis.

Gastric Ulcer and Muco-Membranous Colitis at the Paris Congress.—By James J. Walsh.

Boston Medical and Surgical Journal, May 30, 1901.

The Diagnosis and Surgical Treatment of Renal Tuberculosis.—F. Tilden Brown urges the importance of early diagnosis. Urinary analysis should be careful, and smegma bacilli should be excluded by cystoscopic ureteral catheterization. As to symptoms, a dull aching in the lumbar region is significant; equally so a more acute pain referable to the kidney or ureter. Frequency of urination does not appear until the lower segment of the ureter has a genuine tuberculous lesion, or at least marked hyperæmia and œdema. The chief objective symptoms are enlarged and tender kidney, pyuria and hæmaturia, loss of color and weight, a marked diurnal variation in temperature, a reaction to tuberculin, and tubercle bacilli in the urine derived directly from the kidney. Before proposing nephrectomy the condition of the other kidney must be carefully ascertained. Every precaution to have the patient in a favorable condition must be taken. The author reports eighteen cases of tuberculous kidney.

Asthma.—F. P. Emerson reports several cases of persistent and severe asthma. In the first case a spur was found in the right naris well back on the vomer, and was removed. Recovery followed. In the second an adhesion between the septum and turbinate was relieved and ethmoiditis cured, whereupon the asthma ceased. In a third, ethmoiditis was the cause of the trouble; in a fourth the removal of a dislocated columnar cartilage, myxomatous tissue, and two posterior hypertrophies effected a cure; and in the fifth the removal of a ridge extending back through the inferior meatus and touching the inferior turbinate was followed by the best results. The cure of the asthma did not immediately follow the correction of the gross abnormalities of the nose, but yielded to the local treatment of the ethmoiditis.

A Case of Trichinosis.—By George G. Sears.

Journal of the American Medical Ass'n, June 1, 1901.

How to Treat Muscular and Joint Sprains of Railway Employees.—H. Sneve summarizes as follows: (1) Ligaments are rarely if ever torn in so-called sprains, and are never stretched. (2) The pathology in the majority of sprains is a rupture of the areolar and connective tissue around the joint, and a contusion of the lining of the joints. (3) Immobilization of muscles is not rest. On the contrary, in all sprains the muscles should have passive exercise the first few hours and days, and active exercise after that. In the majority of cases active exercise should be instituted from the beginning. (4) The plaster casts should not be used at all, even in cases in which we have a fracture, unless it is impossible to maintain a proper position of the joint. (5) Hydrotherapy in the shape of ice applied over a wet cloth the first few hours, or in the shape of water as hot fomentations or in the Scottish douche, when we wish a stimulation, is of very great value. (6) The counter-irritation of static electricity in conjunction with massage is the best treatment for a strain. (7) The ambulatory treatment of sprains in conjunction with massage is to-day the best treatment.

Is it Possible by Proper Dietetics and Hygiene to Exterminate Tuberculosis?—J. E. Kinney believes that this can be gradually accomplished, though there are two obstacles which are almost insurmountable. The first is the fact that as a rule people are not ready, while having a fair degree of health, to make effort to preserve it. Those who have not suffered are not willing to be taught, and so will not readily co-operate in regulating the conditions which have to do with their own health, or the health of their children, until they become ill. Secondly, the poverty of many in small communities, and of the masses in the large cities, does not permit such food and shelter, air and exercise as are required to produce healthful physical conditions. But each one must answer the question for himself, and as he thinks so will he work, and as he works so will the cause be hastened or retarded, for according to our present knowledge it depends not on any climate and its influence, nor on any community and its sanitation, nor on any one person and his work, but on the united efforts of all in every community.

Movable Kidney; its Cause and Treatment.—M. L. Harris draws the following conclusions from a careful study of this condition and an elaborate series of body measurements: (1) The essential cause of movable kidney lies in a particular body form. (2) The chief characteristic of this body form is a marked contraction of the lower end of the middle zone of the body with a diminution in the capacity of this portion of the body cavity. (3) This diminution in the capacity of the middle zone depresses the kidney so that the constricted outlet of the zone comes above the centre of the organ, and all acts, such as coughing, straining, lifting, flexions of the body, etc., which tend to adduct the lower ribs, cause pressure on the upper pole of the kidney and crowd it still further downward. (4) It is the long-continued repetition, in a suitable body form, of these influences, which collectively may be called internal traumata, that gradually produces a movable kidney. (5) A distinctly movable kidney is never the immediate result of a single injury or external trauma.

Antipneumococcic-Serum Treatment of Pneumonia, with Report of Cases.—G. E. Tyler reports six cases. In addition to the serum the ice-pack was employed together with alcohol, strychnine, digitalis, and oxygen, according to the indications in each individual case. Five patients recovered and one died. The author believes that if fresh serum be given in large quantities before the advent of the pneumococcus into the blood it will prevent the development of the toxic symptoms. It is exceedingly doubtful whether antipneumonic serum has any effect on the condition of the affected lung. The exudate is extra-circulatory, the vascular supply being cut off. It is therefore almost inconceivable that the serum should have any effect on it, except possibly to prevent the involvement of new areas. But if we have a serum which prevents and combats toxæmia, that is a great advance.

On Theories of Inheritance with Special Reference to the Inheritance of Acquired Conditions in Man.—J. G. Adami, speaking of the indirect transmission of acquired diatheses, says that acquired disease and the effects caused by disease cannot in general be transmitted in such a way that the offspring presents lesions identical with those produced in the parent, though it has to be recognized that there is the possibility of modification in that offspring due to the parental disease. There is the possibility of a certain amount of transmission, not of the identical local lesion caused by the disease in the parent, but of a modified or impaired condition of the germ plasm. We must recognize that constitutional disease, by leading to disturbance in the activity of important organs, tells not only directly upon these organs, but secondarily upon other organs. It leads, for example, to an altered condition of the blood and so to altered nutrition of all the cells of the body. Among other cells, the germ cells may be directly affected, their idioplasm modified, and the offspring directly influenced. Conditions affecting the parents are capable of influencing and modifying the descendants. It is this which is forcibly brought home to us in our medical work. It is changes of this order which are almost inevitably neglected by the biologists, for they are not within their ken. The changes brought about in the tissues by what is essentially chronic intoxication may be so slight as to be inappreciable. Microscopical examination may reveal nothing; only by their physiological effects can their existence be recognized. It is in the study of these conditions and their effects that medicine can afford the most valuable aid in the matter of inheritance.

Muscular Action of the Arterioles.—By A. H. Smith. Physiologically, the entire arterial system is only a continuation of the left ventricle. The blood is forwarded by the contraction of each muscular segment in the arterial wall, the segment just in advance of the current relaxing and then contracting, analogous to the action of the œsophagus with reference to the passage of food. The value of this adjuvant apparatus for the propulsion of the blood is at once evident. Calcification destroys the elasticity of the vessel and makes its walls rigid. The mechanical obstacle which this condition necessarily presents to the forward movement of the blood is of the first importance, and this is enhanced when fibrosis of the outer coat is added. But in the latter case the effect goes beyond the mere impairment of elasticity. The delicate fibres of the vasomotor system distributed to the muscular coat are stretched

and compressed by the greatly thickened and condensed outer coat through which they pass. In this way the innervation is impaired or, it may be, cut off at certain points. The resulting impairment of muscular action throws just so much more labor upon the heart, which in pronounced cases is compelled to force the blood unaided through the entire round of the circulation. That hypertrophy of the ventricle should follow is only an illustration of a general law proportioning muscular growth to muscular activity.

American Medicine, June 1, 1901.

The Recognition of Tabes Dorsalis.—Theodore Diller believes that the following symptoms are the cardinal ones of tabes, named in the order of their importance: (1) Failure of knee jerks; (2) Romberg symptoms (swaying with eyes closed); (3) Argyll-Robertson pupil; (4) lightning pains; (5) Loss of functions of the bladder or sexual organs. The writer believes that with the presence of any three of these symptoms, the diagnosis may with certainty—and in the presence of any two, with probability—be made, when evidence pointing to multiple neuritis, paralytic dementia, or cerebrospinal syphilis is absent. Among the important secondary symptoms or signs are: (1) Paræsthesia, anæsthesia, or analgesia of the legs; (2) locomotor ataxia; (3) transient ocular palsies; (4) paræsthesia in the ulnar distribution; (5) optic atrophy. With the presence of two of the cardinal signs of tabes and one of the secondary signs, the writer believes the diagnosis may be made with certainty; and made as most probable with the presence of two of the secondary and only one of the primary symptoms; and, indeed, it may be made with certainty in the absence of all the cardinal symptoms. Many combinations of symptoms are, of course, seen in tabes, and the evidence presented by each case should be carefully weighed. When this is done, it will happen but rarely that the diagnosis cannot be made with certainty or probability.

The Lancet, May 25, 1901.

Acute Colitis in Children.—E. Cautley records the history of an epidemic of this affection recently occurring in a London tenement district. Out of thirty children in the locality six were attacked, and of these six, four died; of thirteen women in the same families, three were attacked severely but all recovered. This type of colitis seems to be less common in England than in America (if the writer can be believed). No source of infection or sanitary defects could be ascertained. Without doubt the poison was of a bacterial nature. The bacillus enteritidis and bacillus coli communis were found, but the disease could not be definitely ascribed to either of them. The onset was sudden, with vomiting, diarrhœa, and fever. The stools were green, small, very frequent, and contained mucus and bright red blood, but little or no fecal matter. The eyes were sunken, faeies anxious, and the whole condition suggestive of great prostration. The best therapeutic results came from eocaine, in minute doses, for the vomiting, and salicylate of bismuth for the diarrhœa.

Two Cases of Carcinoma Treated with Cacodylate of Soda.—By E. M. Payne. Case I. was that of a woman aged forty-five years, with uterine cancer. Injections of the cacodylate of soda were commenced, the dose at first being 2 egm., gradually increased to 7.5 cgm. Injections were made daily. All symptoms ceased, and the patient became so much better that she refused further treatment. Case II. was that of a man aged seventy years, with cancer of the tongue. Similar injections were given and marked improvement followed. The author realizes that these two cases are not conclusive, and does not claim that the remedy is a cure, though he does believe that it is a valuable palliative.

Ruptured Inferior Vena Cava; Vitality After Severe Injury.—A. Caddy reports the case of a boy of eight years who was run over by a wagon. The interest of this case lies in the fact of the boy's power of living after such extensive injuries for two and a half hours, excluding the time required to bring him to hospital (twenty minutes). The injuries included the rupture of the largest systemic vein of the body, laceration of the lung, and bruising of the left ventricle of the heart.

A Rare Cause of Sudden Death.—G. H. Metcalfe reports a case of sudden death supposed to be due to the impaction of a piece of orange in the trachea. Autopsy revealed the trachea blocked by pieces of caseous glands. On the right side, half an inch above the bifurcation, was a round mole with smooth edges. This communicated with a sac containing caseous matter similar to that found in the trachea.

British Medical Journal, May 25, 1901.

A Case of Almost Universal Ankylosis.—T. K. Monro reports this case. The patient was an iron-turner, and was eighteen years of age when the articular affection began. He would not wear flannels, and often became wet on going to and from his work. The first symptom was extreme pain in the left hip. After being rubbed in the morning he was able to go to work. Severe pains would run down the left leg from the hip. After two years he had to give up work on account of the pain in almost all the joints of the lower limbs and in the back, especially the back of the neck. As a rule, the disease in each joint began with pain, which was soon followed by swelling and finally by fixation. The greatest pain was in the knees. From the age of twenty-two till his death, at forty-six, he was completely bed-ridden. His legs would jerk terribly, especially just as he was falling asleep. Generally, a joint ceased to be painful only after its fixation was complete. Gradually his jaws became set, and he was fed through an orifice caused by the falling out or breaking off of two teeth. He had some toothache. He finally lost the sight of the right eye through the development of an acute iridocyclitis, atrophy of the globe, and subsequent ossification of the choroid. Breathing was chiefly abdominal. Sensation was unaffected. There was no ataxy in the early stages. Till the very last, when there was retention of urine, there was no disorder of micturition. He never lost control of the bowel. The skin remained sound. The lower limbs became fixed years before the upper limbs. The right arm was the last to be disabled. The patient generally slept about six hours out of the twenty-four, but he wakened two or three times an hour. Intelligence was perfectly preserved. His hearing was good. He was quite cheerful. There was a systolic murmur at the apex and base of the heart. There was no rheumatism in the family history. His last illness began with pain in the left side and cough. Death took place apparently through accumulation of bronchial secretion. This affection appears to correspond to the subacute type of the very rare disease described by Griffiths as "universal bony ankylosis or arthritis ossificans." Suffers from this affection are popularly known as "ossified" men.

A Method of Sterilizing Soft Catheters.—Herbert T. Herring has for some years given up the use of all chemical antiseptics, relying entirely on heat applied by means of water as the best agent to produce an aseptic condition in both instruments and lubricant. Experiments on this subject were conducted by William G. Savage. The catheters were soaked in a mixture of bacillus coli and staphylococcus pyogenes aureus. They were then put into water at the required temperature for the time given. Then inoculations were made from their interior on to agar smears, which were cultivated at 37° C. Previous to each batch of experiments controls were made by cultivating from the catheter immediately before it was put in the hot water. In every one of these cases copious growth resulted. Wa-

ter at 150° F. (65.5° C.), even for half a minute, is a reliable sterilizer of catheters for ordinary work—that is, it will not in this time kill bacteria with spores, but these are not likely to be met with. The writer believes that this method is not more destructive to catheters than any other method of rendering them aseptic.

Case of Cancer of the Larynx with a Long Course.—E. Donaldson observed this case for the first time two years after its commencement. It lasted nine years and one month. Hoarseness was first complained of. There was discovered by laryngoscopical examination a sessile warty growth at the anterior part of the left vocal cord. It was removed with forceps and examined microscopically. The pieces removed were non-malignant. In two years the hoarseness returned, the wart this time occupying nearly one-third of the cord. Two years later a growth appeared on the right cord. The growths were touched with ethylate of sodium, absolute alcohol, and chloride of zinc solution. Four years later tracheotomy was performed. The condition of the larynx became progressively worse. The patient emaciated rapidly toward the end and died of exhaustion. Post-mortem examination showed the growth to be an epithelioma. Whether this growth was malignant at the beginning or became so during the course of the affection is left to the reader's judgment.

Furunculosis of the External Auditory Canal Simulating Mastoid Periostitis.—James Galbraith Connal states that it is extremely difficult in some instances to distinguish between mastoid periostitis and œdema over the mastoid arising from a furuncular inflammation in the external auditory meatus. The difficulty is increased if there is a coexisting purulent otitis media. A thorough inspection of the external meatus should be made, when the presence or absence of a localized furuncular swelling with its attendant sensitiveness to touch will probably settle the diagnosis. A case cited is that of a boy aged eight years. He had for eight days complained of deafness and great pain in the right ear. He could not sleep at night for the pain. Previously, he had been strong and healthy. Examination showed two furuncles. There was marked swelling over the mastoid with œdema of the eyelids on the same side. The furuncles were incised. The pus showed a pure culture of the staphylococcus aureus. Eight days later the boy was quite well.

Veld Sores.—N. Bishop Harman thinks that veld sores are due not to any novel specific organism but to the staphylococcus aureus, which has become attenuated in its virulence and by a process of adaptation has gained a peculiarly powerful resistance to destruction. It produces its effects among unwashed folk whose resistance is diminished by long feeding on preserved foods. These sores are more frequent among mounted men than among infantry, since the former are more liable to abrasions in the handling of their harness, etc. The infective organism of the "Natal sore" is the same as that of the veld sore, but the conditions are different. The veld sore arises primarily within the deep layers of the epidermis, which it lifts to form a bleb; while the Natal sore arises beneath the true skin, and its discharge is more purulent.

Suprarenal Extract in Prostatic Hemorrhages.—W. Habgood describes a case in which he gave suprarenal extract for prostatic hemorrhage. In a few days the hemorrhage lessened and after some weeks nearly disappeared, but such a degree of palpitation was induced that the patient could not take his usual exercise. When the extract was stopped, the palpitation ceased. Again hemorrhage occurred, the extract was given, and palpitation developed. The writer fears to use the treatment any further in this case.

A Case of Eclampsia.—By E. J. W. Carruthers.

French Journals.

Rôle of the Lymphatic Ganglia in Infection and in Cancer.—Courtois-Suffit states that the lymphatic ganglia offer an organ of resistance to bacteria: By retaining in their course bacteria which have not been destroyed at the point of inoculation and which have escaped the action of the leucocytes and of the endothelium in the passage through the lymphatic vessels, and by attenuating their virulence. It has been proved that bacteria which have penetrated the ganglion are less virulent than those which have been isolated at the point of inoculation; in the normal state the ganglion plays the rôle, by means of its endothelial or its mononuclear cells, of massing together waste matter which circulates in the lymph (débris of hæmatin, of leucocytes, fragments of nuclein); during the course of an infection this rôle continues and assumes considerable importance. Besides the phagocytic rôle, the ganglion produces leucocytes which pass into the lymphatic system and especially into the general circulation. Physically, chemically, and anatomically, the lymphatic ganglion represents in the animal economy a true differentiated organ, whose function is to protect the organism against both the microorganism and its toxins. Cancerous ganglia are generally hypertrophied. At first they are movable, but they soon mass together on account of the cancerous or inflammatory periadenitis. There is a theory that the ganglionic tumor reproduces not only the histological type of the primitive tumor, but often also its most trifling characteristics. When the ganglion becomes cancerous, this condition remains for some time, the ganglion playing the rôle which it does in other infectious processes; but, finally, the ganglion ulcerates and becomes little by little destroyed, and thus a new centre of dissemination is created. When all the ganglionic barriers are destroyed, the cancer becomes generalized by the blood-vessels and is disseminated to the different organs.—*Le Bulletin Médical*, May 18, 1901.

Mercurial Injections in the Treatment of Syphilis.—Emery, in discussing this subject, speaks of the method of intravenous mercurial injections. This method is still in its infancy, although it is already several years old. The preparation which has been employed so far is the one-per-cent. aqueous solution of cyanide of mercury. The daily dose is 1 c.c., or 1 cgm. of the salt. The injection is made in one of the superficial veins of the arm. The needle is directed very obliquely into the vein and the liquid slowly injected. The point of injection is covered with a bit of cotton applied with collodion. Abadie has used this method for some years in ocular syphilis with the happiest results, certain troubles which had proved refractory to calomel yielding to the treatment.—*La Médecine Moderne*, May 15, 1901.

Abdominal Massage; its Indications in Gastro-Intestinal Dyspepsias.—F. Cantru, at the end of his discussion of this subject, which is quite detailed, speaks of the very beneficial effects of abdominal massage in constipation. In certain cases this method of treatment is followed by the most rapid results. In other cases the method has to be combined with other measures, such as electricity, the use of mineral waters, etc. However, in every case the true cause of the constipation must be discovered if the best results are to be attained.—*Journal des Praticiens*, May 18, 1901.

Deutsche med. Wochenschrift, May 9 and 16, 1901.

Concealed Gastric Hemorrhages.—I. Boas says that bleeding from the stomach occurs in two forms: either copiously in well-marked hemorrhages, or in minute quantities coming from capillaries, ulcers, or ulcerating growths. In either case the normal color of the vomited blood may be preserved or the material may present the well-known coffee-grounds appearance. If the quantity of blood lost is very small, no appreciable change is produced in the stomach contents, especially if the reaction is very acid. A large number of test meals examined by the author, even to the most careful scrutiny, revealed nothing suspicious, and yet there were more or less noteworthy quantities of blood. In testing, Weber's guaiac reaction is the most satisfactory, and if care is taken to use only a fresh tincture it exceeds all the other chemical, spectroscopic, and microscopical tests in delicacy. Material for such examination is preferably to be obtained by the careful use of the stomach tube, since vomitus is likely to contain traces of blood from the mouth, pharynx, or œsophagus. An analysis of eighty-three cases of stomach disease in which the presence of blood was searched for, permits the formation of three groups. The first gave uniformly negative results and embraces all the neuroses, gastritis anacida and subacida, hyperacidity, hypersecretion, and benign dilatation. In class two the results were not constant, blood being sometimes present, sometimes absent. These cases comprise ulcer, duodenal stenosis, syphilis of the stomach, and a probably carcinomatous stenosis of the colon. Group three was characterized by constantly positive results, and includes stenotic gastritis and carcinoma. In general it may be said that three conditions are especially conducive to the occurrence of concealed hemorrhages—viz., typical ulcer, new growths with a tendency to ulceration, and intense congestion.

The Hydriatic Treatment of Incipient Pulmonary Tuberculosis at Home.—H. Meffert says that the value of this method of treatment has been universally recognized, and describes a simple means of carrying it out in the homes of patients. The bed is first covered with a woollen blanket sufficiently large completely to envelop the patient from head to foot, and on top of this are spread two smaller blankets, one long enough to reach from the chin to the hips, and the other from there to the feet. Over these a sheet is spread and the patient wrapped up in the customary manner for a dry pack, lying quiet until thoroughly warm. The coverings of the upper part of the body are then unloosened and the arms and trunk rapidly sponged off by one or, preferably, two attendants, and the wrappings restored without drying, after which the lower extremities are similarly treated, the whole procedure not taking more than one minute. In this, which is virtually a wet pack, the patient is allowed to remain till he feels perfectly warm and dry again, when he is released and stands up by the bedside with his feet in a tub of warm water. The entire body is then showered with water from an ordinary watering-pot for a period of not more than thirty seconds, is rapidly dried, and the patient resumes his clothes. The treatment should be carried out twice a day, the first time in bed before rising in the morning, and the second time between four and six in the afternoon. The preliminary period of warming up is very necessary, as thereby all subsequent shock is prevented, and considerable care is also required in determining the temperatures of the water to be used for the sponging and showering in each case.

The Pathology and Treatment of Cicatricial Contraction of the Bladder.—D. Raskai reports a case of this affection in which the capacity of even the artificially distended bladder was only about one ounce, and there was imperative desire to micturate every thirty or forty minutes day and night, postponement of the act being followed by intense pain and involuntary discharge of the urine. Under daily catheterization with careful boric-acid irrigations and instillations of weak silver-nitrate solution the patient improved so far that after four months of treatment the pain and strangury were somewhat decreased, as well as the frequency of urination, and vesical capacity was slightly increased. Concentric hypertrophy and the so-called irritable bladder of women are the two conditions with which contracted bladder is most often confounded, and the latter of these is able to simulate almost every symptom of the organic lesion. The most valuable diagnostic point is the fact that the diminished capacity of the organ in other affections depends mainly on the irritability of the diseased mucous membrane, which makes distention ordinarily acutely painful, but not impossible during narcosis or even deep physiological sleep; while in contraction the reduction in volume is absolute, and not to be overcome by any means either natural or artificial.

The Morphology of Bacteria and its Relation to Virulence.—G. Ascoli, in discussing the significance of the Babes-Ernst bodies and other granulations found in bacteria, which numerous observers have considered as nuclear bodies, localizations of condensation products, hypochromatic substance, etc., says that the attempts at the demonstration of actual nuclei in the bodies of bacteria have as yet been unsuccessful. All the theories and observations so far made public on this subject are unsatisfactory and do not permit of any definite conclusion. The various types of granulation which have been described, in spite of chemical differences are to be looked upon as homologous structures, and while their exact biological position is still in doubt, it is probable that they indicate the termination of the vegetative state and are intimately concerned with sporulation. No positive conclusions regarding their relation to vitality and virulence are as yet possible.

Occupational Methæmoglobin Intoxications and their Treatment by Means of Oxygen Inhalations.—By H. Brat (conclusion).

The Magnet Operating Room.—By J. Hirschberg.

The Serum Diagnosis of Tuberculosis.—By E. Romberg.

Journal of Tropical Medicine, April 15, and May 1, 1901.

A Case of Acute Lymphatic Leukæmia Supervening on Malaria.—J. Preston Maxwell reports the case of a man in Changpoo, who has been under observation for the last two years with occasional attacks of malaria. After one such attack great weakness and weariness supervened. The peripheral blood contained no malarial parasites. The blood count was as follows: Red corpuscles, 1,200,000; hæmoglobin, fifteen per cent.; white corpuscles, 1-10. The latter were almost exclusively large and small lymphocytes, and the stained slides were typical of the disease known as lymphatic leucocythæmia. In spite of all treatment the patient died of exhaustion. This rare disease supervened directly upon a malarial attack, was steady in its progress, and lasted about five weeks. No rigors were noted, and bleeding was not a marked feature. The persistent depression which affected the patient was very noticeable. Without the blood examination the case might have been mistaken for malarial cachexia.

The Treatment of Chronic Granular Lids.—A. B. Dalgetty disinfects the conjunctivæ and the neighborhood of the eye with corrosive sublimate, 1:1,000, and then injects ten minims of a five-per-cent. solution of hydrochlorate of cocaine into the loose skin of the lid, rubbing the same solution into the everted and thickened conjunctiva. The eyelid is then grasped with a pair of fine-bladed forceps so as to expose the whole diseased portion; then, with a pair of scissors curved on the flat, the entire thickness of the hardened membrane is removed down to the healthy tissue beneath. When the forceps is removed, free bleeding ensues, but it is arrested at once by the perfect apposition of the eyeball. A pad of lint and bandage is all the dressing required. The lids are drawn apart and the exudation washed away with boric-acid lotion twice daily until healing takes place, usually in four days. There is no deformity of the eyelid as a result of this treatment, neither is a general anæsthetic necessary, nor slitting of the canthus.

The Etiology of Beri-Beri.—H. Noble Joynt describes an epidemic of this disease in Fiji among Japanese laborers. Out of 250 men, 226 contracted beri-beri, yet they were very cleanly in their habits. The Indian coolies lived in dark, ill-ventilated houses swarming with cockroaches, but not one of them suffered from infection. The author thinks that the conditions of heat, moisture, personal habits of crowding together, the slow beginning of the epidemic and its rapid spread as soon as the conditions became suitable, favor the generally received theory of direct infection by a slowly infective germ, introduced in this instance by a man already infected before arrival or by clothes or other belongings, and propagated by direct contact or by dwelling in a house saturated with the germs, and that these conditions negative Dr. Van Scheer's hypothesis that the cockroach is the means of propagation. Were the latter the case the Indians could hardly have escaped.

Note on the Treatment of Dysentery.—M. D. Eder, of Palmira, Colombia, does not consider milk a perfect food in this disease. He has found meat, boiled or roasted and finely chopped, to be the best food, accompanied by white of egg beaten up with sugar and water; rice and corn flour as progress is made. He does not believe in the expectant treatment as to drugs. Ipecacuanha has given him better results than the sulphates: 50 to 60 cgm. of the powdered ipecac with 15 to 20 cgm. of benzonaphthol or betol, in an emulsion every two hours throughout the day. For tenesmus and general pain morphine should be given hypodermically. For the post-dysenteric diarrhœa the most useful drug is strong lactic acid, in full doses, say 50 cgm., with a few drops of paregoric every two hours.

On Yaws Observed in Fiji.—Morgan Finucane concludes that the disease is a chronic and continuous one, and the subsequent phenomena seen in Fijians during adult and old life are sequelæ of the early infantile yaws that the race suffers from. The early infantile and late adult eruptions are polymorphous and symmetrical, more commonly presenting in early life vesicular, papular, and pustular forms, while in later life the tendency is to scaly, isolated, papular ones, psoriasis, rupial and ecthymatous sores, tubercular and lupoid forms of ulceration. The early bone pains and cachexia are similar to those noticed in early syphilis in Europeans. The author holds that greater attention should be given to the investigation of this disease by physicians and commissions.

How to Avoid Prickly Heat.—Major R. R. H. Moore considers the disease to be caused by irritation of the skin produced by a constant bath of perspiration. The remedy is to preserve nature's protective coat by abandoning the use of soap, and after the bath anointing the body with pure cocoanut oil. It should be put on with the hand, not a sponge or rag. The skin absorbs the oil, and the body can be rubbed with a towel without any of it coming off, unless an excess has been used, when the towel will remove the excess.

The Condition of the Teeth in Natives of the Tropics.—Major Buchanan reports that in Bhagalpur it is the exception to find sound and healthy teeth. The most remarkable fact is the very great contrast between the upper and lower jaws, the teeth of the lower jaw being much oftener bad and far worse than those of the upper jaw. The author considers the cause to be neglect.

Measles in the Tropics.—M. D. Eder records an epidemic in Colombia, probably introduced by soldiers returning from the coast.

OUR LONDON LETTER.

(From Our Special Correspondent.)

HOSPITAL FUNDS—PARLIAMENT: RABIES, POISONED GLUCOSE, CREMATION—CANCER OF THE STOMACH—GASTRIC ULCER AND SUBDIAPHRAGMATIC ABSCESSES—OPERATIONS FOR ASCITES—SALINE INJECTIONS IN PUERPERAL ECLAMPSIA—BRITISH MEDICAL ASSOCIATION—SIR J. WILLIAMS, DR. ALLCHIN, ETC.

London, May 17, 1901.

At the meeting of the council of the Prince of Wales' Hospital Fund last Friday it was announced that the King becomes the patron, resigning the presidency, which is taken by the Duke of Cornwall and York. The report showed an increase of £3,000 in the total receipts for the year. It was decided to award £50,000 to the hospitals and convalescent homes, to do which £2,183 has to be drawn from capital account. The appointment of visitors was considered to have produced satisfaction.

The report of the Hospital Saturday Fund for its twenty-seventh year also states that there was an increase in its total income. It was, however, small. The sum distributed was £17,698. This fund seems to have excited none of the distrust with which the Sunday fund is too often regarded.

In Parliament, in reply to a question as to rabies in the year preceding the regulations of the agricultural department, the minister stated that in 1895 there were 672 cases; in 1896 there were 438; in the year 1900 there were 6, and this year, up to May 4, there has been 1.

Attention was called to the statement that seven hundred tons of glucose contaminated with arsenic is in the hands of the liquidators of the manufacturers. Mr. Long promised that the subject would not be lost sight of by the local government board. This matter has also been before the royal commissioners, when Sir W. Church elicited important statements and promises.

The cremation bill is thought to have a good chance of passing.

The census is giving rise to some surprise as well as amusement. It will be necessary for many places to correct their vital statistics more thoroughly than they expected. The estimated rate of increase has in some been exceeded, in others not reached. There is a declining rate in most of the large towns, mostly due, no doubt, to the migration of residents to the suburbs, the demolition of crowded dwellings, and such-like causes. Substitution of business premises for dwellings has operated largely in some parts of London, and in others there has been a satisfactory migration from overcrowded localities.

At the last meeting of the Clinical Society a case of cancer of the stomach with unusual vascular and blood changes was related by Drs. Pasteur and Brice-Jones. Death occurred twelve days after admission. There had been capillary stasis in the nose and feet as in Raynaud's disease, and the blood was thought to resemble that of pernicious anæmia, but Dr. Hunter said the resemblance in these two affections was only superficial, and he mentioned some of the differences.

Dr. Norman Dalton then related a case of perforating gastric ulcer causing a sub-diaphragmatic abscess which burst through the diaphragm into the lung. While the patient, a parlor-maid aged twenty-five years, was in the hospital there was not the least sign of stomach trouble. Food was taken without causing uneasiness or pain, nor was there any cough or expectoration. All signs of fluid at the left base were present, and tapping yielded fifteen ounces of clear fluid. On the last day of her life the first sputum occurred and had a sour smell, which soon became gangrenous. At the post-mortem the true nature of the case was discovered. This is another illustration of the facts recorded about these cases. They may give rise to no suspicion of the stomach lesion, and clear fluid may be drawn off from the pleura though a foul abscess is in close proximity. Lung symptoms, too, may obscure the condition until gangrene announces the end.

Dr. L. Dickenson remarked that a little difference in the direction might have discharged the abscess through a bronchus.

Mr. Bidwell mentioned a case treated as pleurisy by aspiration. As it did not progress he resected two ribs and found an abscess which opened into the lung. Later, the patient ate some figs and the seeds appeared in the dressing. This opened his eyes. Further resection and drainage were resorted to, and the man recovered.

Dr. Hawkins mentioned another case, and referred to out-patients with dyspeptic symptoms who had later been admitted with ulcer—one case in which the pericardium had been perforated.

A paper was then read by Mr. Bidwell on cases of ascites treated by operation. He referred to the cases collected by Pachard and Lelanto and to three of his own, of which one was successful, although a complicated one. He thought the most suitable cases were hepatic, in which the liver was still enlarged, and that renal or cardiac disease need not be considered a contra-indication.

Dr. Morison questioned whether obliteration of the peritoneal cavity was altogether advantageous, and whether effusion into that space might not sometimes be beneficial. He had found that tight strapping after paracentesis prevented recurrence, and was trying to ascertain whether the tapping might not be dispensed with and the strapping alone suffice.

Other members mentioned later risks, although the operation might be practically safe. Such risks were a tendency to hæmatemesis or to poisoning by admixture of portal blood with the general circulation through obliteration of the peritoneal cavity; and hernia of the abdominal wound.

At the April meeting of the Obstetrical Society Dr. E. W. H. Groves read a paper on "Saline Infusion in Puerperal Eclampsia," the discussion on which was adjourned to the May meeting. Dr. Groves related two cases of his own and tabulated forty-seven others recorded by different observers. They gave a mortality of 12.7 per cent. He considered the efficacy of the injections to be due to their preventing the multiple capillary thrombi from forming, and also dissolving any already formed. The increased coagulability of the blood, which led to these thrombi, was attributed to toxins in the blood, and these produced the pre-eclamptic stage of the disease. The toxins might originate in the placenta, fœtus, and alimentary canal.

Dr. H. Spencer said he had tried the infusions in only two cases; but, though both resulted in recovery, he did not attribute the result to the treatment. The mortality of the disease varied greatly. He had a long series of successful cases, followed by several fatal ones. He thought morphine lessened the fits better than anything else, and its value was great though its use was not without danger. In the older cases septicæmia was included, but now they were separated, and this would vitiate statistics. He was not convinced that saline solutions had lessened the mortality.

Dr. Herman also was not satisfied with the statistics of the paper, and quoted those collected by Charpentier in his paper on chloral as giving a much lower death rate. As to the theory that the coagulability of the blood is increased in eclampsia, the only evidence offered is that in some cases the medical man had been surprised at the little blood lost. The "pre-eclamptic stage" described was the chronic renal disease of pregnancy, and not more than one in five of these renal cases suffered from eclampsia, so that the term could not be justified. In other cases eclampsia occurred without previous renal disease. He thought the morbid condition to be acute degeneration of the cells of the liver and kidneys, the thrombi being only the result of the fits.

Dr. Griffith thought it a mistake to discuss the subject under the term puerperal eclampsia, for that occurred in only a fraction of the cases of toxæmia with nephritis—the real disease. He compared eclampsia with placenta prævia, as both gave rise to great alarm and to dangerous methods of treatment. The patient's well-being was greatly increased by delivery, but the means to effect it should be safe. He feared many were victims of forced delivery, morphine, pilocarpin, and septicæmia.

Dr. T. W. Eden said that if the toxæmic theory of albuminuria were accepted, the renal and hepatic changes must be considered incidents of the disease—not its cause. The objection to this view was, to him, that it proved too much, for according to it every pregnant woman ought to be albuminuric. There must at first be deficient elimination allowing toxins to accumulate in the blood—perhaps something like the "renal inadequacy" described by Sir A. Clark.

Dr. A. Giles said primary renal disease was associated with imperfect elimination, in which other measures were preferable to saline injections. In other cases they might give good results. Injection into the cellular tissue was easier and quicker than transfusion, and might be better, as the fluid was mixed with the serum in the tissues before reaching the blood.

Dr. Jardine, of Glasgow, believed in the toxæmia theory and in the saline solutions as remedial. He gave statistics from the Glasgow Maternity Hospital, where many bad cases were admitted, often moribund. The older plans gave a death rate of forty-seven per cent, saline infusions twenty-four per cent. Personally, he had had three deaths in twenty-two cases. He used decinormal saline solution with one drachm of acetate of soda added to each pint. Diuresis was quickly established by this.

Dr. M. Kerr, of Glasgow, was equally in favor of the remedy, but rather as an adjunct to general treatment than otherwise.

Dr. A. Routh held that whatever the value of salines in pre-eclamptic states, sedatives must be relied on in the actual convulsions.

Dr. Handfield-Jones said the retention of toxic substances might produce the fits in some cases, but in others they must be due to change in the central nervous system. No doubt in some cases the injections were useful, but not in others.

The president (Dr. Horrocks) confessed he was not convinced that the treatment was a remedy for eclampsia. We had already many remedies, or, at least, modes of treatment, and that meant there was no known cure. Pilocarpin was at one time given in all bad cases, and he thought it valuable, but it must be carefully used. It had not fulfilled expectations, and perhaps saline fluids may not. These it seemed to him better to inject into the cellular tissue rather than into the veins in these cases, as there was no hemorrhage, and so no underfilling of the vascular system. If it were true that diluting the blood was the object, then venesection should be performed and the saline injected into the rectum and cellular tissue.

The King has consented to be patron of the British Medical Association. You may remember his majesty was made honorary member when Prince of Wales. The Metropolitan Branch is issuing invitations to a *conversazione* at South Kensington.

Sir John Williams is the new crown member of the Medical Council.

On Monday the officers for the ensuing year were elected by the Medical Society of London. Dr. Allchin is the new president, and Mr. J. Hutchinson, Jr., takes the vacant honorary secretaryship.

GENERALIZED GONORRHŒAL INFECTION.

To the Editor of the Medical Record.

Sir: In your editorial of May 18th, entitled "Generalized Gonorrhœal Infection," after a fair statement of the cardinal facts concerning infection by the pathogenic organisms, you say: "We thus have to do with two principal conditions: (1) Infection, which may be local or general; and (2) intoxication." You also suggest bacteræmia as a synonym for the general infection, and you assert that these terms are sufficiently descriptive and comprehensive, and should displace others such as septicæmia and pyæmia. Will you allow me to differ from this opinion and present the reasons for such difference?

Infection can only mean the reception of an organism into some portion of the animal body, and its colonization at such point of entrance, therefore all infections, taking place naturally, must be primarily local. In some instances the colony remains permanently localized, in others some members of the colony pass into the general circulation. No allusion is here intended to artificial inoculations from whatever cause, only to natural infections due to the inherent powers of the invading organism.

There are therefore two factors in a natural infection, the invading organism and the animal body invaded. It must rest, therefore, that all phenomena connected with such an infection depend upon the potentials inherent in the germ and those inherent in the animal body. It would seem, therefore, that our nomenclature must depend upon our knowledge of these potentials.

Infection is a very general term; one may be infected by an absolutely harmless germ, as with colon or proteus organisms in the alimentary canal, or even with pathogenic organisms producing, under certain conditions, no deleterious results from even a considerable colony. The term, therefore, only indicates the presence of a colony of any certain germ.

With such colonization the development of the potentials of the germ commences, and now it is that we have the origin of the second term which you use, "intoxication."

Intoxication is the expression of the reaction of the animal body to the development of the germ potential of toxicity, or poison production. With the natural infective organism this expression is remarkably constant; the symptoms being nearly the same in all cases of the same disease, showing the development of a potential in each organism specifically defining its influence upon the animal body, they are specifically potential. Each of them, like giant powder, is potentially harmful, but each must be brought under environment suitable for the development of this potential before harm may result. In other words the bacillus diphtheriæ is specific and harmful in only a throat or other environment suitable for its potential development, and it is not specific actually in the agar-agar tube. Nor is it specific or harmful in a throat environment unsuited to the development of its potential forces.

Natural immunity depends upon this fact of the non-development of these forces, although there may be a large growth of the invading germ. We can determine the fact of such development only by the reactive expression which may arise.

It would then seem necessary that we include in our nomenclature the term "specificity," or at least that of specific infection, since the expression of the reaction from the toxins absorbed indicates the presence of a germ colony somewhere in the animal body which has given rise to specific disease.

These two terms, expressing the toxic power and the specific power of the organism, do not suffice to convey all the knowledge which we have of the natural infections, for, as you say, "even with the most of these [organisms] the local infection is the more conspicuous," that is, that the primary colony is the most prominent because of the production of attractive symptoms; and you continue, "From the site of the local infection the invading bacteria may gain entrance into the blood-vessels or lymphatics." This condition you would call bacteræmia, rather than use the older term septicæmia. Are there not almost insuperable obstacles to this change? The literature of bacteriology contains sufficient evidence to convince one that the power to enter the "blood or lymphatics" is natural or inherent in the germ; that it is an entity capable of being lost and regained by it; that it is closely associated with the power to produce toxins, and that it belongs as much in the nomenclature of bacteriology as does the toxic power (as an expression of which it may be considered).

Septicæmia, blood sepsis, used in relation to a specific pathogen means much more than it formerly did; it is well defined and pregnant with information; it is taken out of the category of generalized terms and crystallized. "Bacteræmia" would mean practically the same thing, but "septicæmia" depends upon the inherent potential of an organism to produce septicæmia, the infection of the blood by the organism. Can we say as much for bacteræmia, the inherent power of an organism to produce—what—bacteria?

These potential forces of the organisms must influence us in the formation of terms to express our knowledge of their action.

Specificity, toxicity, and septicity are clean cut, give every information, and depend absolutely upon the inherent qualities of these germs. Bacteræmia depends only upon the chance presence of the organisms in the blood.

Elsewhere, I have endeavored to show the dependence upon these potentials of all the forms of cases which we encounter in the acute infectious diseases, the toxic types, the septic types, and the admixture of these two. How awkward it would be to say the "toxic types" and the "bacteric types" of these diseases!

Reverting to the gonococcus, we know that it is specific, and that frequently the constitutional reaction indicates the formation and absorption of a considerable amount of toxin; there are malaise, fever, etc., the primary colony remaining limited to the canal wherein it has chanced to be lodged. But this is at times accompanied, as stated in your editorial, by meningeal, joint, cardiac, or other complications due to the presence of the coccus itself in the circulation, a specific septicæmia with such local expressions.

Gonococcic bacteræmia does not convey the appropriate idea, that of the development in the coccus of an inherent property to thus invade the blood. Gonococcic sepsis is better, it explains the entire condition.

The term septicæmia has been defined by most lexicographers as of double meaning, the one expressing the idea of intoxication from the products of putrefaction, and the other that of the presence in the blood of the organism giving rise to the putrefaction. There should be no such definition, for bacteriology has demonstrated that the former is an intoxication comparable to that from alcohol or other intoxicant, while the latter meaning alone should be retained in relation to the expression of the power of the germ to produce blood infection followed by remote local symptoms.

I trust you will pardon the criticism, since it is made only with the desire that, if we must coin a new term, all points may receive consideration.

Eugene Wasdin,
Surgeon M. H. S.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-second Annual Meeting, Held in St. Paul, Minn., on June 4, 5, 6, and 7, 1901.

CHARLES A. L. REED, A.M., M.D., OF CINCINNATI, PRESIDENT.

(*By telegraph to the* MEDICAL RECORD.)

GENERAL SESSION.

First Day—Tuesday, June 4th.

THE meeting was held in the Metropolitan Opera House, and was opened at 10 A.M. with prayer by Bishop H. B. Whipple. The address of welcome was delivered by Hon. R. A. Smith, Mayor.

President's Address.—See page 881.

DR. J. R. PENNINGTON, of Illinois, presented with appropriate remarks a portrait of the father of the association, Dr. N. S. Davis. A committee was appointed to endeavor to secure portraits of all of the other ex-presidents.

Report of the Secretary.—This report showed the present membership of the association to be over ten thousand six hundred, an increase of between fifteen hundred and sixteen hundred over last year. This was a larger increment than in any previous year in the history of the association.

Report of the Executive Committee.—In this report attention was directed to the fact that three hundred and ninety-one papers appeared on the programme this year, as against four hundred and ninety-one last year. The provision requiring abstracts to be furnished had not been heeded, for out of the three hundred and ninety-one only one hundred and ninety-six abstracts had been presented. For this reason, it was voted that "Hereafter no titles of papers be printed in the programme unless the required abstract is furnished and printed in connection with the same."

Report of the Board of Trustees.—This showed the association to be in a very flourishing condition. Thus, on January 1, 1900, the cash assets were $28,000; on January 1, 1901, they were $31,864.07, and on June 1, 1901, $45,254.

Report of the Committee on Legislation.—DR. H. L. E. JOHNSON reported that this committee had aided in killing the antivivisection bill, and that this measure had met with such crushing defeat that it was not very probable that it would be brought up in future. Section 15, House of Representatives bill 13,423, providing for a change in the postal regulations, which would have cost the journal department of the association alone $30,000 a year in postage, was defeated. Among other good things accomplished by this committee was the appointment of a committee to secure unification of medical practice acts, and of another committee to aid in promoting better State medical organization. It was recommended that the work of the committee on legislation be continued, and that an annual conference be held at Washington, D. C.

Report of the Committee on Reorganization.—DR. J. N. MCCORMICK, of Tennessee, presented this report, which contained the following recommendations, regarding chiefly a business section, to be known as the "House of Delegates":

1. The delegate body shall hereafter be known as the "House of Delegates of the American Medical Association."

2. The House of Delegates shall consist of not more than one hundred and fifty members, and shall be created as follows: (*a*) One delegate for every five hundred members or fraction thereof of the State and Territorial societies recognized by the American Medical Association; (*b*) one delegate from each of the sections of the American Medical Association, to be elected as are officers of the section; (*c*) one representative each from the United States army, the United States navy, and the United States Marine-Hospital service.

3. Delegates representing the State societies shall serve for two years, one-half, or as near as may be, of such delegates to be elected the first year for one year only.

4. Whenever the number of delegates exceeds one hundred and fifty, there shall be such a reapportionment among the affiliated State societies as will bring the total membership of the House of Delegates below that number.

5. The House of Delegates—as the sections—shall hold its sessions daily, from 9 A.M. to 12 M. and from 2 P.M. to 5 P.M., or so much of such time as may be necessary, provided that it shall hold no session on the morning of the first day of the annual meeting, nor during the time of the general sessions.

6. The general sessions of the American Medical Association shall be composed of members and delegates who may be in attendance at the annual meeting, and the time of meeting shall be 11 A.M. on the first day of the annual meeting, 7:30 P.M. on the first three days of the annual meeting, and 12 noon (or such other hour as may be agreed upon) on the last day of the meeting, which session shall be for the installation of the officers for the ensuing year and other concluding exercises.

7. All the officers of the association shall be elected by the House of Delegates, but no member of the House of Delegates shall be eligible to any office whose incumbent is elected by that body.

8. No one shall be elected a member of the House of Delegates who has not been a permanent member of the American Medical Association for at least two years.

9. The election shall take place on the morning of the fourth day of each annual meeting.

10. No one shall be elected to any office who is not present at the annual meeting at which the election occurs.

11. The officers elected shall be installed at 12 o'clock on the last day of the annual meeting.

12. The membership of the association, in addition to the delegates, shall be composed of permanent members, honorary members, and associate members.

DR. E. ELIOT HARRIS, of New York, then introduced the following resolution, which was adopted:

Resolved, That the report of the committee on organization be referred to a joint committee composed of the general executive committee and the enlarged committee on organization, representing, as it does, all the States, and that the joint committee meet at the rooms of the general executive committee at the Hotel Ryan at 3 P.M. to give a hearing to any member who desires to be heard on the subject of the report. Also that this committee be directed to report to-morrow morning.

SECTION ON PRACTICE OF MEDICINE.

First Day—Tuesday, June 4th.

Address of the Chairman.—DR. J. M. ANDERS, of Philadelphia, pointed out a few lines on which organizational and professional progress must be conducted, believing that, if the American Medical Association was to be one of the great powers of the country, it was of great importance that the proposed reorganization scheme be promptly effected, and due efforts be made to establish and maintain proper respect and forbearance between the various sections, to the end that they might work in perfect harmony.

Appendicitis.—Dr. John B. Deaver, of Philadelphia, stated that the appendix was the most vulnerable of the abdominal organs, from several causes. It was a structure in the process of retrograde metamorphosis. It was deficient in blood, nerve, and lymphatic supply. It was long, and its calibre was small; hence its drainage was easily interfered with. It was subjected to traumatism by the movements of the psoas muscle upon which it lay. It was apparent that the appendix might easily become the target for the destructive micro-organisms, when from any cause these were incited into activity, and it was specially noteworthy that a hollow, glandular organ remained intact only so long as the production and evacuation of its secretions continued normally. When this function was deranged, there were serious results: first, retention, stagnation, and decomposition of the appendix contents; second, pressure, leading to impairment of the appendix wall; third and most important, bacteria, especially the colon bacilli, were so increased in number and virulence that they were able to penetrate the coats of the appendix and set up their irritant processes in varying degrees. Such he considered to be the brief pathogenesis of appendicitis. The following classification was suggested as convenient and well founded: Acute appendicitis: (1) catarrhal, (2) interstitial, (3) ulcerative, (4) gangrenous. Chronic appendicitis: (1) catarrhal, (2) interstitial, (3) obliterating. One could not always distinguish between different pathological varieties of appendicitis. Apparent inconsistencies were explained by the fact that most symptoms were due to peritoneal inflammation by extension. The majority of inflammations of the appendix were chronic in nature; many so-called acute cases represented exacerbations, the lighting up of a quiescent focus.

Nature's Effort at Cure.—He had never seen much good from efforts of nature to cure. The abscess itself, by its tendency to infect the peritoneum, was a grave menace, and even if the abscess ruptured into a hollow viscus the situation was not much better. Two points of the pathology were specially emphasized: First, the practical non-existence of any form of inflammation which by obliterating its lumen rendered the appendix harmless. Second, the appalling rapidity and suddenness with which the appendix might suffer bacterial invasion and necrotic degeneration with resulting general peritonitis. Upon these two facts treatment was founded, as well as the claim that appendicitis was a purely surgical affection. Few diseases presented their signs and symptoms in such varied form and locality as appendicitis. In all abdominal cases it was advisable first to exclude appendical irritation, because careful examination would often reveal, as due to it, affections otherwise apt to be classified as "entero-colitis," "acute dyspepsia," "cholera morbus," etc. In all inflammations of the appendix not entirely chronic, there were three cardinal symptoms: pain, tenderness, and rigidity. Pain was the most significant; so much so that he regarded with suspicion every clinical history containing such terms as bellyache, inflammation of the bowels, neuralgia of the stomach, etc. Pain in appendicitis had certain characteristics: above all, it was paroxysmal, cramplike, and colicky, and might at intervals almost disappear. It was usually first referred to the umbilical and epigastric regions, becoming localized in the right iliac fossa only after the lapse of several hours, but not in all cases. The medical attendant should first examine at a distance from the seat of disease, and slowly and gently approach the tender area. A localized spot of extreme tenderness he considered to be the surest indication of pus formation; conversely, abrupt cessation of such pain was apt to denote complete gangrenous change and a paralysis of peripheral nerve filaments by toxin absorption. He did not depend to any extent upon the blood examinations. A leucocytosis of over 20,000 usually indicated pus unless it be shut off by adhesions or the individual was overwhelmed by septic absorption. The symptoms of appendicitis were seldom proportionate to the appendical lesion; therefore, it should suffice to diagnose early the inflammatory involvement, which was of itself sufficient indication for treatment. The aseptic scalpel promptly used was the only treatment.

Dr. Delancy Rochester, of Buffalo, made a strong plea for the value of the blood count during the acute inflammatory stage, particularly during the development of pus. When there was an elevation of temperature there was a higher leucocytosis.

Dr. J. B. Kelley, of Philadelphia, did not think that any medical man should treat a case of appendicitis after the first twenty-four hours.

Dr. J. A. Witherspoon, of Nashville, Tenn., considered appendicitis both a medical and a surgical condition. Many of the patients got well, not by medical treatment, but by going to bed, stopping all nourishment, applying ice-bags, and keeping perfectly quiet.

Some Phases of Malaria.—Dr. J. B. McElroy, of Stovall, Miss., cited a case in detail, discussing some of its phases. As to perniciousness in malaria it was a well-known fact that in these infections the æstivo-autumnal parasites were found in exceedingly large numbers. There were usually two predominating broods of parasites in the blood of patients with pernicious fever; but Marchiafava and Bignami had reported cases in which the viscera as well as the peripheral circulation showed a very small number of parasites. We must look for the causes of malignancy elsewhere than in the large quantity of parasites. These causes might be found in what had been termed the biological characteristics of the æstivo-autumnal parasites. The first of these was their capacity for rapid propagation. Another characteristic was their disappearance from the peripheral circulation to complete their cycle of development in other vascular areas. The virulence of these parasites should also be taken into account. Many attempts had been made to demonstrate a malarial toxin, and there was good evidence that such a toxin existed, although it could not be demonstrated. It was probable that this property of the æstivo-autumnal parasites more than any other accounted for malignancy in malaria. Another proof of the great virulence of these parasites was the occurrence of hæmoglobinuria. The blood offered other evidence of malarial infection besides the presence of parasites, viz., pigmented leucocytes, and the characteristic leucocytic variation. In all the cases studied there were pigmented leucocytes. If pigmentation and leucocytic variation were evidences of malarial infection when parasites were few or absent in the peripheral circulation, hæmoglobinuria must be malaria, and being malaria was a most striking evidence of the extreme virulence of the æstivo-autumnal parasites. Phenomena occurring in these infections after the disappearance of the parasites, which had been termed post-malarial, also furnished evidence to support the toxin theory. As to immunity, it had not infrequently been stated that the negro was relatively immune from malarial infections, sometimes absolutely so. These statements were not in accord with the speaker's experience with the negro in the southern Mississippi valley. Forty-one per cent. of whites were infected with malaria. Five who did not have malaria were away from home during the greater part of the malarial season. So, excluding these, the percentage of malarial morbidity would be about fifty-three per cent. among the whites. The were one hundred and eighty-four blacks on one plantation, and of these sixty-one were infected. Concerning gangrene,

Professor Osler's classification of gangrene was given. Multiple spontaneous gangrene of the limbs in young and middle-aged subjects might occur without obvious cause. He reported a case of multiple gangrene in æstivo-autumnal infection, and referred to a second case of spontaneous gangrene associated with malaria.

SECTION ON SURGERY AND ANATOMY.

First Day—Tuesday, June 4th.

Chairman's Address.—Dr. A. J. Ochsner dealt chiefly with the etiology of diffuse peritonitis and appendicitis and their prevention. Death in almost every case resulted from diffuse peritonitis. This, in order of frequency, ensued as follows: 1st, gangrenous form; 2d, suppurative form; 3d, cases in which the cæcal end was closed and the distal end dilated; 4th, in rare cases of abscess of the appendicular wall; 5th, septic thrombosis. Turning to those factors which should guide us in our treatment of all cases of appendicitis, Dr. Ochsner pointed to the paramount importance of the omentum, which acted not alone by mechanically protecting the area, but by virtue of its great blood supply carried away the inflammatory products. Another factor of material aid in indicating our treatment was the absolute rest afforded by the tense abdominal muscle. Whatever course would yield to nature the greatest help in this direction was the right one to pursue. Upon these and similar observations made in the course of the last nine years he concluded that the rational management of all forms of appendicitis, particularly those which had been classified as too late for early operation and too early for late, was founded on the following simple and successful rules: 1st, absolutely no food should be given by the mouth; 2d, no cathartics should ever be used; 3d, frequent gastric lavage should be performed. Since the introduction of this treatment, the mortality of that great class of cases just cited had in his service decreased three-fourths. By it he felt emphatically that almost without exception every fulminating case could be converted into a simple chronic condition. Over ninety per cent. of these patients had recovered. Of the three factors, perhaps the most important was gastric lavage: it stopped nausea, meteorism, and pain which resulted from peristalsis. Of five hundred and sixty-five cases operated upon in the last four years, embracing every conceivable variety of the disease, the mortality was but three and one-half per cent.

Remarks on the Surgery of the Spinal Cord, with Illustrative Cases.—Dr. Andrew J. McCosh, of New York, said that one hundred years ago Sir Astley Cooper had urged the desirability of early operation even in cases apparently hopeless. To-day, with no less vigor and with greater hopes of success, we could urge exploration of the spinal canal with an astonishingly small percentage of risk. It was definitely known now that the results obtained from operative work on the cord did not promise such brilliant results as similar explorations on the brain. The difficulty of establishing a correct differential diagnosis between hæmatomyelia and certain other conditions was great. When such diagnosis could not possibly be established he advised immediate exploratory incision. Even when the symptoms seemed to point to complete severance of the cord, he felt that operation was not contraindicated, partly because of the fallibility of human judgment, partly because of the remote possibility of a physiological union of the completely divided cord. Tumors were more successfully dealt with here than in the brain. The mortality after operation should not exceed ten per cent. He reported six cases; two of the patients died of secondary sarcoma, two recovered, two died of septic decubitus. Unfortunately, every case of tumor of the cord was too frequently subjected to long anti-syphilitic treatment, and when finally operated upon, degenerative processes from pressure necrosis were often so advanced as to make the result hopeless. There were two types of operation. The first consisted in removal of the spines and laminæ, the second in an osteoplastic resection. This being difficult of execution, the speaker preferred the first. The skin incision, for trophic reasons, should be as high as the lesion would permit. Speed was of paramount importance, pressure the only possible hæmostatic. The after-treatment was simple, no support whatever being used.

Spina Bifida, with the Report of an Interesting Case.—Dr. Paul F. Eve, of Nashville, outlined in detail the etiology of this condition. Although the tumor was almost invariably pre-natal in development, numerous cases had occurred in which it was not manifest until after the third month. Since the affection was so invariably fatal one would be justified in assuming risks which under other conditions could not be admitted. Prior to the development of modern surgical technique good results were obtained in many cases by the injection of various astringents. Now, however, in most cases, and certainly in all those in which ample skin-flaps could be obtained, and in which the tumor was distinctly pedunculated, no one should hesitate to operate. The speaker thought the condition was analogous to hernia, and believed it should be treated accordingly. Among the contraindications to operation were: age of the child (less than three months old), paralysis, and hydrocephalus. The operation was specially indicated when the child was seven or eight years old, or when the tumor was of rapid growth.

Methodical Exploration of the Brain for Fluid.—Dr. C. Fenger, of Chicago, read this paper. He discussed subcortical purulent collections only. He disagreed with von Bergmann, who maintains that all cerebral explorations should be made with the knife, and at a depth of not more than 3 to 4 cm. The speaker preferred a long, blunt aspirating-needle used as follows: A half-inch trephine opening was made over the suspected area. When aspirations anteriorly, inferiorly, and posteriorly had proved negative, another trephine opening was made over the same hemisphere as far from the first as possible. If necessary this double operation should be repeated on the other side. With this instrument he invariably tapped the lateral ventricles and carried the needle without dread through three or four inches of cerebral matter. He thought this method was vastly superior to the limited one of von Bergmann.

Immediate and Remote Effects of Brain Injury.—Dr. D. S. Fairchild, of Clinton, Iowa, said that of paramount importance in the treatment of these cases was a knowledge of the way in which the injury had been received. There were three types of cases as regarded symptoms: (1) Indeterminate trauma, without symptoms; (2) the same with symptoms; (3) definite trauma with marked symptoms. Anatomically he would group these lesions as follows: (1) pressure lesions, giving Jacksonian epilepsy; (2) trophic lesions followed by minute sclerotic changes which ultimately often terminated in insanity. In concluding he said that injuries in which the brain matter as a whole was violently shaken, as by falls from a height, were infinitely graver in every respect than those in which a local lesion was produced by a concentrated force. Cerebral scar tissue, he said, frequently underwent cystoid degeneration.

Dr. W. W. Keen, of Philadelphia, opened the discussion. He agreed cordially with the previous speaker in his radical views regarding the treatment of spina

bifida. He regretted that Dr. Fenger had limited his paper to a discussion of the search for pus only. Ten years ago he had advocated free opening of the lateral ventricles, their irrigation and drainage. This procedure was in no way to be dreaded. Less than six weeks ago he had operated on a man whose skull had been fractured in 1892. Epilepsy appeared in 1899. On opening the skull over the lateral ventricle he discovered what appeared to be a cyst. No cortex intervened between the dura and the tumor. Upon opening the supposed cyst he found to his amazement and alarm that he had inadvertently entered the ventricle. The man recovered from the operation, but there was no cessation of his seizures. While many cases of cerebral hemorrhage presented typical symptoms, we must not forget, Dr. Keen said, that the period of intervening consciousness might on the one hand be abrogated, or, on the other, might extend into the sixth week.

Dr. McLean, of Detroit, seconded the assertion that spinal supports were unnecessary and that in spina bifida the treatment should be radical. Cerebral injuries differed very positively according to whether the patient had fallen or had been struck.

Dr. Frazier, of Philadelphia, described a new operation for the relief of trigeminal neuralgia. It consisted in a simple severance of the posterior roots of the ganglion. In dogs so operated upon physiological re-establishment of function had been found not to occur. The operation was to be recommended for its simplicity, for its freedom from hemorrhage, and because of the certain preservation of the cavernous sinus and the sixth nerve.

Dr. R. F. Weir, of New York, asked what was to be done in cases of cerebral injury not presenting classical symptoms. For many years he had done nothing. He now felt that the great Agnew was right when he insisted that in every case of this type an exploration should be made. He advocated the old operation on the Gasserian ganglion, believing that newer methods were incomplete and unnecessary. Particularly he emphasized the fact that after splitting the zygoma there was danger from non-union of this process, which might ultimately lead to a painful limitation in the power of the lower jaw.

Dr. Earle, of Milwaukee, said that Dr. Fairchild's radicalism, albeit advanced, was certainly not too pronounced to meet the crying needs of these somewhat neglected cerebral injuries. Every injury causing fracture of the skull must be capable of injuring the brain. The only safe attitude for the modern surgeon was to assume the presence of cerebral injury in every case and to act accordingly. He had found it in eighty-seven per cent. of his cases.

Dr. Moore, of Minneapolis, said that it was safe to operate for spina bifida in children under the age of three months, and that a sudden and complete evacuation of the sac was in no way dangerous.

Dr. R. H. M. Dawbarn, of New York, reported a case which he had operated upon in the presence of Landon Carter Gray, of New York. In this case there were the classical symptoms of right-sided epidural hemorrhage, but he found no blood. Death ensued in a week, and the autopsy revealed an immense clot on the paralyzed side. Dissection revealed that in this case the fibres had not decussated, an anomaly which the speaker thought was probably not so infrequent as had been supposed. There were, however, but two other cases on record, though this was very probably owing to unfortunate limitations placed upon the procuring of autopsies.

Dr. McCosh, in closing the discussion, emphasized the need of early operation and the fact that complete loss of reflexes did not necessarily contraindicate exploration.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

First Day—Tuesday, June 4th.

Chairman's Address.—The Chairman outlined the advances in gynæcology and obstetrics which had been made during the past year, and expressed the opinion that the field of spinal cocainization was very limited, not applicable in children, nor in major pelvic operations in women. There was no complete relaxation of muscular tissue while the patient was under its influence; therefore it was useless under most conditions and unreliable in obstetrics, because its application could not be accurately timed. He said that the only way at present to prevent uterine cancer was to remove all abraded surfaces in the cancer-bearing area in every woman. The present tendency was to remove the uterus, in cases of cancer, by the vagina. The literature of ovarian transplantation was reviewed, and the honor of having been the first to apply this principle was awarded to Dr. Robert T. Morris, of New York. According to the latest observations, ovarian tissue would grow and functionate anywhere in the pelvis when transplanted. Cæsarean section was now advocated in cases of placenta prævia, the result being the saving of two lives, for with present methods the child generally died. Statistics, he said, were accumulating to show that eclampsia was best treated by Cæsarean section. In this case also two lives would be saved, instead of one as hitherto. The shock of the operation was very insignificant. Enteroptosis was now treated surgically with excellent results. This was one of the most recent advances in gynæcology. The angiotribe had taken a prominent place in our armamentarium as a hæmostatic. Puerperal infection was now due solely to adventitious circumstances, and to the neglect of the midwife. There had formerly been too much neglect of obstetrics as a specialty, but in the future as much time would be given to this in the section as to gynæcology.

Post-Operative Hemorrhage.—Dr. Cordier said that the cause of most cases of post-operative hemorrhage was a slipping of the ligatures, the fault generally of the ligature material. The speaker's only fatality was due to his use of catgut, and he advised the use of silk in all intra-abdominal work. The use of the Trendelenburg posture in old persons was often productive of post-operative hemorrhage, because when the patient was restored to the horizontal position the blood pressure was increased and the surfaces that were anæmic before now bled. The speaker advised that a drainage tube be inserted for a few hours in every case when hemorrhage was to be feared. The symptoms of hemorrhage and shock were alike, and no one could differentiate the two conditions by the symptoms. If these symptoms came on a few hours after a slight operation, the cause was probably post-operative hemorrhage. The operator should then remove a stitch and insert a long hæmostatic forceps and see if there was any bleeding. If the symptoms were present when the patient left the table, the operator should put in a tube for a few hours and thus be safe. Shock almost always occurred during the operation and not after. One should give large decinormal salt infusions in these cases. If the injected solution was below 110° F., the patient would often have a chill.

Dr. McMurtry, of Louisville, said that the ligature material had nothing to do with the slipping of the ligature. An operator got the best results with the material and method with which he was best acquainted. If the broad ligaments were clamped before they were cut, and tied later, the tension was relieved and the ligature was not so apt to slip. A simple secondary operation was much more serious than the

most severe primary operation. Often in neurasthenic women the same symptoms appeared that were indicative of shock and hemorrhage, and it was difficult to differentiate them.

Dr. Gardner, of Maine, used catgut ligatures only, and then stitched with needle and running catgut suture all the parts ligatured.

Dr. Howard Kelly, of Baltimore, related a case of hemorrhage occurring eight days after operation, which was due to the catgut being absorbed. He used fine silk for ligatures, for if everything was sterile there was no trouble from silk afterward. Very often he applied two ligatures to the larger vessels. He made a careful inspection of the parts after operation and examined the woman as she was taken from the table. If in doubt, he opened first, caught all the large arterial trunks with clamps, and then cleaned out the blood.

Dr. H. O. Marcy, of Boston, advised the use of tendon as ligatures.

Dr. F. Holme Wiggin, of New York, used fine chromicized catgut for his ligatures. It should be taken direct from alcohol to the wound; he also used it as suture material. He had never had a ligature slip. He advised that with catgut a single knot be tied first and later a double knot, for such a knot did not slip. Most of the secondary operations that he had seen were the result of the use of silk as a ligature by other operators.

Dr. C. C. Frederick, of Buffalo, N. Y., had seen catgut slip but once in one thousand cases. Previous methods of sterilization were responsible for the too ready absorption. He employed formalin as a sterilizing agent.

Dr. Cordier in closing said he believed that silk ligatures *en masse* were perfectly safe, but that silk was contraindicated in pus cases.

Elimination of Peritoneal Infections and Prevention of Surgical Peritonitis.—Dr. G. G. Clark, of Philadelphia, read this paper. As a result of a study of seventeen hundred cases he was radically opposed to drainage after cœliotomy. Experiment proved that if granules of fuchsin were deposited in the pelvis, within eight minutes they appeared about the diaphragm, and in a few hours were to be found in the liver, lungs, and bone marrow. The micro-organisms were carried by the lymph up through the lungs and liver, and were there excreted. Drainage as ordinarily employed was resorted to too late, because by the time that the fluid would carry away the germs the damage was beyond repair. Therefore, it was advisable to get rid of as much pus as possible, and then in order to diffuse the rest throughout the peritoneal cavity one litre of decinormal saline solution should be left in the abdomen. This, however, was contraindicated in cases of ascites and of general surgical peritonitis.

Dr. Wiggin, of New York, stated that he published his results with this method in 1894, and had employed the procedure ever since. His present low mortality was due to this, for the method lessened the dangers of adhesions.

Dr. Howard Kelly, of Baltimore, said he never drained except in cases of general septic peritonitis, due to appendicitis. In cases in which septic foci were present he obtained sequestration by means of gauze.

Dr. Montgomery Baldy, of Philadelphia, did not favor leaving fluid in the abdomen.

Dr. Deaver, of Philadelphia, believed in drainage in pus cases.

The Accidents and Complications of Pelvic Surgery and their Treatment.—Dr. J. B. Deaver, of Philadephia, read a paper with this title. He said that post-operation adhesions were the bane of the surgeon, for it was impossible to get at them by way of the vagina. The region about the sigmoid flexure was the most dangerous place in the pelvis. When breaking up adhesions the omentum, when adherent, should be ligatured in small sections with fine silk and then cut. A cyst or innocent tumor which was adherent to and inseparable from the bladder or bowels should be removed as far as possible, and the remainder should be seared with the cautery. Rubber gloves should be used throughout the operation by all taking part in it. No minor gynæcology should be attempted when salpingitis or any other pelvic disease was present. Curettage was a dangerous operation if any infection was present. All women who had borne children had lacerated cervices, he said, yet not one in fifty thousand was operated upon. The strongest possible indication for repairing lacerations was a family history of cancer.

Dr. Merrill Ricketts, of Cincinnati, Ohio, said that in puerperal infection pus should be let out per vaginam, by puncture or incision.

Dr. Warner, of Columbus, Ohio, said that all lacerations should be repaired, for no one could know whether or not the patient would develop cancer. Cancer was hereditary in only one-third of the cases.

Dr. Steele, of Chicago, had saved many more patients by operating through the vagina first, and by the abdomen at a later period, than he had when using the abdominal route exclusively.

Dr. Watkins, of Chicago, had noted recurrences in only five per cent. of the cases in which pus had been evacuated from below.

The paper was further discussed by Drs. Henry, Smith, Harris, Carey, and Rosenthal.

GENERAL SESSION.

Second Day—Wednesday, June 5th.

The session was opened by an address by his excellency, S. R. Van Sant, governor of Minnesota.

Report of the Committee on Reorganization.—The general report of the committee on reorganization was then read by the secretary. Dr. E. Eliot Harris moved that the full report of the joint committee on reorganization, including the revised constitution, be adopted. This motion was carried by a large majority. Dr. J. N. McCormack then moved that the motion by which this report was adopted be reconsidered and that the reconsideration be laid upon the table. This was carried. It was then ordered that a copy of the revised constitution and by-laws be printed and mailed to each member as soon as possible. The committee on reorganization was then appointed an engrossing committee on the new constitution and by-laws.

Address on Surgery.—This was delivered by Dr. J. A. Wyeth, of New York (see page 892).

Report of the Prize Committee.—The committee on the American Medical Association medal reported that two essays had been submitted to the committee, but neither was deemed worthy of the prize.

SECTION ON PRACTICE OF MEDICINE.

Second Day—Wednesday, June 5th.

The Chemical and Microscopical Examination of the Blood.—Dr. W. Kelly, of St. Paul, read this paper. The blood serum, containing serum albumin and serum globulin, he said, was subject to chemical change in puerperal septicæmia, but in febrile disease serum globulin was less subject to change than was serum albumin. The pathological variation in the quantity of the phosphate of the serum was but slight,

and in that of the chlorides was not very great. A high percentage of chlorides was usual in anæmia. The larger the proportion of plasma the greater was the percentage of chlorides in the blood. Sodium salts were found chiefly in the plasma, being usually increased in watery blood. The amount of potassium found in the red cells was diminished in hydræmic conditions. Seegen, Chauveau, Cavazanni, and others had found, in normal blood, traces of glucose, which substance was increased by a diet of carbohydrates, and diminished by muscular exertion. The diastase ferment of the blood was found in the red cell and serum; it was said by Precka and others to have the power of coagulating the blood; this power was inhibited by the nuclein and increased by sodium sulphate and chloride. The presence of fat had been demonstrated in the blood after a hearty meal, and free fat both in health and disease had been frequently observed. Acetone had been found in fevers, and fatty acids in the blood of leukæmia, acute atrophy of the liver, and infectious diseases. The poisonous symptoms developed in cholæmia had been referred by most authorities to the presence of biliary acids. Isotonic tension and increased resistance of the red cells were peculiar characteristics of the blood in jaundice. Bile acids affected the union of hæmoglobin with the stroma of the red cells, rendering the hæmoglobin more readily soluble; this accounted for the solution of the red cells in jaundice, as well as in other conditions. The specific gravity of the blood might be increased by sweating, lack of food, and muscular exertion, and decreased by free imbibition of fluids. Homberger found that albumins, phosphates, and chlorides behaved differently in changing osmotic conditions. When a little acid was added to blood, albumin and phosphates passed from the red cells to the serum, while chlorides passed from the serum to the cells. But when an alkali was added, a reverse transfer was induced. In order to make a satisfactory examination of the blood, the apparatus must be absolutely clean, and the various stages of the process must be performed rapidly. The work must of course be done accurately.

The Leucocyte Count in Hemorrhage. — Dr. George Douglas Head, of Minneapolis, placed on record some experimental work regarding the leucocytes in hemorrhage, which gave results somewhat different from the one generally accepted. The same law, he said, seemed to govern the increase or decrease of leucocytes in the circulation of the dog as in man. There was in the dog a leucocytosis of digestion and also one following septic infections, just as in man. In dogs diminution in the number of white cells in the circulating blood immediately followed profound hemorrhage. This initial leucopenia was followed sooner or later by an increase in the number of leucocytes in the circulating blood. This was the so-called post-hemorrhagic leucocytosis of all writers. This leucocytosis of hemorrhage continued for at least seven days, sometimes much longer. In human beings immediately following hemorrhage there was an increase in the number of leucocytes in the circulating blood which had hitherto been overlooked because of the failure to make counts early enough after hemorrhage had occurred.

Pernicious Anæmia.—Dr. Thomas McCrae, of Baltimore, reported a series of forty cases, thirty-two in males and eight in females, in the service of Dr. Osler at the Johns Hopkins Hospital. During about ten years there the total number of medical patients was twelve thousand five hundred. Two of the patients with pernicious anæmia were colored. The ages varied from ten to seventy years. Worry and mental strain were factors in three cases. Oral sepsis was not invariably present in the recent cases. The most frequent symptoms were weakness, change of color, and loss of weight. The last-named was present in more than one-half of the cases, and emaciation was marked in ten. Pigmentation of the skin was found in eight and petechiæ in four instances. The liver was palpable in two cases and the spleen in six, but in none was the enlargement at all marked. When the cases first came under observation the hæmoglobin averaged 30 per cent.; the red corpuscles numbered 1,560,000 and the leucocytes 6,929 per cubic millimetre. Of the sixteen patients in whom the count was below one million, only four recovered. The average differential count for eighty-six cases was: polymorphonuclears 61 per cent., small mononuclears 31 per cent., large mononuclears and transitionals 4 per cent., eosinophiles 2 per cent., and a fraction of 1 per cent. of myelocytes. The average number of nucleated red cells per 1,000 leucocytes was 37, of which 23 were normoblasts, 5 were megaloblasts, and 9 were intermediary forms. In a comparison of the fatal and non-fatal cases, the average percentage of small normoblasts was rather higher in the cases that ended in recovery, but the number of megaloblasts was eleven times greater in the fatal cases. The nervous manifestations in fourteen cases varied from slight sensory disturbances to complete paraplegia, the prevailing type being spastic, with some inco-ordination and marked sensory disturbances. In some, the nervous symptoms seemed to vary with the state of the blood. The distinction from gastric cancer might be difficult. In this the higher count of the red cells, the lower color index, the lower percentage of small mononuclear cells, and the absence of megaloblasts were all important factors. Cases showing some features of splenic anæmia were hard to place. The average duration of life in seventeen fatal cases was twelve months. In eight, the course was under six months. One patient recovered, one was in good condition six years after the onset. The treatment included rest, fresh air, good food, and the administration of arsenic.

Dr. W. T. Higgins, of Cortland, N. Y., thought some doubted Hunter's theory and the importance of mouth conditions in the etiology of pernicious anæmia. Hunter's success in the treatment of this disease seemed to favor his theory. The speaker had treated one very marked case on the lines laid down by Hunter, with complete success. One should secure asepsis not only of the mouth and teeth, but of the nose and upper air passages.

Dr. W. D. Kelly, of St. Paul, referred to the importance of keeping the air from the veins in rabbit experiments; if air gained entrance, death would ensue in a few seconds.

Dr. McCrae, in closing, said that he agreed with Hunter in his theory, but he also believed that it was important to pay attention to the intestinal tract. Brilliant results had been obtained from the use of arsenic. One patient treated in 1880 was alive today. Another returned six years after cure of the anæmia with cancer of the stomach. One case was under observation for six years. Recovery might follow rest, fresh air, good food, epsom salts, arsenic, and oral asepsis.

Osmotic Pressure and its Relation to Uræmic Manifestations.—Dr. Heinrich Stern, of New York, thought physicians were laboring in the wrong direction when they referred the origin of uræmia and kindred affections to purely physiologico-chemical conditions. Most of the effete products were but little toxic *per se*. Potassium it seemed exerted the greatest poisonous qualities. Intravenous injection of urine for experimental purposes had shown what was not known before, namely, that uræmia was a consequence of the retention, not of one, but of all substances which normally enter into the composition of urine. There was no other substance in the blood of uræmia than in

that of health, the only difference being in the quantity. Uræmia, therefore, was a physical rather than a chemical anomaly.

Osmotic Pressure in the Body Fluids.—The cells of the body were more or less permeable to water. If for a certain period neither water nor salts were introduced or eliminated, all the watery constituents of the organism would become one homogenous liquid, and the same osmotic pressure would prevail over the entire system. There was no vital process in which diffusion, or osmosis, did not participate. The conditions for the evolvement of osmotic pressure always existed in the organism, for whenever two solutions came in contact by means of a semi-permeable wall, osmotic tension was displayed. When the excretory activity of the kidney was materially interfered with, the products of catabolism were retained in the blood. The great number of molecules dissolved in the plasma caused a high osmotic tension toward the less concentrated body liquids, but ultimately all the fluids of the body exhibited a similar degree of concentration. This process was accompanied by a series of manifestations, co-ordinate and successive, grouped together under the name "uræmia." This was really a mechanical intoxication, not a chemical one, being due to an abnormal increase in the osmotic tension of the blood plasma and the fluids of the body. The phenomena occurring in the blood after the injection of large amounts of concentrated salt solution were the same as those in uræmia; they appeared with the increase in the concentration of the blood, when elimination of the accumulated substances from the blood ceased. Noss had noticed tonic and clonic convulsions in dogs after the intravenous injection of a ten-per-cent. sodium-chloride solution.

Circulatory Disturbances Accompanying Cirrhoses with Inosculation of the Portal Branches with the Systemic Veins.—Dr. Charles G. Stockton, of Buffalo, N. Y., read this paper, of which the following were the conclusions: 1. Normal blood pressure in the portal vein was low, but when raised suddenly it was apt to be followed by symptoms of toxæmia, and these symptoms might be primarily relieved by purgation. 2. When the vascular changes and the raised portal blood pressure, that permit the passage of the portal blood into the systemic veins, were brought about gradually, the subject was better able to resist toxæmia, becoming, as it were, immunized to the offending portal blood; hence the symptoms were less striking, and with proper care as to diet and the exhibition of laxatives might be practically overcome.

Cirrhoses of the Liver due to Metallic Poisons.—Dr. Victor C. Vaughan, of Ann Arbor, Mich., said that lead and copper were the metallic poisons exerting the most pronounced effects upon the liver, and especially upon the connective tissue of the liver. Alcohol was one of the most important factors in the production of the cirrhosis of Laennec. Metallic poisons generally, if not always, produced changes in the liver cells which were characterized by a fatty degeneration or fatty deposits in these cells. The changes in the liver cells were prior to changes in the connective tissues—at least they were recognizable earlier. If hours or days after the administration of metallic poisons in not immediately fatal doses fatty deposits might be found in the hepatic cells, it was not presumable that the changes in connective tissue took place so rapidly. It was not often that the early stages of liver changes were seen at autopsy, therefore one had to rely on animal experimentation to trace the relationship of these changes. In a number of cases there occurred subsequently an overgrowth in the connective tissue in the liver. The effects of the soluble salts of aluminum hypodermically or intravenously administered to animals were seen first in the hepatic cells and subsequently in the connective tissue.

Treatment of Cirrhoses of the Liver.—Dr. John H. Musser, of Philadelphia, divided cirrhoses of the liver into those in which no symptoms occurred during life, and those that were not suspected until such an accident as hemorrhage made them apparent, *i.e.*, latent cirrhoses of the liver; and again into cases with the symptoms of portal obstruction, and those with evidences of biliary obstruction. Treatment was largely dietetic and hygienic, great care being taken to keep the functions of the gastro-intestinal tract in action, and the renal and skin secretions properly regulated. Caution was necessary in regard to the treatment of hemorrhoids in cases of cirrhosis. Many patients were operated upon without careful investigation, and the speaker had seen two or three deaths follow the operative treatment of hemorrhoids in cirrhosis patients. In cases of hemorrhoids a thorough knowledge of the state of the liver should be had before any operation was undertaken.

Ascites.—The management of ascites occurring in cirrhosis was interesting because of the late attempts at treatment through surgical intervention. In the treatment of ascites medicinal and surgical measures were applicable. The speaker relied upon a pill of digitalis, squills, and calomel, balsam of copaiba, and early and frequent tapping. One should not be appalled at the frequency of tapping required. In one case the abdomen had been tapped one hundred and ninety times. Among the cases operated upon in Philadelphia by opening the abdomen, a very large percentage had been relieved or cured.

Cirrhoses with Pigmentation.—Dr. Thomas D. Futcher, of Baltimore, read this paper. Pigmentation of the skin and tissues was associated with hypertrophic cirrhosis of the liver rather than with the atrophic form. Pigmentation was associated with the hypertrophic cirrhosis of the liver which occurred in the disease described by von Recklinghausen as "hæmochromatosis." Diabetic cirrhosis with bronzing of the skin was probably identical with von Recklinghausen's hæmochromatosis. So far as the speaker knew, only four cases of cirrhosis of the liver with general pigmentation (hæmochromatosis) had been reported in this country.

Rheumatic Stimulants.—Dr. James J. Walsh, of New York, said that rheumatism, gout, and catarrh were similar. Acute rheumatic arthritis was an acute infectious disease of microbic origin. Its similarity to gonorrhœal rheumatism pointed strongly to a microbic origin. Joint symptoms occurred in certain toxæmias, but there might be serious involvement of joint structures without necessarily any microbic metastasis. Painful affections around a joint afforded evidence of the fact that the nervous mechanism supplying the joints was extremely sensitive to disturbances of circulation, and also that the tissues in the neighborhood of joints were liable to chronic inflammation. Among forty cases, fifteen had so-called rheumatic symptoms due to flat foot. The nerves were much more sensitive in damp weather.

Occupation Neuroses.—Any occupation involving frequent repetition of muscular movements might produce a neurosis, even so simple an action as sweeping, if done as a regular occupation, often resulting in such a condition. Brachyalgia from frequent and badly directed use of the small muscles of the forearm was well known in telegraphers, writers, typewriters, piano players, etc. As a result of a sort of sympathy with the lower arm the upper arm and shoulder often suffered from a decided ache, and it was surprising, the author said, how often this ache was treated as rheumatism. In many other occupation neuroses, antirheumatic treatment had been instituted.

Acromegaly Presenting Features of Unusual Interest.—Dr. Charles Lyman Greene, of St. Paul, Minn., presented the case of a man twenty-five years old who for some years prior to the development of this disease had spent the winter on the ice. Exposure to cold and dampness had been mentioned by writers as a predisposing or exciting cause. Five years ago a rapid enlargement of the hands and feet occurred with change in the physiognomy. The enlargement of the hands and feet steadily progressed. Three years ago swelling of the knee-joint, lassitude, and general weakness appeared. The patient complained of languor and weakness, but had had none of the severer pains in the lumbar region or limbs. There was no disturbance of the special senses or of the nervous system. Enlargement of the upper jaw had accompanied that of the lower jaw, depriving the case of one of the so-called typical signs of the disease. The tongue was large, and the larynx and its cartilages also appeared to be the seat of hypertrophy. The radiograph demonstrated the remarkable enlargement both in length and thickness of the bones. A feature of especial importance was the marked increase in the bulk of the overlying tissues, which presented the appearance and sensation of hard œdema exactly resembling myxœdema. The treatment had been solely by thyroid extract, the result being an immediate and marked amelioration of the disease.

The Election of Officers resulted as follows: *Chairman*, Dr. Frank A. Jones, of Memphis, Tenn.; *Secretary*, Dr. Robert B. Preble, of Chicago.

SECTION ON SURGERY AND ANATOMY.

Second Day—Wednesday, June 5th.

The Mortality of Appendicitis.—Dr. J. B. Deaver, of Philadelphia, based his remarks on statistics of appendicitis occurring during the year 1900 at the German Hospital. Of the total number operated upon, 268, 144 were acute and 124 chronic. The mortality in the acute cases uncomplicated by intercurrent disease was 15.9 per cent. In every case the appendix was ablated. The time elapsing from the onset of the symptoms to operation varied from a few hours to fifty days. Among the chronic cases there was but one death, this being due to rupture of an ovarian cyst. Autopsy was made in every case of death occurring in the hospital. The speaker divided his fatal cases into three classes according to when death occurred: (1) prior to operation, (2) during operation, or (3) following operation. Septic peritonitis was a general cause of death. It arose in various ways. Certain cases, the fulminating, were invariably lethal despite all operative promptness. These cases were characterized by absence of fever, slightly elevated pulse, absence of leucocytosis, and almost invariably by severe disturbances attendant during anæsthesia. Second in importance to removal of the appendix was thorough search for hidden pus cavities. By early operation and exsection we should successfully avoid (1) fæcal fistulæ, (2) subsequent attacks, (3) necrosis of the bowels. Of eleven patients not operated upon, three died, and six left the hospital with a swelling in the right side of the abdomen. Every death occurring in the second attack could have been prevented. Upon whom, Dr. Deaver asked, should this responsibility rest?

Some Unusual Features of Appendicitis, and Their Treatment.—Dr. Ernest Laplace, of Philadelphia, said that in the numerous affections grouped under the title appendicitis were a great many varying pathological conditions and symptoms. In every fatal case there had existed a time which was not "taken at the flood." Of all symptoms, the induration of the muscles on the right side was perhaps of greatest value. Pain was frequently referred to the opposite side, and was hence of secondary importance. Appendicitis as such did not kill; the fatal condition was diffuse peritonitis. Leading to this were three stages: (1) Inflammation limited to the appendix; (2) circumscribed abscess; (3) septicæmia. The speaker advised continuous irrigation, the operator being careful, however, to avoid hydrostatic pressure.

The Knot within the Lumen in Intestinal Surgery.—Dr. F. G. Connell, of Chicago, read this paper. The position of the knot was a point of particular import. It should not lie upon the serosa, and hence, since it cannot be extraperitoneal, it must lie upon the mucosa. It seemed strange that the operators of to-day who have devoted so much attention to a study of the submucosa should have overlooked the writings in 1843 of Gross, then of Louisville, who recognized not only the existence of this layer, but also its surgical importance. The actual thickness of the submucosa is one two-hundred-and-fortieth of an inch, that of a needle is one-fortieth of an inch. With this disparity it would seem scarcely possible that any operator could split this layer. Dr. Connell's method was one by which all knots must lie within the lumen of the gut, and in some respects it resembled Maunsell's. The results in nineteen cases in which it had been used seemed to indicate that of all stitches it obviated best the liability to leakage, was most rapid, provoked fewer adhesions, while it did not yield.

Dr. Steele, of Chicago, was impressed with the value and accuracy of Dr. Deaver's paper, and he thought that every hospital in the land should insist upon an autopsy in every fatal case. He indorsed the advocacy of continuous irrigation, feeling that since it gave such good results in joints, it should be of equal value in abdominal surgery.

Dr. J. B. Murphy, of Chicago, agreed cordially with Deaver in every detail, but asked the following questions: "What constitutes suppurative peritonitis? Does the term signify simply a collection of cream-colored pus, or is its more important characteristic a destruction of the endothelial cells of the serosa? Is relief of abdominal tension of as great import here as elsewhere? Can a diagnosis of inter-peritoneal lesions be made from a study of the symptoms?"

Dr. Knight, of Connecticut, cited two cases to illustrate the importance of leucocytosis in appendicitis. Thorough washing of the abdominal cavity, he said, was better than continuous irrigation.

Dr. Andrews, of Chicago, asked whether or not the abdominal cavity should be drained or washed out. He said that probably all cases of so-called general peritonitis in which recovery took place were localized; all others ended fatally. Relief of tension was as important in abdominal work as elsewhere. Fowler's recommendation, that the patient should be tied down in the bed, if necessary to secure perfect rest, was a very valuable one. Connell's stitch, he said, was far superior to any other stitch extant. Its two great merits were that it was continuous, and that it acted as a clamp.

Dr. Harris, of Chicago, said it was not possible as yet for any one to diagnose intra-abdominal conditions, hence the only safe course was early operation.

Dr. Moore, of Minneapolis, said that Dr. Deaver's doctrine was pernicious and dangerous. We must have the extremists to show the mid-paths, but except in great metropolitan hospitals such radicalism was criminal and such teaching fatal.

Dr. R. T. Morris, of New York, said that principles must be taught to medical students as they are taught to students of law. If these principles enjoined early operation, early operation should be taught. Leucocytosis was of collateral rather than

determining interest. In the treatment of appendicitis one should endeavor to establish an alliance with the phagocytes. The patient should be left alone, and the surgeon should neither irrigate nor pack. Blood washing, to insure removal of the toxins, was of greater importance than abdominal lavage.

Dr. Deaver, in closing, said that when the peritoneum was red and abraded, the case was beyond the aid of mortal man. Relief of tension was of paramount importance. There were symptoms which pointed to definite intraperitoneal conditions. When the belly walls were hard and the onset was sudden, without fever or increased pulse, and there was bad reaction to the anæsthetic, the case was grave. Leucocytosis might indicate, but never contraindicated operation. Fowler's position was good. Surgical teachers should have the courage of their convictions. Early operation was without the slightest doubt the *sine qua non* in the treatment of appendicitis.

Anatomical Technique.—Dr. Jackson, of the University of Missouri, detailed the technique of cutting sections and the methods of studying them in use in his laboratory. A fifty-per-cent. solution of formalin was injected and followed within an hour by the usual pigments. The body could then be cut with an ordinary butcher's saw and knife into sections which possessed india-rubber-like strength, and which when carefully studied and drawn created in the student's mind a picture which enabled him "to see directly through his patient the relation of every organ to its neighbor and to the surface."

The Nature of the Cancerous Process.—Dr. Roswell Park, of Buffalo, said that the question of the etiology of cancer was one of the oldest problems in the history of medicine. It had been approached from (1) the diathetic, (2) the embryological (Cohnheim), and (3) the parasitic side. For the first little could be said. The second represented a great advance, in that it explained the cause of the teratological type of tumors; it did not, however, explain the development of the typical neoplasm. Granting the ubiquitousness of the parasite, one could easily explain, in a measure at least, the relation of trauma to cancer. For a proper investigation of the etiological factors in this research there were needed the combined investigations of the chemist, the clinician, the pathologist, and the histologist. The speaker's more weighty arguments in favor of parasitism were: 1. Analogy. In trees and plants tumors were frequent; they were often known as tree cancers; these were parasitic. 2. Comparative Pathology. Tumors are common among the invertebrates, almost all being produced by protozoa. 3. Granulomata. We knew the causes of these growths; they were often as fatal as cancer, and they yielded to the same treatment. 4. Metastases. 5. Auto-infection. Cancer bodies must be either cell degenerations or parasites. They could be reproduced only from a cancerous process. This, the speaker held, was no bacteriological problem. There was reason to suppose that these new organisms belonged to a type of life hitherto unknown. Koch's laws might or might not be valid in regard to them. That the duration of cancer was long was no argument against the parasitic theory, for two well-known microbic diseases, syphilis and leprosy, took longer to kill than did cancer. Dr. Park expressed the hope that a drug might be found which, acting like quinine in malaria, would give the physician a similar control over this new protozoan.

The Present Status of the Carcinoma Question.—Dr. N. Senn, of Chicago, said that the etiology of cancer was the most important question of the day. Carcinoma resulted from an atypical proliferation of epithelial cells, and as carcinoma originated in epithelial cells, it could not exist in mesoblastic tissues. Extension of a tumor to adjacent tissues afforded proof positive of malignancy. The present alleged increase of carcinoma was more imaginary than real, he said. Heredity was in his belief a potent factor in the causation of the disease. When cancer occurred in persons under twenty-three years of age, it was very malignant. The growth seldom followed a single injury, but one which was often repeated. Inoculation had failed to support the parasitic theory. Direct injection into a carcinoma did not stay its development. The future treatment of cancer, Dr. Senn believed, would consist in the injection of materials which should change the embryonic cells into harmless adult epithelium.

Early Diagnosis of Carcinoma.—Dr. G. A. Powers, of Denver, said that in not more than nine per cent. of carcinomatous cases did the patient apply to the surgeon early enough. The laity must be educated in this matter just as it has been in regard to tuberculosis. The examination of the blood and of the gastric juice was of little value in detecting hidden carcinoma. Sera might evidently have a use similar to that of tuberculin. It was questionable whether a preliminary microscopic section should be made for diagnostic purposes, for many felt that this procedure might spread the growth. He did not share this opinion, however, believing that every case should be subjected to the pathologist.

The Pathology of Breast Carcinoma and its Relation to Early Diagnosis and Treatment.—Drs. W. S. Halsted and J. C. Bloodgood, of Baltimore, presented this communication. They held that the problem was difficult because of the great variety in the nature of breast tumors. There was no doubt, however, that every breast tumor seen by the surgeon should be excised. The authors' deductions were based on a study of four hundred and twenty-six cases from the Johns Hopkins Hospital. Of all surgical cases entering this hospital, 2.4 per cent. were carcinoma, and of these 39 per cent. were inoperable.

Carcinoma of the Cæcum.—Dr. W. J. Mayo, of Rochester, Minn., said that iliocæcal carcinoma was not infrequent, seven per cent. of all neoplasms of the bowel involving the cæcum. The affection might occur at any age; its tendency was always to form a ring-like constriction. The duration was often long, even up to twelve years. The differential diagnosis from tuberculosis was difficult. Impaction of fæces and dermoids were conditions which complicated the diagnosis.

Improved Method of Resecting High Rectal Carcinomata.—Dr. R. F. Weir, of New York, read this paper. All were familiar, he said, with the dangers of Kraske's operation, and it was especially difficult of execution in the case of high-lying growths. Maunsell had suggested the pulling down of the tumor through the anus—a sort of artificial intussusception. It was, however, found that even though the anus was dilated or incised, the procedure was difficult and dangerous. It had, however, suggested to Weir the following technique: "Open the abdomen in the median line, separate the bladder and fret the gut to the lower rectal segment from its peritoneal attachment. Cut the gut below the growth and carry the tumor through the abdominal wound. Have an assistant pass a narrow-bladed forceps through the dilated anus to grasp the severed end of the upper bowel and the margin of the lower segment. These without effort are pulled well beyond the anus, sutured, and readily returned to place. A drainage tube is inserted in the peritoneal space; the abdominal wound is then closed."

Treatment of Malignant Diseases by Surgical Operation.—Dr. F. S. Dennis, of New York, said that certain life-insurance statistics, not yet published, showed an appalling increase of cancer in the past thirty years. In some localities, notably those from

which the younger portion of the population had migrated, the increase reached nearly two hundred per cent. Of all the modes of treatment, none was comparable to free excision. Of the many drugs which had been tried, thyroid extract would kill the odor and relieve the pain, but would not cure. In conclusion, he said there was no mortality after operation in the early stages of cancer. Recurrence after three years should be regarded as a new infection. Favorable cases gave eighty-three per cent. of cures.

Method of Operating on Carcinoma of the Tongue.—In the absence of Dr. J. C. Warren, of Boston, Dr. C. Fenger, of Chicago, detailed his method of procedure. As yet the percentage of cures did not exceed ten, and in cases of growth at the base of the tongue it was very much less. The lymphatic drainage of the tongue should be a guide in determining the extent of this operation, and until the importance of this was recognized, the author held there would be no improvement in these statistics. The glands on both sides of the neck must be removed. Death ensued in less than two years in all cases not operated upon. Aphonia was caused more by the contraction of the scar than by the loss of the larynx. The taking of a double pedunculated skin flap from the neck was the best mode of preventing this contraction.

Dr. Rodman, of Philadelphia, said that the belief was gaining ground that carcinoma was parasitic. Until recently the disease had not been found among negroes and Indians, but why should this have been the case unless the growth was due to germs?

Dr. Dawbarn, of New York, indorsed Bloodgood's view that all breast tumors should be extirpated on sight. In operating on carcinoma of the tongue the chief cause of death was shock induced by hemorrhage. The speaker could not agree with Fenger, who doubted the desirability of ligating the carotids. He advised the rubbing of all wounds which would later be bathed in pus with aristol, which formed an insoluble albuminate as capable of protecting from absorption as is granulation tissue. He did not pack the buccal cavity, but irrigated every two hours. The position of the patient was important; the head should be kept low for weeks. Deglutition was materially helped by grafting the twelfth nerve into the stump of the tongue.

Dr. Leavings, of Milwaukee, said the embryology of the teeth afforded a strong argument against Cohnheim's theory, as here more than at any other spot in the body were collected useless masses of embryonal cells.

Dr. McKenzie, of Oregon, believed in the parasitic origin of carcinoma. His belief was founded on clinical study. It was the exposed portions of the body, those areas particularly liable to trauma, and hence open to infection, which were found by the clinician to be almost without exception the site of carcinoma. The new growth seemed always to have been preceded by some anatomical disorder of the part.

Election of Officers.—Dr. Deforest Willard, of Philadelphia, was elected *Chairman*, and Dr. J. B. Bullitt, of Louisville, *Secretary*.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Second Day, Wednesday, June 5th.

Atresia Hymenalis.—Dr. O. Thienhaus, of Milwaukee, Wis., read this paper. The occurrence of hæmatosalpinx, he said, proved that the atresia was of inflammatory origin. Gonorrhœa of the new-born often affected the vagina, and was a very common cause of atresia. If hæmatosalpinx was present, it must be removed by abdominal section. Simple vaginal incision was fatal in seventy per cent. of cases.

The paper was discussed by Drs. A. H. McDermott and A. Goldspohn, of Chicago.

Results, Immediate and Remote, of Conservative Surgery.—Dr. A. Goldspohn, of Chicago, presented this communication. In ninety-seven cases of cystic degeneration of the ovary treated conservatively by excision and ignipuncture, there were ten pregnancies. In all of those cases in which the operation was performed through the abdomen the results were satisfactory two years after the operation. In one-half of the cases treated by vaginal incision the results were unsatisfactory. In cases in which an inguinal incision was made, the results were satisfactory. The appendages were more easily secured in this way. In eighty-seven per cent. of the operations done for retroversion by the author's inguinal method perfect results were obtained.

Dr. J. W. Bovée, of Washington, D. C., believed that if it was necessary to remove a part of a tube it was better to remove it entirely; and when there were extensive incisions, the ovary should be removed entire. When they were treated by ignipuncture, they were covered by adhesions, and pain and discomfort generally remained. The stormy menstruation of such cases was worse than the artificial menopause.

Dr. B. Cohn, of Buffalo, stated that he had examined one hundred patients operated on in the manner described, and in more than half a secondary operation was necessary. In thirty-five per cent. of the cases pus was found. The part of the ovary left after such operations was generally found to have undergone degeneration.

Electrothermic Hæmostasis in Abdominal and Pelvic Surgery.—Dr. A. J. Downes, of Philadelphia, said that electrohæmostasis was the ideal method in abdominal surgery, especially in appendectomy. The instruments used consisted of the author's angiotribe and hæmostatic forceps, provided with a platinum strip in the jaws and connected with a storage battery. The operation left a homogeneous mass in which no vessel nor nerve could be detected.

How to Deal with Uterine Myomata.—Dr. E. E. Montgomery, of Philadelphia, said that thyroid extract exerted a special influence on uterine epithelium. It arrested bleeding and relieved pain. Both in normal and carcinomatous uteri large doses must be employed, but the remedy was of value only in the milder cases. Treatment by electricity was condemned. Fibroids should be removed by enucleation, a vertical incision being made and as many growths as possible being removed through one incision. If there was much mutilation, the operator should drain on account of the danger of hemorrhage, but it was very rare that the uterus must be sacrificed. Submucous fibroids should be removed by the vagina after dilatation and splitting of the cervix.

Dr. S. C. Gordon, of Maine, said that hysterectomy should be done for the removal of all fibroids that caused any symptoms.

Dr. G. B. Massey, of Philadelphia, stated that it required at least six months of treatment by electricity to influence favorably any fibroid.

The question was discussed further by Drs. G. H. Wathen, of Louisville, and V. A. P. Dudley, of New York.

Cancer of the Cervix Uteri.—Dr. J. M. Baldy, of Philadelphia, said that cancer of the cervix was practically incurable, even with the advances that surgery had made up to the present day. According to reliable statistics, a cure resulted in less than five per cent. There was considerable difference of opinion between expert pathologists as to the appearance of early cancer examined under the microscope. A critical analysis of the Johns Hopkins Hospital reports would show very unfavorable results. Too much stress

in the past had been laid upon the microscopic findings, and too little upon the clinical symptoms. Hemorrhage and progressive loss of flesh and strength were the earliest symptoms. Any single show of blood occurring one year after the menopause without trauma was, in his experience, almost invariably due to cancer. It might be only a few drops of blood after coition, or a constipated movement of the bowels. It was extremely rare to have blood from any other cause.

Dr. J. G. Clark, of Philadelphia, strongly advocated the use of the microscope because by it a diagnosis of cancer could be made in many cases.

Dr. F. H. Wiggin, of New York, said that any increase in flow in a woman over thirty years of age was suspicious. If a case was seen before six months had elapsed from the inception of the disease there was a fair chance of recovery. If the report of the pathologist was doubtful and the clinical symptoms were marked, the surgeon should operate first and examine later.

Dr. E. Ries, of Chicago, described his method of extirpation of uterus and appendages together with all glands in the pelvis. He claimed that he had good results, although admitting that his primary mortality was twenty per cent.

Dr. G. B. Massey, of Philadelphia, advised electrolysis with oxychloride of mercury.

Dr. E. Kolisher, of Chicago, insisted upon a differentiation between cancer of the cervix and malignant growth of the portio vaginalis.

The paper was further discussed by Drs. J. H. Carstens, of Detroit, and Montgomery, of Philadelphia.

Dr. Baldy, in closing, stated that recurrence took place mostly in the cervical portion.

Relative Merits of the Different Methods of Uretero-Ureteral Anastomosis.—By Dr. J. W. Bovée, of Washington, D.C. The experimental work done in this field on dogs had been more unsuccessful, the speaker held, than when the same operation was performed on human beings. The history of thirty-three cases, collected from the literature, operated upon by various methods, with perfect results, testified to this fact. There were four methods, of which the transverse end-to-end was the best for most cases.

Some Results of Ovarian Surgery with Further Report upon Intrauterine Implantation of Ovarian Tissue.—Dr. Dudley read this paper. In one hundred and ninety consecutive cases of conservative operations there had been no failures. It was very rare that hysterectomy was necessary in pelvic disease. Conservative surgery was suitable only in young persons and during the child-bearing period, and those who were able to rest after the operation. Out of one hundred and twenty-eight cases in which the subsequent history had been followed, there had been twenty-eight pregnancies. The ovary must be cut lengthwise, the cysts being opened and scraped, and the cavity stitched with fine floss silk threaded in a cambric needle. The cautery must not be used to puncture cysts. The speaker had never seen any pus form in these cases. He referred to six cases of intrauterine implantation of the ovary. The uterus was split at one horn and the ovarian graft, attached to its own ligaments, was suspended in the uterine cavity and stitched to the mucous membrane, hanging there like a polyp. In this manner the artificial menopause was obviated.

Dr. J. Riddle Goffe, of New York, said that in a hundred cases of conservative operation he had seen eleven pregnancies follow in women previously sterile.

The paper was further discussed by Dr. W. H. Humiston, of Cleveland.

Dr. Dudley, in closing, said that the sclerotic ovary was not suitable for implantation.

The Various Incisions in Different Renal Operations.—Dr. Howard A. Kelly, of Baltimore, presented a communication with this title. By anatomical demonstration, he said, it had been shown that by the ordinary incision for approaching a kidney we cut off some nerve trunks, thereby causing an area of anæsthesia over the hip. In cases of simple exploration of the kidney the operator should begin over the last rib, cut obliquely down to the fascia, divide this, and separate the rest by blunt dissection. No muscles should be cut in any incisions for removal of the kidney, but they should be separated after the manner of McBurney.

GENERAL SESSION.

Third Day—Thursday, June 6th.

Suppression of Vice in the Army.—As a matter of courtesy, Miss Susan B. Anthony was presented to the association and allowed to speak on the regulation of vice among the soldiers in our new possessions.

Rev. Annie Shaw also spoke on the interest of virtue and the suppression of vice, and referred to the memorial passed by the association of woman suffragists. She requested co-operation in the effort to regulate vice in the Philippines and other of our possessions.

Dr. L. L. Seaman, of New York City, declared that these ladies were misinformed. Statistics showed that fifty per cent. of all cases of disease in the late war were venereal, and that the number of such cases had been doubled by the abolition of the army canteen.

Reorganization.—On motion of Dr. McCormick, of Tennessee, the secretary of the association was empowered to indorse the plan of reorganization already adopted so far as it applies to State and county societies. The secretary was also instructed to open correspondence with the officers of the State societies and to report at the next annual meeting.

Report of the Executive Committee.—Dr. L. Duncan Bulkley, of New York, then presented the report of the general executive committee. Each recommendation was separately considered.

A committee was appointed to draft resolutions commemorative of the lives of Drs. Alfred Stillé, Lewis A. Sayre, Hunter McGuire, and Beverly.

Incorporation of the Board of Trustees.—The association then formally ratified the article incorporating the board of trustees.

Revision of the Code of Ethics.—An animated discussion was elicited by the recommendation that "a committee of three be appointed to revise the code of ethics with instructions to report at the next annual meeting of the association, and that the printed report of their revision be published in the *Journal* of the association not later than April 1, 1902." A motion was made to lay on the table, and as the vote on this motion could not be decided satisfactorily, a roll call was demanded. Dr. Bishop, of Harrisburg, then came to the rescue of the association by moving a postponement of the roll call until next year. The motion was carried, and the chairman accordingly ruled that the entire question had been postponed for one year.

The Medical Department of the Army.—A resolution was adopted expressing disapproval of the action of Congress, tending to degrade the medical department of the army and cripple its efficiency.

Appropriation.—An appropriation of $500 was made for the committee on scientific research, and the same sum was allowed for continuing the pathological exhibit for another year. The association gave its formal approval of a proposition to establish a psycho-physiological laboratory in connection with the Department of the Interior.

Oration on Medicine.—By Dr. N. S. Davis, Jr. (see page 888).

Officers.—The following report of the nominating committee was adopted: *President*, Dr. John A. Wyeth, of New York; *First Vice-President*, Dr. Alonzo Garcelon, of Maine; *Second Vice-President*, Dr. A. J. Stone, of Minnesota; *Third Vice-President*, Dr. A. F. Jonas, of Nebraska; *Fourth Vice-President*, Dr. James A. Dibrell, of Arkansas; *Treasurer*, Dr. Henry P. Newman, of Illinois; *Secretary*, Dr. George H. Simmons, of Illinois; *Board of Trustees* whose terms expire 1904: Dr. T. J. Happell, of Tennessee; W. W. Grant, of Colorado; John F. Fulton, of Minnesota; *Judicial Council:* Drs. George Cook, of New Hampshire; H. H. Grant, of Kentucky; John B. Murphy, of Illinois; Philip Marvel, of New Jersey; Louis H. Taylor, of Pennsylvania; John L. Dawson, of South Carolina; N. Fred Essig, of Washington; *Orator on Surgery:* Dr. Harry Sherman, of California; *Orator on Medicine:* Dr. Frank Billings, of Illinois; *Orator on State Medicine:* Dr. J. M. Emmert, of Iowa; *Chairman of the Committee of Arrangements:* Dr. G. F. Comstock.

Place of next meeting, Saratoga, N. Y.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 1, 1901:

	Cases.	Deaths.
Tuberculosis	286	158
Typhoid fever	25	2
Scarlet fever	505	38
Measles	329	11
Diphtheria and croup	247	50
Smallpox	64	17
Chickenpox	63	0
Cerebro-spinal meningitis	0	4

The Bacteriology of Healthy Organs.—Dr. William W. Ford, fellow in pathology, McGill University, Montreal, has elaborated studies on this subject, begun by Professor Adami and Dr. A. G. Nicholls, and has published his conclusions in pamphlet form. The results from autopsies on man were as follows: The colon, staphylococcus, and mesentericus were the common forms of bacteria found, together with a number of long, narrow bacilli like those seen in gangrene. No putrefactive organisms were isolated, and from the similar results of early and late cultures one is led to believe that at the time of death a few bacteria were scattered in the organs, which were capable of development and transplantation, rather than that there was a post-mortem passage of bacteria from the intestine, for example, into the organs. In several cases a pure staphylococcus was grown, yet a large quantity of gas was evolved from the original culture, smears made directly, however, showing many bacilli, which might either be the gas-producing colon or some pure anaerobe, overgrown by the hardier staphylococcus. Anaerobic culture in Buchner's jars revealed nothing further to solve the problem.

A Literary Moral.—The New York *Tribune* of Sunday, March 31st, quotes these remarks from the London *Academy:* "An Edinburgh correspondent sends us the following: 'Addressing his students last week on the intoxicants, Dr. Wylie, the professor of medicine in Edinburgh University, adduced an experience of his that is not without its literary moral. He was called one day to see a young man. As he was entering the house, the patient's sister exclaimed: "Oh, it's all that horrid book!" Inquiry elicited the fact that the patient's favorite reading was "Sherlock Holmes." The young man was in a very low state, and his tell-tale arm was dotted with hypodermic punctures. His admiration for the most popular paper detective had betrayed him into the cocaine habit. Taking this case as a text, Dr. Wylie permitted himself a sentence or two of severe stricture on Conan Doyle's knowledge of the action of drugs: "If such a man as Sherlock Holmes had existed, dosing himself as depicted by his creator, in a few weeks his opinion on anything would not have been worth having." Cocaine, according to Dr. Wylie, is even more disastrous than morphine. "It renders its subject vainglorious and pleased with himself, but blunts the intellect and blasts the imagination." '"

Nursing the Insane.—At the graduating exercises of the Training School for Nurses of the Manhattan State Hospital, held on May 22, 1901, Dr. Frederick Peterson, commissioner in lunacy, made the following remarks: "I remember less than twenty years ago observing the inauguration of the first training school for asylum nurses in the State of New York, and I believe this was the second school of the kind in the United States. I understand now that there is scarcely a hospital for the insane in the country which does not give some degree of training to its attendants. The result has been a higher standard of intelligence and character required in the applicants for admission to the training schools, a vastly improved body of attendants, and a correspondingly better kind of treatment and care for the unfortunates placed in their charge. Indeed, they are no longer attendants merely, but nurses in every sense of the word. This speaks well for the progressive spirit of the superintendents of the asylums, who are always quick to perceive the value of new ideas and to seize hold of new possibilities in the evolution of the modern asylum. Nursing the insane is a delicate, difficult, and often perilous vocation. It demands an unusual number of virtues. It demands courage, self-poise, patience, sympathy, tact, kindness, and loyalty to superiors, to an extreme degree. Few in the outside world appreciate the arduous nature of this occupation. Those who read the criticisms often made of asylum nurses in sensational newspapers have no means of knowing the other side of the story. They never hear of the good things they do. They do not learn of the hundreds of thousands of insane who have been and are in charge of a vast body of nurses—painstaking, faithful, hard-working, humane, and brave. They do not learn of the thousands who have gone home from the hospitals cured, and of the thousands of grateful letters sent by these patients to those who cared for and guided them through their brain disorders. You are like an army of soldiers, in which there are some who desert, some who are disloyal, and some who are cowards, but the great body of them stand by their colors and follow their leaders to victory or defeat. The world knows little of you, of your good work, of your feats of patience and valor. I wish I had eloquence to tell the public of your good deeds. I should like to tell the story of an attendant whom I knew who followed an insane man, bent on suicide, from block to block of floating ice in the Hudson River on a biting winter's day and brought his patient safely back to shore. I would tell of another who caught a suicidal melancholiac as he was jumping out of a fourth-story attic window, and clung to him over the window-ledge with all of his strength, while two of his own ribs were being broken by the pressure, until help arrived that saved them both. Such instances could be multiplied by the experiences of every asylum

physician. I should like to write the story of—let us call her Mary Smith—a woman who for many years had charge of the maniacal ward of an asylum. There were thirty-five or forty patients in a crowded ward. Nothing can describe the noise and uncleanness, destructiveness, violence, assault, profanity, obscenity—it was a veritable hell upon earth. This nurse ruled the ward during all those years, patient and serene, a ministering angel. She never lost her temper, never said an unkind word, but preserved throughout her years of nerve-racking and depressing work a gentle and courageous spirit, never uttering a word of complaint though she grew old at her task. Deeds less heroic than these have been rewarded with the Victoria cross. And this leads me to add that I hope the day is not far distant when means will be found to show appreciation of such heroism and self-sacrificing lives among our asylum nurses by the presentation of some special form of certificate, diploma, ribbon, or medal, as a recognition on the part of the public of the same virtues for which we reward the soldier—loyalty, devotion to duty, courage, the voluntary offering of one's life for another."

Production of Bacterial Disease in Rats and Mice.—In April, 1900, Professor Danysz, of Paris, published in the *Annales de l'Institut Pasteur* an account of a micro-organism pathogenic to rats, whether given in their food or by subcutaneous infection, and presenting some resemblance to Loeffler's "mouse typhus" bacillus and to the bacterium coli bacilli, which, having once passed through an animal, killed rats in from seven to twelve days; but by successive passages through animals their virulence diminished, and finally disappeared altogether. Professor Danysz was very successful in experiments which he made on a large scale for the destruction of rats in drains by this means, for the dead rats were eaten by the others, and thus the disease was spread. With a view to test the applicability of the method for the destruction of rats in time of plague, Dr. P. Kister and Dr. P. Köttgen, of the Public Health Institute in Hamburg, have made a number of observations, which are published in the *Deutsche medicinische Wochenschrift* of May 2d. They found, like Professor Danysz, that the virulence of the bacillus for rats diminishes with successive passages through the animal organism, and after about ten passages it no longer causes death. For their experiments they grew five cultures from the heart blood of dead animals on agar plates. The weight of an agar-plate stroke-culture mass of twenty-four-hours' growth was about 9 mgm., and a rat was, on an average, given bread soaked in fluid containing one of these. These rats, after they had eaten the whole of the bread, were put in a cage with a large number of healthy rats. The latter did not fall ill if the infected rats, as they died, were immediately removed from the cage, but if food were withheld so that the dead rats were eaten by the others, the disease immediately spread, and the rats infected from the dead bodies died in about the same time as those which were fed on the bread to which the cultures were added. Fowls, cats, dogs, and guinea-pigs, to which the bacilli were administered, suffered from no symptoms of the illness whatever. The rats killed in this way never showed the swellings of the lymph glands or hemorrhages into the internal organs and into the subcutaneous connective tissue which are almost invariably found in rats that have died from the plague.

The Growth of London and New York.—The census returns for the city of London, which have recently come to hand, afford a basis for comparison between the two great cities of the old and new worlds. In each there has been a rapid increase during the past decade, but there is something prophetic of the future in the fact that not only has the rate of increase in New York City been very much greater than that in London, but that the actual increase has been two hundred and fifty per cent. greater. In 1891 the population of London was 4,433,220, and in 1901 it has increased to 4,803,342, an increase in ten years of 370,122. In the year 1890 the population of what is now Greater New York was 2,492,591, and by the year 1900 it had increased to 3,437,202, an increase during the decade of 944,611. Fifteen years ago London was growing at the rate of 50,000 a year, whereas the increase of the past decade averages only slightly over 37,000 per year. As against this, a comparison of the census of the last two decades in this country shows that Greater New York increased from 1,901,000 in 1880 to 2,492,591, an increase of 591,246, or 31 per cent., while the increase of 944,611 was at the rate of 37.8 per cent. Assuming a rate of only 40 per cent. during the next ten years, the population in 1911 should be equal to that of London at the present time. It is likely, however, that the rate of increase will be nearer 50 than 40 per cent, and, should the rate at which London is growing continue to decrease, it is quite possible that about the time the next census is taken the population will be nearly the same.—*Scientific American.*

Physical Regeneration of the Human Race.—To speak of the physical regeneration of the human race is, in fact, to talk so much frank nonsense. Alike in physical and intellectual faculty, an upward progress is traceable from the very earliest period of which science takes a reasonable cognizance up to the present hour. The principle of selection has always been recognized by nature, and the advances which have been made both in a physical and intellectual sense have resulted from unsought but inevitable conditions. We were long delayed from a knowledge of the facts under which these conditions operated by the mistaken belief that the racial elements which compose a nation were to be determined by the language employed by its population. Dr. Lagneau, in his exhaustive study of the anthropology of France, has shown that the French population is composed of the most diverse ethnological elements. Here is the list he offers: "Celtes, Aquitains, Ligures Galates, Kimmeriens, Belges, Francs. Goths, Burgundians, Saxons, Normands, Pheneciens, Juifs, Sarrasins, Maures, Grecs, Romains." Dr. Eugene Talbot, whose book on "Degeneracy" is one of the most brilliant and useful in The Contemporary Science series, proves an equally various mixture in England, and even Daniel Defoe, in his famous satire, "The True-Born Englishman," saw a part of the truth when he wrote:

> "The Pict and painted Briton, treacherous Scot,
> By hunger, theft, and rapine hither brought,
> Norwegian pirates, buccaneering Danes,
> Whose red-haired offspring everywhere remains,
> Who, joined with Norman-French, compound the breed
> From whence your true-born Englishmen proceed."

The Teutonic people are equally rich in varied ancestors, and in Austro-Hungary, where the blend is not yet truly accomplished, there are something like a score of races, speaking eleven different languages. Of all existing peoples, and probably of all peoples which ever existed, the Americans are the richest in variety of ancestry. It would appear reasonable to suppose that in the richest blending of ancestral faculty we find the richest fruition for the present and the richest promise for the future.—*London Referee.*

Shop Assistants' Hours in Australia.—Shop assistants, according to *Tit-Bits*, work only fifty hours per week. In Ballarat every shop, except those of

tobacconists, fishmongers, and hairdressers, closes at 6 P.M. for the first four days of the week, on Friday at 1 P.M., and on Saturday at 10 P.M. Work is begun at about 8:30 A.M. An hour is allowed for dinner; the total being about fifty hours' labor per week. There are also eight or ten whole holidays in the year.

Health Reports.—The following cases of smallpox, yellow fever, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended June 1, 1901:

		Cases.	Deaths.
Smallpox—United States and Insular.			
California, San Francisco	May 11th to 18th	5	
Illinois, Chicago	May 18th to 25th	7	
Iowa, Clinton	May 18th to 25th	2	
Louisiana, New Orleans	May 18th to 25th	7	
Shreveport	May 18th to 25th	1	
Maryland, Baltimore	May 18th to 25th	2	
Massachusetts, Boston	May 18th to 25th	3	
Fitchburg	May 18th to 25th	1	
Marlboro	May 18th to 25th	1	
New Bedford	May 18th to 25th	2	
Michigan, Detroit	May 18th to 25th	67	
Minnesota, Minneapolis	May 18th to 25th	9	
Winona	May 11th to 18th	1	
Nebraska, Omaha	May 11th to 18th	9	
N. Hampshire, Manchester	May 18th to 25th	5	
New Jersey, Camden	May 18th to 25th	1	
Newark	May 18th to 25th	2	1
Passaic	May 18th to 25th	1	
New York, New York	May 18th to 25th	134	13
Ohio, Cincinnati	May 17th to 24th	4	
Cleveland	May 18th to 25th	39	1
Pennsylvania, Erie	May 18th to 25th	1	
Lebanon	May 18th to 25th	8	
Philadelphia	May 18th to 25th	3	
Williamsport	May 18th to 25th	1	
Tennessee, Memphis	May 18th to 25th	6	2
Nashville	May 18th to 25th	2	
Utah, Salt Lake City	May 11th to 18th	5	
Washington, Tacoma	May 12th to 19th	1	
W. Virginia, Huntington	April 13th to May 24th	48	
Wisconsin, Green Bay	May 19th to 26th	6	
Philippine Islands, Manila	March 23d to April 13th	35	
Porto Rico, Ponce	April 27th to May 4th	5	
Smallpox—Foreign.			
Austria, Prague	April 27th to May 4th	3	
Brazil, Rio de Janeiro	April 1st to 15th	..	5
Belgium, Antwerp	April 27th to May 4th	5	2
China, Hong-Kong	April 6th to 13th	6	6
Ecuador, Guayaquil	March 30th to May 11th	..	3
Egypt, Cairo	April 15th to May 6th	..	4
France, Paris	April 27th to May 4th	..	5
Gibraltar	May 6th to 12th	2	
Great Britain, England, Liverpool	May 4th to 11th	2	
London	May 4th to 11th	1	
Scotland, Dundee	April 27th to May 11th	10	
Glasgow	May 3d to 11th	..	4
Italy, Naples	April 30th to May 12th	296	57
Mexico, Mexico	May 11th to 18th	1	
Nicaragua, Grenada	May 16th	Present.	
Masaya	May 16th	"	
Managuez	May 16th	"	
Russia, Moscow	April 21st to 27th	9	2
Odessa	April 27th to May 4th	5	2
St. Petersburg	April 20th to May 4th	21	4
Vladivostock	October 1st to 31st	1	
Warsaw	April 20th to 27th	7	
Spain, Malaga	May 4th to 11th	..	1
Valencia	April 27th to May 11th	..	2
Straits Settlements, Singapore	March 30th to April 13th	..	3
Uruguay, Montevideo	March 16th to 23d	5	
Yellow Fever.			
Brazil, Rio de Janeiro	April 1st to 15th	..	31
Colombia, Panama	May 6th to 20th	7	
Cuba, Havana	May 11th to 18th	3	
Plague—Insular.			
Philippine Islands, Cebu	April 4th	1	
Manila	March 23th to April 13th	76	64
Plague—Foreign.			
Japan, Formosa	April 21st to 28th	170	111
Turkey, Basra	May 13th	3	

Fresh Air and Consumptives.—It is interesting to learn some of the results already achieved at the Durham County Consumption Sanatorium, recently opened in Weardale, England. In an interim report on fifteen cases treated during the nineteen weeks of the establishment of the institution at the end of 1900 the medical superintendent said: "These fifteen patients gained on an average one and a half pounds in weight per capita each week, and at the same time their walking powers very greatly increased. The walks are extensive and varied, and are along sheltered roads, by running streams, through woods, up hills rising seven hundred feet, and across heather-clad moors fourteen hundred feet above sea-level. Almost all the patients remained out of doors the maximum amount of eleven hours and a half each day, and slept with their French windows wide open all night."

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

A NOTE ON THE SPREAD OF YELLOW FEVER IN HOUSES.

EXTRINSIC INCUBATION.

By H. R. CARTER, M.D.,

SURGEON, MARINE-HOSPITAL SERVICE.

It is well known that when a case of yellow fever develops in a house, the house (or its contents) may become infected, *i.e.*, endowed with such properties that people susceptible to yellow fever may contract the disease by visiting or residing in the house. Now, there is evidence to show that a certain (not inconsiderable) time from the development of the infecting case of yellow fever passes before this property of communicating the disease to other people is attained by the place.

It is not meant that the presence of the patient for that time, or even at a certain stage of the disease after the beginning (analogous to what we probably have in smallpox), is necessary to contaminate his environment. There is evidence to the contrary. For instance, at Lauderdale, Louisiana, an isolated way station on the T. & P. R. R., the agent, Mr. L., developed yellow fever (contracted elsewhere) October 8, 1897. He began work as usual that day; complained of malaise during the day, but stayed in his office attending to his work until the evening, then went to a shanty some distance off and reported sick next morning. He died. The house was vacated, and, I think, burned. His successor, Mr. B., used the same office during the day—it not being considered contaminated by so slight and so short an indisposition—but lived in a section house about a mile farther off. During the night of November 8th, or early morning of the 9th, this man sickened with yellow fever, having been apparently well when he went to bed. He in the early morning took the train for Donaldsonville, where he died November 13th. Being now afraid of the office his successor, McG., moved the telegraph instruments down to this section house, making it both office and dwelling-place. He developed yellow fever December 4th, and died December 11th. These were the only cases in the neighborhood.

Here we have in the first case a patient sick less than a day in the office, infecting it, and a subsequent occupant (working in it continuously) developing yellow fever from it twenty days later. In the second, a patient sick not over half a day in the section house, infecting it so that a subsequent occupant, living and sleeping continuously in this house, developed yellow fever twenty-five days thereafter. In both cases, then, the houses showed infection, although the patient's stay in them was very short, and only in the beginning of the disease.

Nor do we mean that the infection of the house is at first slight, and gradually, from new increments from the patients or otherwise, increases, and that the escape from fever of those living in the house soon after the introduction of the infecting case is due to the slight degree of infection, and that the development of yellow fever in those living in, or visiting it, later is due to the increased degree of infection.

Of course, in any disease in which the patient infects his environment, the degree of infection of the environment increases with the length of time the sick man remains therein. If the cause of disease be a saprophytic micro-organism, and the environment furnishes a suitable culture medium, the infection also increases with the time since the first contamination of the environment, whether that contamination be continuous or not. With such diseases, then, the chance of contracting the disease from an environment is less soon after the development of the case which infects it than later, and this chance is approximately proportioned to the length of residence of the patient and the time since his introduction. In other words, of susceptible people visiting the house at different times a lesser proportion of those who go there soon after the introduction of the infecting case will contract the disease than of those who go there later, and this proportion will, for a short time at least, be proportional to the length of time after the introduction of the primary case.

What we have observed in yellow fever does not seem capable of this explanation. None of those visiting or living in a house only up to "—— days" after the development of the primary case, and not afterward, contracts yellow fever, while many so exposed afterward do. There is no gradual increase with the increase of time of the proportion of those exposed who contract it. On the contrary, the secondary cases generally appear more or less in a group after a considerable interval from the primary case. For instance:

Mrs. A. and E., a young child, came from Ocean Springs to a country house in North Mississippi, near Edwards. Mrs. A. developed yellow fever the day of arrival, August 8, 1897, and E. the next day. There were twelve persons in the family. No other cases occurred until the night of August 21st, over thirteen and one-half days, when one other member of the family sickened, and by the 26th all ten had developed yellow fever.

S. W. G. developed yellow fever, contracted elsewhere, in a country house in North Mississippi, on August 6th. No other case developed until August 23d. Yet by August 25th five others besides the one on the 23d had developed yellow fever. These were all that resided in the house.

The above are typical examples of the spread of yellow fever in hot weather in a house where no precautions are taken, and to the writer seem not explicable by a gradual increase of the degree of infection from the development of the first case. It is rather as if the houses were at first incapable of imparting infection to those exposed to it, which property was acquired (developed) later. Let us assume this to be true, and call this period between the contamination of the house by the patient and its becoming capable of imparting the disease to those exposed to it, "the period of extrinsic incubation." This expression (from A. Corre) is fairly suitable, as it represents the time during which the infection derived from the patient is present,

but not patent in the environment; just as the infection derived from the environment is present but not patent in the patient during the time of his "intrinsic (?)" incubation. No likeness is predicated between the processes.

It is the time taken for such an evolution of the infection, derived from the patient, as renders the environment patently capable of imparting the disease to other men.

We have said "there is evidence to show" that a certain time elapses from the development or introduction of the first case before the disease can be contracted from the environment. The nature of the question admits of only negative evidence. The most that can be expected is to show that susceptible people visiting or living in a house during —— days after the development of a case of yellow fever therein, and not after that time, do not contract yellow fever. Evidence of this kind is cumulative, and is convincing only if in considerable mass. So far as a few cases of people visiting a house under the condition named and escaping fever is concerned, the evidence is of little value. The houses may have escaped infection altogether—this is common enough; or the house having been infected, the people, although exposed to infection, have not contracted fever at this exposure. This also is common. Yet the only way to show that a place cannot communicate disease is to show that it does not, opportunity being offered, communicate it; and, if we find many such instances, the evidence becomes of more weight, especially if developments show the house to be infected later and the people susceptible. If in addition we can find no case in which the contrary takes place, *i.e.*, no person developing yellow fever who has been exposed to an environment only under the above conditions, we have supplied all of the evidence which the question admits, and it is convincing in proportion to its mass.

I. Let us take first a class of cases, viz., those that occur on vessels at quarantine stations after disinfection. These cases occur aboard ship, and the vessel is disinfected again and kept under observation —— days from this second disinfection. As a rule, but a short time elapses between the development of the case and the second disinfection of the vessel. Yet some time elapses, especially if they develop in the early night and other vessels are at the disinfecting wharf, etc., or, as has happened, when the diagnosis is not made at once; and, as we have seen (vide the Lauderdale cases), the presence of a patient is needed but a little while to contaminate an environment. Yet no cases of yellow fever have developed at quarantine from exposure to infection left by these cases.

Here we have a number of people—from six to seventy-five in each instance—exposed to an environment shortly after the development therein of a case of yellow fever, the time of such exposure being from, say, half a day to five days. Yet the records of five such vessels (seven cases) at the Louisiana quarantine—one disinfected three days after development of the case of yellow fever; of one at the Tampa Bay station, and of five treated by the writer, one disinfected three and one-half days and one five days after disinfection—give no case of yellow fever contracted from infection induced by these cases.

II. In the same class must be included the cases in which houses are disinfected soon after the occurrence of a case of yellow fever. In the little epidemic at Orwood in 1898 an opportunity was offered to do this in a few cases. I quote from Assistant Surgeon Von Ezdorf's report:

"An attempt was made to disinfect houses where the disease had occurred in one or two of the family, to prevent secondary infection. This was done in five houses. One house was re-infected"—by a new case contracted elsewhere—"twenty-eight days after the disinfection. All were successful. Six foci were thus destroyed before secondary infection."

1.	One house,	5	in family,	1	sick,	no recurrence.
2.	"	"	9	"	1	"	"
3.	"	"	5	"	1	"	"
4.	"	"	8	"	1	"	"
5.	"	"	3	"	2	"	"

Here we have five houses in each of which yellow fever had occurred disinfected soon afterward, and with no subsequent developments, although they aggregated twenty-four non-immune inmates; while in the other houses of this community, the fever once introduced generally spread through the family, extremely few escaping.

With these should have been grouped two houses similarly treated at McHenry, Miss., and with the same result, but the notes of which have been lost. Nor is the interval between the development of the case of fever and the disinfection known for these houses save in two cases.

For house No. 4 it was seven days and for one (which one is unknown) two days.

The writer had advised him (Von E.) to disinfect to prevent secondary cases up to ten days, but to make the interval as short as possible. It was found, however, impracticable, save in one instance, to disinfect until the patient was convalescent, as the family were afraid to have the patient moved into a tent in the beginning of his sickness. It will be safe to put this interval, then, as between four and ten days for the other three.

The expression "secondary infection" is evidently used to mean that condition of the house in which infection can be contracted by one visiting or residing in it, the so-called "secondary" cases.

Note that the evidence here is not only that five houses where yellow fever had existed were disinfected soon after development without secondary cases, but also that in no house (although only five) disinfected soon after the development of the first case did secondary cases arise.

III. There are some instances of people visiting or living in houses in which yellow fever occurred, moving away soon after.

(1) C., an Italian tailor, developed yellow fever at Franklin, La., October 7, 1897, and died October 13th. On the 14th, eight days after, the inmates of his house—nine in number—were moved from the house and placed under observation and the houses adjacent vacated. None of these people developed yellow fever. A case, which was followed by another, occurred in a house across the street, which was narrow, October 22d or 23d.

(2) C. L., of the same town, developed yellow fever October 20th, and died the 26th. On the same day—six and one-half days after inception of his case—the five inmates of his house were moved and placed under observation and the house and the adjacent houses vacated. None of these people developed yellow fever. Two cases developed in a house just back of it, to leeward.

(3) S. W. G. developed yellow fever at a country house at Orwood, Miss., August 6, 1898. A number of people visited this house. Of eight that we could trace who visited it prior to August 16th and not afterward, none developed yellow fever, while of thirty-four people there subsequently visiting or residing thirty-three developed yellow fever; three, however, had other exposures.

(4) Mrs. T., Orwood, Miss., developed yellow fever August 31st; Mr. T. on September 1st. Both contracted the disease elsewhere. There were ten in the family. All the children were in the house, of two rooms, until September 6th, the three youngest in the

room with the two sick people. At this date—six days after the first case—five of them were isolated from the house. None of the five developed yellow fever, while the three who remained all did so.

(5) Col. R. developed yellow fever, contracted in Edwards, Miss., on September 16, 1897, in a country house. The diagnosis was made on the 17th; the next day all of the family left save four. None of the ten who left developed yellow fever. All of those who remained did so: the first three, seventeen, eighteen, and nineteen days after, and the fourth later.

(6) D. C. developed yellow fever, contracted elsewhere, September 10th, 10 A.M., at a country house near Orwood, Miss. The family consisted of eight persons. The house was burnt and everything disinfected September 17th. None of the remaining seven, who had all been residing continuously in the house of two rooms, developed yellow fever.

(7) Dr. W. developed yellow fever August 27th, in Water Valley, Miss. There were ten persons in the family. September 1st, all save Mr. W. left and went into the country. None developed it until they returned to the house September 24, when all of them developed yellow fever; the first three days after return. This house had been disinfected just prior to the return of these children, but unquestionably not successfully.

(8) With these single houses we should group the results of the little "Observation Camp" at Jackson, Miss., in 1899. In this camp were received only the inmates of houses in which a case of yellow fever had occurred, and the attempt was made to get them to come away from their houses as soon after the development of the case as practicable. Many came within the first two or three days. Not a few cases of yellow fever, however, were not diagnosed for a few days, and in not a few others the family declined to accept the diagnosis, or failed to realize the gravity of the disease until several days had elapsed and the patient was very ill or dead, when they would come out to the camp. Forty-nine persons, all white, came to this camp, all, as stated, from houses in which yellow fever had occurred. None of them developed yellow fever. None of them were expected to do so. Yellow fever developed in a certain number of the houses from which these people came among those remaining to care for the sick; although this was done by immunes as far as possible. People were not taken from houses in which cases had been contracted.

IV. Finally, there is the large and, to the writer, convincing class of observations of the spread of yellow fever in a house (or vessel) infected by some one who has contracted the fever elsewhere developing the disease in (or aboard) it. It is necessary for these observations that we know: (1) The dates of development of the infecting and secondary cases; (2) that the inmates of the house have resided there continuously from the development of the first case to their own sickness; (3) that they have been exposed to no other source of infection, save at their own premises. And all these things must be known beyond cavil. In all cases fulfilling these conditions there is a considerable interval of time between the infecting and the first case contracted in the house; then such secondary cases come rapidly, sometimes in a bunch. The two instances in the first part of this paper are typical. Here are a couple more:

(3) M. C. developed yellow fever at Nitta Yuma, Miss., September 11, 1897, at Mr. B.'s house. Mrs. B. developed yellow fever September 27th at night, Miss T. on September 28th, J. S. on October 1st, Miss B. on October 2d, Mr. B. on October 6th, Mrs. S. on October 8th, and J. P. on October 8th.

(4) C. H. P. developed yellow fever at Nitta Yuma, Miss., October 8, 1897, in Mr. D.'s house. J. D. developed it on October 21st, H. D. on October 21st, J. T. R. on October 21st, M. J. E. on October 23d, S. S. on October 23d, Mrs. D. on October 24th, and R. D. on November 24th.

Of these four houses, the interval between the first (infecting) and the next (secondary) case is, for Mr. A.'s house, 13½ or 13¾ days, and then 10 cases in 5 days; Mr. G.'s house, 16½ days, and then 6 cases in 2½ days; Mr. D.'s house, 13½ days, and then 6 cases in 3 days and 1 later; Mr. B.'s house, 16 days, and then 4 cases in 6 days and 3 later.

The writer made a study last winter (*New Orleans Medical and Surgical Journal*, May, 1900) of the spread of infection in houses at Orwood and Taylor, Miss., fulfilling the required conditions. The findings were all similar to the above, and are here reproduced in tabular form:

TABLE I.

House.	Infecting case.	First secondary case.	Interval in days.	Number of secondary cases	Number of people in house.	
Orwood—						
1.....	Aug. 6th	Aug. 23d...	16½	6	7	First secondary case was in existence Aug. 22d, 5 P.M., interval 16 + days.
2.....	" 29th	Sept. 13th..	15	3	4	All developed in one day.
3.....	" 28th	" 18th ..	20	4	5	
4.....	Aug. 31st and Sept. 1st	" 20th ..	19½	5	7	Two infecting cases.
5.....	Sept. 3d.....	" 26th .	26	6	7	
6.....	Aug. 31st.....	" 22d...	21½	4 or 5	6	Source of infection in one secondary case doubtful.
7.....	Sept. 4th	" 20th ..	16	2	?	
8.....	" 2d.....	" 22d ..	20½	1	?	
9.....	Aug. 29th, 30th	" 9th ...	11½	1	3	Two infecting cases. Interval 11 days 15 hours.
Taylor—						
10.....	" 7th.....	Aug. 27th ..	20	13	14	
11.....	" 17th.....	Sept. 2d	16	8 or 10	11	All in house had fever, but two may have contracted it elsewhere.
12.....	" 10th, 11th	Sept. 25th or " 28th.	15 or 18	3 or 2	5	Two infecting cases; one secondary case may have contracted it elsewhere.

House 1 is Mr. G.'s home mentioned before in this paper.

In addition to the above, the writer has records of a few other houses and a few vessels: these will not be given, but wherever he has been able to trace the spread of yellow fever in a house which fulfils the conditions I have mentioned, the existence of this interval, not less than 11½ days, usually over 14 days, has been found. Now this interval is habitually greater, and considerably greater, than the period of incubation of yellow fever. For instance, in the Gray house at Orwood the minimum interval is 16 days, while the period of incubation observed by the writer of six cases contracted about the same time from a single exposure at this house were 3¾ days, 4 days, 3 days, 3½ or 4 days, 3 days, 5¾ days, respectively. It is obvious that yellow fever was not contracted by those residing in this house for a considerable time after the development of the first case, for there is no reason why these six residing in the house from the beginning should have an incubation of from 16½ to 19 days, and the six who visited the house once afterward should have incubations of from 3 to 4½ days.

But the above statement is general. In all cases which I have been able to observe, the interval between the infecting case and the first secondary case is habitually considerably greater than the period of incubation of yellow fever.

Yellow fever, then, is not contracted in any of these houses by those residing continuously in them until a considerable time (in days) after the development of the infecting case, although these same inmates do contract the disease from the same houses later. This

latter fact, as I said at first, strengthens the position that at first, when none took the disease, the house was not capable of transmitting it, and that later it became so. To sum up:

I. Cases of yellow fever which occur aboard ship after disinfection at maritime quarantine stations have not been followed by any others among the crew.

Eleven vessels disinfected from "at once" to five days after the first case.

II. Cases of yellow fever which occur in houses disinfected soon after occurrence were not followed by other cases among the inmates.

Five houses—twenty-four susceptible inmates—disinfected, one seven days, one two days, and the rest probably four to ten days after first case.

In no case has the contrary been observed.

III. Cases of yellow fever which occurred in houses vacated soon after have not been followed by other cases among the inmates leaving, although cases occurred among those who remained in the houses or in the neighborhood.

From seven houses forty-six inmates were removed from two to eight days after development of the first case. In no case has the contrary been observed.

With these consider the forty-nine people moved from houses in which yellow fever had occurred to the Jacksonville "Observation Camp"; none of whom developed yellow fever.

IV. Cases of yellow fever which occur in clean houses are not followed by other cases among the inmates exposed to no other infection until after such time as shows that the disease was not contracted for a number of days after the development of the first case, although these same inmates do develop yellow fever from these same houses later.

Fifteen houses, with eighty-one susceptible inmates subsequently developing yellow fever, here reported; others have been observed. In no case was the contrary observed.

As before said, the class of evidence here presented is convincing in proportion to its mass. Whether it is enough to convince, the reader must determine. Yet, in the writer's opinion, the phenomenon of the "interval" in house infection is itself sufficient.

It may be that the force of this may be plainer if the full history of one such "house infection" be given in detail. We will take one already mentioned in this paper:

House 1: Gray House, Orwood, Miss., 1898: S. W. G. developed yellow fever (contracted at Taylor's) August 6th, 11 P.M. L. G., roommate of the above, August 23d, 11 A.M; A. G., August 24th, 11 A.M.; S. G., August 24th, 7 P.M.; C. G., August 25th, 2 A.M.; C. G., August 25th, 12 midnight.

All the above were inmates of this house, and were the only inmates living there continuously up to the 25th.

In addition the following cases were contracted here by visitors and others:

1. L. O. spent the evening here August 18th, single exposure; developed yellow fever August 22d, 5 P.M. 2. G. M. was at this house 2 to 6 P.M. August 25th, single exposure, developed fever August 29th, noon. 3. P. S. was at this house several times August 25th to 28th, developed fever August 29th. 4. P. R. was at this house night of August 25th, single exposure, developed fever August 29th. 5. M. O. was at this house August 24th and 27th, developed fever August 30th, 1 A.M. 6. J. R. was at this house nights of August 25th and 27th, developed fever August 30th, night. 7. W. S. was at this house August 25th, 28th, and 30th, developed fever August 30th, night. 8. J. T. was at this house August 25th and 30th, developed fever August 31st. 9. A. J. was at this house night of August 27th, single exposure, developed fever August 31st, morning. 10. G. L. S. was at this house August 25th, 26th, and 27th, developed yellow fever August 31st. 11. H. S. was at this house several times to August 30th, developed fever September 1, 2 A.M. 12. Mrs. J. T. was at this house August 29th (10 to 4 P.M.), single exposure, developed fever September 11th, 4 P.M. 13. Mrs. I. C. was at this house August 29th (10 A.M. to 4 P.M.), single exposure, developed fever September 2d, 4 P.M. 14. W. M. W. was at this house August 27th and 29th (in evening), developed fever September 2d, 1 A.M. 15. M. K. came to nurse August 28th, 1 A.M., developed fever August 31st, 2 A.M. 17. M. C. came to nurse August 27th, 6 P.M., developed fever September 1st, 9 A.M. 18. G. S. came to nurse August 29th, 9 A.M., developed fever September 2d, 3 P.M. 19. P. D. (colored) came to the house to nurse August 27th, 7 P.M., developed fever September 3d, 2 A.M. 20. Dr. M. visited the house on the evening of August 29th, returned August 30th, and was continuously exposed to date of his illness, September 3, 8 A.M.

This list includes nearly all, non-immune to yellow fever, who visited this house about this time. Of the remainder, one physician developed yellow fever August 27th, but may have contracted his disease elsewhere. His successor was Dr. M. above. A third relieving him succumbed later in the season, date not known. Of three friends who had been at the house at intervals since August 25th, dates not known, two sickened September 6th and 7th respectively, and the third escaped infection from her visit, the only person known to have done so.

Now here are twenty people, fifteen visiting and five living, in this house from August 18th to September 4th, all developing yellow fever by the latter date. Note that six of them were of a single exposure, incubation of from three to five and three-quarter days; and that the exposures of the rest were not prolonged or often, yet all developed fever, and all developed it within a few days after their first exposure; and that the three whites who entered the house to nurse developed fever within from three to four and one-half days, as did the physician. Yet the six habitual inmates of this house lived there with no sickness from August 6th to 23d. Obviously the condition of this house as regards power of communicating disease must have been very different soon after August 6th from what it was, say, from the 20th on. Taking into consideration the bunch of cases among these inmates from the 23d to the 25th, and the fact that nearly every one who visited this house at this time and after developed fever within a few days, whether he had one exposure or more, one is led toward the conclusion that this house was not capable of imparting infection for some time after the development of the infecting case on August 6th. Since all such houses give the same finding, although few so flagrantly as this one, the conclusion seems to the writer justifiable and the point proven. Because, although one may be exposed to infection many times without contracting disease, and yet contract it on another exposure, yet, if a large number of people under varying conditions be exposed for a considerable interval of time, some of them will contract it at such exposure. Conversely, if of a large number of people thus exposed in a certain place none contracted the disease, it is fair to say that the place is not capable of communicating infection. Certainly there is no other evidence possible.

I have not attempted to determine the time of extrinsic incubation. I have not the data to enable me to do so definitely in any particular case. Suffice it to say that "while it takes but a short time—less than a day—after the development of a case of yellow fever for a patient's environment to receive infection, yet it requires a considerable number of days before

this environment is capable of imparting yellow fever to other men."

The observations on house infection, the most definite bearing on this subject seem, however, to give us a clew. We have noted the "interval" from the infecting case to the first secondary case as being usually considerable. and have determined it in a number of cases. Now, the interval from the infecting case to any secondary case from it is composed of the sum of three periods: (1) The period of extrinsic incubation for the environment; plus (2) the time the individual in question was exposed to infection before he contracted the disease; plus (3) the period of incubation of the secondary case. In the general case all three are variants: the middle term depending on individual exposure and individual susceptibility to the disease.

Yet where there are many secondary cases—as in house No. 9, Table I., thirteen cases—this term in the interval to the first secondary case should become small, because of so large a number contracting yellow fever in a house, some one of them must have contracted it soon after exposure. The argument is stronger when we consider five houses (see Table II.) having a total of thirty secondary cases, with an interval of sixteen days (fifteen and one-half to sixteen and one-half days) between the infecting and first secondary case.

Surely here the middle term must be small; some one of these thirty cases exposed to five different sources of infection must have contracted fever very soon after exposure.

As the usual limits of the period of incubation, the last term of the sum, are fairly known, it is evident that a knowledge of this "interval" in a sufficient number of instances is sufficient to determine approximately the usual period of extrinsic incubation.

I have found the interval between the infecting and the first of the secondary cases in a house as nearly always over fourteen days; while later these same houses give periods of incubation of from three to less than six days; and when people go to visit or reside in them some of these people, usually several, develop yellow fever in the same time, less than six days, from the first exposure. From this I would place the period of extrinsic incubation as generally not less than ten days; indeed, it may fairly be placed somewhat higher; as there are few instances in which any inmate of such a house has contracted yellow fever within ten days from the introduction of the infecting case. Its limits, doubtless, vary, but probably not very considerably—the intervals between the infecting and the first secondary case (when there are many secondary cases) do not. The inferior limit is probably not far from below the ten days which I have suggested as generally the minimum.

The following table of "intervals," most of which have been given in detail elsewhere, illustrates this—fractions of days have been omitted:

TABLE II.

Number of houses	Interval in days.	Number of secondary cases.	
1.....	12	1	11 days, 15 hours.
1.....	13	6	
1.....	14	10	13¾ days.
2.....	15	5	One may have been 18 days.
5.....	16	30	
1.....	18	7	
1.....	19	5	19½ days.
2.....	20	17	
3.....	21	8	
1.....	23	6	

From this, from ten to seventeen days after the development of the infecting case, seem to be about the usual limits for contracting the disease by the first of the secondary cases, when there are many of such cases in a house.

It is understood that the above determination of the period of extrinsic incubation is tentative and approximative only.

There is a practical application of this doctrine. When a case of yellow fever develops at a maritime quarantine station, aboard a vessel after disinfection, and the vessel is disinfected promptly (within a few days), she need not be detained longer than to cover the period of incubation from the first disinfection, instead of from the second one as has been the case. The second disinfection being done before the vessel is capable of imparting infection to men, the completion of the first disinfection was the last exposure of any of her personnel to a chance of contracting the disease, and from this the detention should date. Similarly, when a case of yellow fever develops in a clean house, the inmates of this house who leave within a few days (if exposed to no other source of infection) may be permitted to leave without quarantine detention, for they will not develop yellow fever.

Since writing the above, the experiments of Major Reed at Quemados have been published. It is obvious that what we have here called "the period of extrinsic incubation" is the time he finds to elapse from the infection of the mosquito by biting a yellow-fever patient to the time it, the mosquito, becomes capable of communicating the disease to man. This he places definitely, in his experiments, at not less than twelve days, and up to eighteen or more days; somewhat in excess of my probable finding. Yet the agreement in time is fairly close, and Reed's theory agrees absolutely with the conclusions of this paper. Under it the disease could not be contracted in a house until this number of days had passed since the mosquitos had access to the patient.

As is natural, experiments which one makes, and of which he controls all the conditions, give conclusions much more definite, and hence more valuable, than we are apt to obtain by observing never so painstakingly experiments which are accidentally made for us in the ordinary course of an epidemic.

ON THE ORIGIN OF CANCER: WHAT REMAINS TO BE DEMONSTRATED.

By SAMUEL W. BANDLER, M.D.,
NEW YORK.

REFERRING to the recent results reported by Gaylord with regard to the injection into animals of cancer tissue and juices, and peritoneal fluid, Cullen says: "We fail to find a single instance where there is conclusive evidence of a pure culture of a germ being employed."

"The third requirement (to recover the organism from the cancer thus produced) is barely touched upon, and no proof of its successful accomplishment is adduced. In justice to Dr. Gaylord, it must be added that the above-mentioned article is a preliminary communication, and that the completed work may solve many of the still obscure points." It may, therefore, be in place to consider these two points, in order to determine what questions are to be decided in the final report, and to make clear the basis on which a definite decision must then be made.

Parasitic yeasts and blastomycetæ have been found by various investigators in different pathological affections. Cultures have been obtained, but not in all instances. In the pus of a chronic skin affection causing death, Gilchrist and Stokes found blastomy-

cetæ and large sporulating cells (16 to 20μ) from which small bodies (2μ) passed out through the cell membrane, leaving only a glass-clear structureless ring. Cultures of these so-called "cell inclusions" were obtained, but Gilchrist does not say whether he considers them to be blastomycetæ or not.

In a woman thirty-one years old who died of multiple, purulent, tumor-like inflammations in the bones, skin, lungs, kidneys, and spleen, Busse found a great development of yeast cells in these centres, and cultures were easily obtained. From four to eighty-three days after inoculation the test mice died, and yeasts were found in great numbers at the point of injection and in the internal organs, but a growth of tissue resulted only after a long continuation of the affection. Busse obtained yeast cultures from a squamous carcinoma of the skin, a carcinoma of the cheek, and a carcinoma of the lips, as well as from a vaginal sarcoma of a four-year-old child.

In a case of sarcoma of the omentum, Corselli and Frisco cultivated a yeast both from the fluid of the hydrops ascites chylosis obtained during life, and from the sarcomatous mesenteric glands obtained post mortem. The fluid and cultures caused "neoplasms" in guinea-pigs, dogs, and rabbits, but no drawings of the same are shown.

Curtis found in a myxosarcoma "cell inclusions" which, on cultivation, proved to be a white yeast, which he called saccharomyces subcutaneus tumefaciens. When injected it caused tumors composed of great groupings of these parasites, but no pathological malignant neoplasms. The same results were obtained by Buschke, and by Petersen and Exner, who examined twenty-two non-ulcerated carcinomata and sarcomata, but obtained no cultures.

Plimmer, who examined twelve hundred and seventy-eight carcinomata, found in eleven hundred and thirty "cell inclusions" which he considered to be parasitic, but only nine times were they plentiful. Only once did he obtain a culture and that from a rapidly growing carcinoma of the mamma, though, as Leopold says, no mention is made as to whether the carcinoma was ulcerated or not.

Sanfelice found in fruit juices saccharomyces neoformans, which were pathogenic for guinea-pigs. Injected into the mamma of a dog, it caused an adenocarcinoma of the mamma, and epithelial elements as metastases in the affected lymphatic glands. He injected a pure culture into both testicles of a dog, and obtained adenocarcinoma with metastatic nodules in the surrounding tissues, finding blastomycetæ in both. On injecting a pure culture into the veins of dogs he obtained connective-tissue neoplasms. A pure culture injected into the organs of dogs causes, as he finds, epithelial tumors like malignant growths as regard structure and course. He finds the saccharomyces neoformans to be of two forms in the tissues of animals, one of which has a capsule and is like the fuchsin bodies of Russell.

At the recent surgical congress in Berlin, Sjöbring demonstrated small micro-organisms with amœboid movements cultivated from a carcinoma, which, in the stained specimens, were found to be round, concentrically layered bodies with which, in white mice, he obtained "genuine epithelial tumors." Concerning the microscopical specimens O. Israel said, "There are only tissue forms, and we see only what is found in all tissue elements preserved in sterile inappropriate media, but nothing which may be called amœbæ." He considers it useless labor to seek for protozoa. Gussenbauer has known these parasites for years, but could never get cultures. Jürgen said that Sjöbring had demonstrated the same specimens previously and had considered them the cause of sarcoma. He does not believe that any weight is to be attached to them. Czerny defended Sjöbring against the accusation that he had carelessly given out as the cause of carcinoma what might perhaps be only an accidental product, by calling attention to the fact that Sjöbring has busied himself with this question for ten years.

Sanfelice was the only one who, after introducing cultures of blastomycetæ into the animal body, obtained tumors of a connective-tissue and epithelial nature which were malignant, contained blastomycetæ, and brought about the death of the animal; but these micro-organisms were not obtained from human beings.

In 1896 Rosenthal wrote "Concerning Cells with Independent Movement of their Contents found in Carcinoma, and Concerning the So-Called Cell Inclusions, based on the Examination of Fresh Material." He found (1) fatty degenerated cells, (2) granular cells, (3) glass-like bodies, (4) round cells with double contour, and filled with yellow angular or long bodies of a shining color. Immediately after preparing specimens in hanging drops for the microscope, and sometimes only in the course of such observation, a movement of the bodies in the last-mentioned cells was noted, sometimes strong and sometimes weak, but often continuing for hours and days. There was a movement of these small bodies in the cells among each other, as if cooking or boiling. At various periods these dancing bodies passed out one after the other, without any appreciable injury to the cell membrane, until finally only a pale, simple cell capsule was left behind, sometimes with a nucleus but generally as a body clear as glass. Outside of the cells the small bodies continued their movements. The question of importance was whether this was a molecular movement of broken-up changed cell elements, or whether cocci or parasites were in question. The surrounding fluid was too small to cause a movement of all the bodies in the cells, and therefore either an external chemical influence was being exerted or else, as was found to be the case, the condition represented parasites in sporulation.

These investigations, made in the clinic of Leopold, were continued by the latter, and in January, 1900, he reported cultures of blastomycetæ obtained from human carcinomata, and reported tumors caused by the introduction into animals of both human carcinomatous tissue and cultures of blastomycetæ obtained therefrom.

Leopold used carcinomata of the uterus, ovaries, tubes, vagina, external genitalia, mamma, peritoneum, omentum, etc. The material was taken from the inner portion of metastatic nodules from the "outposts" or extensions of the primary growths, and farthest from the primary ulcerating area. It was wrapped in sterilized towels, handled with sterilized instruments, and examined in sterilized fluids in a thermostatic microscope. The tissues were examined in hanging drops of sterilized bouillon for over two hundred days without contamination. No cocci or bacteria developed in the hanging drops. The tissues were also examined in caustic potash, caustic soda, hydrochloric acid, and weak nitric acid according to the method of Busse and Sanfelice. These dissolve the cell elements, but not parasites like the blastomycetæ. The "outpost" pieces were put in sterilized bouillon and in grape-sugar solution in U-shaped glasses. After a few hours, on the formation of CO_2, the fluid was poured into sterilized glasses with a little caustic potash and a few pieces of metallic iodine were added. The resulting iodoform smell proved the formation of alcohol through the action of yeasts. Pieces taken from the non-carcinomatous tissue caused CO_2, but no alcohol.

Microscopical examination of the stained specimens proved that at times the structures took no stain. This was probably due to changes occurring in the process of hardening the tissues, or else it depended on the

varying degrees of development of the blastomycetæ. The result showed uniformly the glass-like bodies with processes of sporulation and budding. The above-mentioned boiling or cooking cells are too large to be considered cocci. They are not bacteria of decomposition; for the hanging-drops, fluids, and instruments were too clean. They are not the result of fatty changes, for their forms do not change in ether, alcohol, or osmic acid. They are not degenerating cells because of the sporulation. and because they differ from other degenerating cells which are present. They are blastomycetæ.

It is interesting to observe the results obtained by Leopold in conforming with the postulates of Koch. First postulate: the demonstration of a micro-organism in the blood, juices, or tissues. Leopold believes that the above-mentioned bodies may cause malignant growths. The blastomycetæ were also found in ascitic fluid. In one case a drop from the ascitic fluid was examined in sterilized bouillon: fresh carcinomatous tissue in sterilized bouillon; fresh carcinomatous tissue in a drop of hydrochloric acid, in a drop of weak nitric acid, in forty per cent. phosphoric acid, and in caustic soda. In all these hanging drops the same structures were found, namely, glass-like bodies of a diameter of 1 to 10μ with a clear centre and a light-breaking inner ring.

Koch's second postulate: the cultivation of the microzoon outside of the body. In twenty carcinomata Leopold obtained pure cultures four times from the "outposts." In a case of carcinoma of the ovary the hanging drop was examined for months. No degeneration of the glass bodies occurred, although the increase ceased finally, as if insufficient nutrition were present. After ten months cultures were made in neutral gelatin. Within twelve days a white growth appeared on the surface. When stained with carbol fuchsin, mycelia and round bodies of 1 to 25μ with a double contour, and containing finer bodies, were found. They were like the blastomycetæ of Busse. A second culture was made in gelatin, and after thirty-seven days there appeared a growth with mycelia and some blastomycetæ. A third culture was made in somewhat acid gelatin, and in fourteen days there appeared a thick white layer, with many blastomycetæ and some mycelia. A fourth culture made thirty-six days later produced in twenty days a pure culture of blastomycetæ.

In a second case of carcinoma of the ovary six succeeding cultures were made. From the last were found in hanging drop double-contoured glass-clear cells of 1 to 3μ. The large ones contained bodies often in active motion, and many processes of sporulation and budding were observed. The same results were obtained from a carcinoma of the mamma, and from a carcinoma of the portio. When a growth of any of these four successful cultures was made in grape-sugar solution CO_2 and alcohol were always obtained, and the same result was noted with the fresh carcinomatous tissue. The above-mentioned bodies were found also in sections of the affected areas.

Third postulate of Koch: to produce the same growth by inoculating the organism into another body. The "outpost" tissue in pieces or as a mixture was introduced into the abdomens of rats, guinea-pigs, and rabbits, and into the backs of rats. The tails of rats were irritated by croton oil, and the carcinomatous mixture was rubbed in. Pure cultures were injected subcutaneously, and into the testicles, mamma, and peritoneum. A bit of a carcinoma of the portio introduced into the abdomen of a rat caused its death in one hundred and fifty-six days. On the right side under the liver, between it and the entrance of the pelvis, was found a tumor with pus-like contents, in which were blastomycetæ containing moving bodies. A portion of a carcinomatous ovary was introduced into the abdomen of a rabbit. When killed after three hundred and three days yellowish-brown bodies were found in the urine, in and about which were found blastomycetæ.

Before mentioning the next two cases I quote the following by Cullen from *American Medicine* of May 18th. "I have had the opportunity of examining some of Dr. Gaylord's specimens, and it is certain that the nodules that he produced in the guinea-pig's lungs are cancer. He, however, used peritoneal fluid, and not pure culture of the organisms. He cannot exclude the possibility of cancer cells from the patient having been carried over in the fluid to the guinea-pig, and it is a well-established fact that cancer cells may be transplanted and grow."

In his third experiment Leopold introduced the tissue from a carcinomatous ovary into two rabbits and one white rat. The first rabbit died in three days, and in the urine were found bodies like blastomycetæ. The second rat was killed after four hundred and thirteen days; in the lungs were small, yellow nodules composed of infiltrated tissue and blastomycetæ. The latter were found also in the epithelia of the smaller and larger bronchi. Yellow, double-contoured, round and oval structures containing small bodies were found, some at the base of an epithelial cell and some in the epithelial cell pushing the nucleus aside. The white rat developed in the abdomen, between the intestines, a tumor the size of a walnut filled with a thick substance, and containing some blastomycetæ. On the right thigh was found a tumor the size of a walnut containing blastomycetæ. Other cells in this tumor were found to be filled with very fine bodies. About the cells were many small bodies as if they had just been discharged from the cells. They resemble the boiling cells mentioned above. The description of the tumor was as follows: "In a loose, partly œdematous, and myxomatous connective tissue lie numerous round and long oval structures like the blastomycetæ found in human carcinoma. In this myxomatous tissue are found isolated alveolar-like groups of cells arranged in the form of strands, between which are blastomycetæ. The arrangement recalls most closely the adenomatous grouping, and if we are to give a name to the entire tumor, according to its histological structure, the one most nearly correct would be adenosarcoma infiltrated with numerous blastomycetæ." The fourth experiment of Leopold, the introduction of a portion of a carcinoma colli uteri into the abdomen of a rabbit, caused the death of the animal after four years and five months. The liver was covered with nodules, and the lung likewise with nodules of a gray-white color. These represented "epithelial neoplasms, in part atypical, and also blastomycetæ. The nodules in the lung are completed epithelial neoplasms, whose character at certain points, through the non-limited growth and the displacement of the lung tissue, may be characterized as atypical."

It is certain that these results obtained by Leopold, if we judge from the histological description, do not fulfil the third postulate of Koch. It might be claimed that the micro-organisms of carcinoma must not necessarily reproduce in animals tumors like the parent growth in the human being. On the other hand, we have the statement of Cullen to the effect that Gaylord obtained carcinoma in animals after the injection of fluid containing cancer cells. Since cancer cells have produced real carcinoma in animals, we must demand the same result on injection of the causal micro-organism, and this Leopold certainly did not obtain by introducing carcinomatous tissue. What results did he obtain by the use of cultures of blastomycetæ obtained from human carcinoma?

A pure culture mixed in bouillon was injected into

one testicle of five white rats. In one which died after one hundred and ninety-five days, bluish-red, small and large nodules were found in the abdomen. All the abdominal organs were covered with these nodules, and the diaphragm was thickened by them to 1 cm. The juice of the tumors contained blastomycetæ. The structure of the nodules is that of a giant-celled sarcoma. "In the sarcoma and intermingled between intercrossing bundles of loose, wavy, connective tissue lie connective-tissue cells of all sizes and running in all directions. The large cells (15 to 20 μ) have a swollen protoplasm; the nuclei in some cells are enlarged and six or eight may be found closely pressed together, situated especially at the edge of the protoplasm. The tumors are very rich in blood-vessels, and in cross sections of the blood-vessels many blastomycetæ are found. Many large cells are present, filled with small bodies, while others have such small bodies in their direct vicinity, as if the cells had just burst. These resemble the glass-like bodies, the blastomycetæ of carcinomatous tissue."

The value of these experiments must necessarily rest on the judgment of the microscopical specimens. This last case of Leopold, while interesting, is by no means convincing, for we must demand the production of a real carcinoma on the injection of blastomycetæ. Even though Leopold used the carcinomatous areas farthest from the points of ulceration, yet it is possible that the blastomycetæ are secondarily present, and are possibly the cause of the ulceration. The results obtained in animals by the introduction of bits of carcinoma and of pure cultures may be simply the reaction of these animals to the introduced irritation of the yeast. If these micro-organisms are the cause of malignant neoplasms, why do we find so rarely sarcomatous tumors of the ovary, of the mamma, etc.? If the blastomycetæ cause carcinoma of the cervix, why do we not find as metastases sarcomatous glands? Again, it is certain that metastases result from displaced cells, and even with no discoverable primary growths on the penis, scrotum, or lower limbs, squamous-celled carcinomata of the inguinal glands are found in chimney-sweeps.

Kossman, in discussing the origin of carcinoma, especially in the ovary, showed specimens of the latter in which both cylindrical and squamous epithelial carcinomata were found, and asks how it is possible, if parasites produce carcinoma, that squamous epithelium should appear in the ovary, and how they may produce, in the same ovary, at one point a cylindrical, and at another point a squamous, epithelial carcinoma. On the other hand, it may be stated that the introduction of carcinomatous tissue and blastomycetæ into the abdomen or into mesoderm tissue can naturally produce only mesodermal malignant growths (sarcomata). It is possible that for the production of carcinoma the action of the blastomycetæ, if they are the cause, must be exerted mainly and directly upon the epithelium, and not through the medium of the lymphatic or blood circulation, yet when injected in the testicle of animals abundant opportunity for the irritation of epithelium into carcinoma is present. It is in this connection that the experiments of Sanfelice are of interest, although he did not use blastomycetæ obtained from human beings. It is this very fact which, in spite of the results obtained, speaks against attaching a real etiological value to these micro-organisms. Besides, the large number of sarcomata and mesodermal tumors, dermoid growths, etc., especially mixed mesodermal tumors, prove an origin from displaced embryonal cells to be a fact. The occurrence of the epithelial growths from displaced cells is easily demonstrated in the female genital organs. The change of ovarian cystomata to forms histologically and clinically malignant can well be considered a continuation of the development of those displaced epithelial cells which produced the primary cystoma.

Fourth postulate of Koch: to recover the organism from a resulting like growth produced by inoculating it into another body. Cultures from the nodules of the last-mentioned case produced a white growth on gelatin which proved to be a pure culture of blastomycetæ, and from this on acid gelatin a pure culture was again obtained. It was injected into one testicle of five rats and the result is to be learned, we hope, at the gynæcological congress to be held shortly at Giessen.

The following chain has, then, been obtained by Leopold: 1. In the fresh ovarian carcinoma of a certain patient were found blastomycetæ. 2. From this fresh carcinomatous tissue a pure culture of blastomycetæ was obtained. 3. This pure culture, injected into the testicle of a rat, produced a large number of peritoneal nodules (but not carcinoma) causing the death of the rat, and in the fresh as well as in the hardened tissue were large numbers of blastomycetæ. 4. From these nodules a pure culture of blastomycetæ was obtained.

"If we are successful, on inoculation of this last pure culture into rats, in producing in them again neoplasms which are of such a character that they produce the death of the animal, then the ring is complete and no doubt can be well entertained that blastomycetæ are able to produce malignant neoplasms" (Leopold). The causal relation of blastomycetæ to the growths produced in animals by Leopold must be granted. The decision concerning the character of these neoplasms and their actual relation to carcinoma and sarcoma is to be the controversial point.

127 East Sixty-first Street.

THE REDUNDANCY OF THE PREINSULA IN THE BRAINS OF DISTINGUISHED EDUCATED MEN.

By EDWARD A. SPITZKA,

NEW YORK,

STUDENT OF MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS.

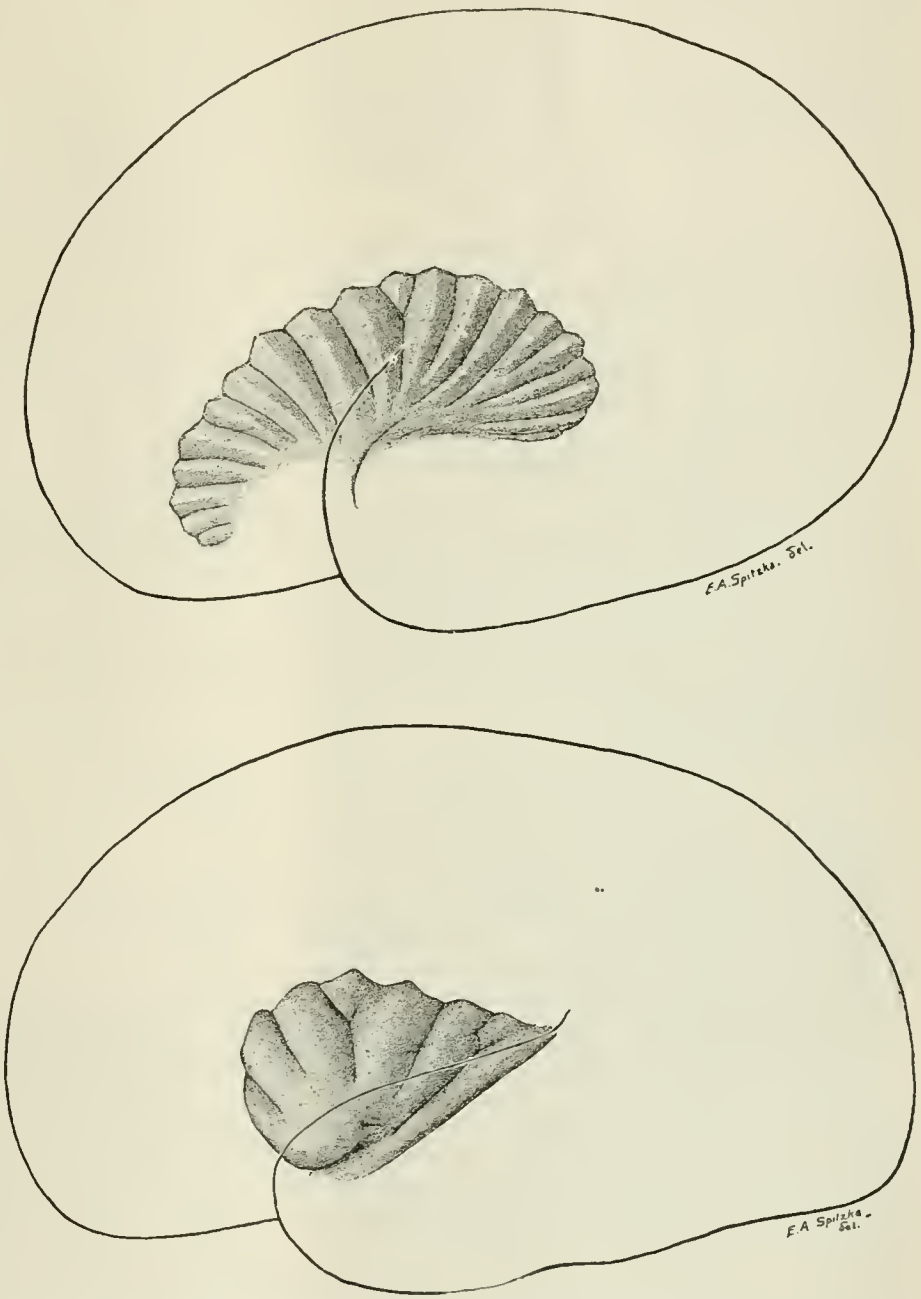
The doctrine which assigns the seat of the highest cerebral functions to no special centre, but to the orderly yet complex union of several centres through tracts of association fibres, may be regarded as universally accepted, and as a presumption underlying inquiries directed to the establishment of a relation between such function and the development of the cerebral organ. On examining the records of useful cases whose collation furnishes the clinical tests and proofs in this field, one encounters much that is unsatisfactory in regard to topography and nomenclature. As has been often urged, the analytical study of brains of moral and intellectual persons should become as extended as the consideration of the defective and criminal classes has been heretofore. The anatomical features of the human insula are of fundamental importance in the interpretation of mental states, and as much attention should be paid to its appearances in the brains of individuals representing the various intellectual grades, as to the external cerebral configurations.

Exceptional opportunities are afforded the present writer in the study of the Seguin brains (father and son)[1] with particular reference to a region whose development is related to that of the regions to which the faculty of speech is referred. The peculiarities observed upon these brains, while corroborative of an interesting statement made in 1887 by Waldschmidt, serve also to correct a misapprehension hitherto prevailing.

Most writers, such as Meynert, Cornillon, Lepine, Charcot, and others, regarded the insula as the corti-

cal centre of speech. Even at so late a period as 1883, Charcot [2] goes so far as to say that certain cases tend to show that exceptionally the insular cortex presides over this faculty, to the exclusion of "Broca's convolution," or subfrontal gyrus. Four years before, Clozel de Boyer[3] asserted that the speech centre was not limited to the subfrontal gyrus, but that it extended upon the insula over an indefinite area. Lepine[4] had already made the cautious suggestion that the various forms of aphasic manifestations arising from lesions in different portions of the lobe be carefully observed and studied, the surface of the insula being subdivided into smaller areas for this purpose. As late as 1885, Nothnagel was reluctant to decide for one or the other of the areas under discussion.

The location of these functions in the insula seemed further supported by the claim that this lobe exhibited the largest and most complex configuration in the human brain. E. C. Spitzka,[5] however, showed the fallacy of this argument in 1880, upon morphological grounds, since the porpoise possesses an even larger insula with nearly four times as many gyres as the average human brain exhibits. He made the tentative suggestion that the insular cortical field of the porpoise reached this high development because of the complex character of the innervations governing the muscles of the larynx and blow-hole of the cetaceans. It later occurred to the same author that the greater development of the caudal portion of the insula might find its explanation in the fact that "this is commensurate with the amplitude of the cortical field of the eight pair of cranial nerves, the functions transmitted by which—both equilibrium and audition—are highly developed in the cetacea."[6]



The upper figure represents the insula of *Tursiops Tursio*, or Bottle-nosed Dolphin. The lower figure represents a normal well-developed human insula. It is intended to show the remarkable contrast between the cetacean and the human insula. In the former the caudal (parieto-temporal) region is most redundant; in the latter it is the cephalic (frontal) region which is best developed. (Original drawings from specimens in the possession of the writer.)

The porpoise, while provided with clumsy flippers and a rudimentary dorsal fin, is capable of executing evolutions exceeding anything in the vertebrate domain, not excepting the blinded bats of Spallanzani, for they involve at once gross force and skill. The porpoise executes his remarkable evolutions around his own axis, while rushing along with the speed of a steamer. The auditory powers of this mammal are probably the most acute of which we know, for they can hear—it is said on good authority—the splash of nets falling into the water three miles distant.

The contrast afforded us by the study of the insula of the porpoise as compared with that of man is a most instructive and significant one. The insula of the porpoise, on the one hand, is narrow and pointed cephalad, while it is broad and well-developed caudad (see Fig. 1). On the other hand, the human insula shows the reversed condition. Putting these facts together, and in the light of Waldschmidt's observations discussed farther on, would it be rash to propose that the post-insula shares in its development that of the auditory sense centre, by virtue of association neurones with short axones, while the growth of the preinsula is more in consonance with that of the true "speech-centre" in the subfrontal operculum? After all, the development of the preinsula is only an intense expression of that feature by which the human brain excels all other animals, for in no lower form do we find the insula so fully developed in its cephalic region.

At the present time, largely because of the observations of Wernicke, Raymond, von Monakow, and Flechsig, the insula is generally regarded as a "mid

dle association centre," for few if any projection fibres are demonstrable, and beneath its cortex lie the association tracts connecting the auditory perceptive and the emissary centres.* Why the left hemicerebrum should be the seat of the co-ordinating principle of spoken language, as well as of the graphic representation of ideas in right-handed people, is a matter which has been fruitful of ingenious conjecture not immediately related to the present theme.

Before proceeding to the description of the insulæ in the brains of the eminent pair referred to, it may be well briefly to present the related observations of Waldschmidt and Donaldson. The subject of congenital mutism or deaf-mutism is intimately related to the clinical side of the speaking faculty, and important facts can be deduced from observations upon the brains of those defective in this particular.

Waldschmidt[7] describes the insulæ in the brains of two congenital deaf-mutes, and compares them with those of a normal dissecting-room subject, and of a laborer whose brain weighed 1,860 gm. He further describes those of the brains of two highly intellectual members of the faculty of the University of Freiburg, one a theologian, the other a prominent jurist. This author demonstrated that the left insulæ of both deaf-mute brains were of inferior development as compared with the right side, and that this atrophy was most marked in the region of the insular pole. So remarkable was this difference that had he not known the life-history of these persons he might have thought that he was dealing with left-handed individuals, having a right-sided speech-centre. Waldschmidt[8] ventures to say that this atrophy of the preinsular region may have some significant bearing upon the question of the associations of the speech-centre with the auditory sense-area in the temporal lobe.

Donaldson[9] observed upon the brain of Laura Bridgman that the "left insula is less well-developed than the right in every way except the length of the sulci, in which it is slightly superior," and in spite of the fact that on the whole the cortical area of the left hemi-cerebrum was greater. In addition both insulæ were exposed, the left more than the right. Donaldson estimated the exposed area to be 128 sq. mm. on the left, and 46 sq. mm. on the right side. He agrees with Rüdinger and others that this exposure is characteristic of incomplete development.

Waldschmidt's brains of the normal individual, and of the laborer, showed the reverse condition; the left insula being the better developed, the right insula being flatter and the preinsular pole less prominent. His most important discoveries were in the brains of the theologian and the jurist, for in these he noted that the left insula was preponderatingly developed as compared with the right side; not only in the increased development of the lobe as a whole, but especially of the preinsula.

So far as a search of the literature determines, writers generally agree that exposure of the insula indicates defective brain-development. Rolleston[10] in describing the brain of a male Australian adult, in which the left insula was exposed on account of defectively developed opercula, points out that this may have some relation with the primitive language of these savages. Mickle[11] says: "Defective in form are healthy human adult brains in the prime of life, with the island of Reil partly uncovered, thus showing impaired development. . . . When the uncovering, dealt with here, exists, it is the anterior portion of the insula which is most liable to be unroofed. . . . This partial uncovering of the insula is observed in some brains of low form; as, for example, in some idiots, imbeciles, and criminals; and, it has been said, in lower races of mankind." T. E. Clark[12] holds similar views as to the significance of insular exposure.

To show that this general view needs modification the writer offers the consideration of the following features.

In the brains of Dr. Edouard Seguin and his son Dr. Edward C. Seguin, the left preinsula is exposed. The brains under discussion are, however, far from being of low form or defective type. Indeed, their appearances are quite indicative of the high intellectual capacity of these two physicians. Nor are the opercular regions in the least defective; though they fail to come into typical apposition on the left side. The explanation of this anomaly is corroborative of Waldschmidt's findings upon the brains of the two professors, namely that the left preinsula is better developed than its fellow on the right side. So great is this development in the Seguin brains that in its struggle (if that term may be applied) to reach the general cerebral surface it has virtually thrust apart the opercular parts and made itself visible.

The evidence in favor of this hypertrophic development of the left preinsula is easily deduced from the soundings of the Sylvian cleft given in millimetres in the following table.

The terms "pre-, medi-, and post-insular depth" refer to the three points at which the sylvian cleft was sounded, the pre-insular point being the junction of the Sylvian with its presylvian ramus, the medi-insular point being at the middle of the course of the Sylvian, the post-insular being at the junction of the Sylvian with its episylvian ramus.

DEPTHS OF THE SYLVIAN FISSURE IN THE FOUR HEMICEREBRUMS OF THE TWO SEGUINS.

Edouard Seguin (father).

	Left.	Right.
Pre-insular depth	11 mm.	18 mm.
Medi- " "	22 "	22 "
Post- " "	24 "	22 "

Edward C. Seguin (son).

	Left.	Right.
Pre-insular depth	7 mm.	15 mm.
Medi- " "	20 "	23 "
Post- " "	25 "	25 "

The conclusions naturally to be drawn from the above are that the causes potential in insular exposure must be discriminated or classified as follows:

I. In the highly intellectual (for example, the two Seguins), owing to the excessive growth and development of the left preinsula causing a displacement of the opercula, thrusting them apart, as it were, and even though the latter be very well developed.

II. In the defective, exposure of the preinsula is due to deficient development of the opercula, and because these fail to approach each other. In such cases the insula itself is, without a single exception in the series studied by me, of inferior development, indicated not only by the soundings of the Sylvian cleft, but also by the flatness of configuration, and lesser area of the insular cortex.

A word or two in description of the Seguins' insulæ may not be amiss. Aside from the redundancy of the polar region of the left preinsula, these insulæ differ from those of ordinary brains in being marked by deeper fissures and by a complementary plumpness or fulness of the gyres. The left insula of the elder Seguin has four preinsular gyres (G. breves insulæ) and a postinsular gyrus (G. longus insulæ) which in its dorsal third is divided into two gyres by a short fissure. In this way are made up the six digitations into which all of these four insulæ divide. In the right insula of the father and in both insulæ of the son, we find five short insular gyres and a single long insular gyrus.

* "Centre des représentations verbales auditifs avec le centre des images motrices d'articulation." Raymond.[6]

It is possible that a similar exposure of the insula exists in the brain of another educated man, but as there are no detailed descriptions and measurements available, it is impossible at present to discuss the case. I refer to the brain of Chauncey Wright, a distinguished philosophical writer. The specimen is at present in the care of Prof. B. G. Wilder,[13] and is being described by him. Professor Wilder in a communication to me (January 9, 1910) calls attention to the fact that possibly pressure may have caused sufficient displacement during the process of hardening artificially to expose the insula. Dr. Dwight, who first prepared the specimen, does not recall the condition of the parts in the fresh state, and as Professor Wilder is at present at a great distance from his home, no conclusive statements can be made at this time. Upon the right side—Dr. Wilder writes—the insula is also exposed. The description of this half has not yet been published.

Sight must not be lost of a possible complicating factor. The deeper and the more numerous the anfractuosities of the insula, the more numerous and of greater calibre are likely to be the important branches of the medicerebral artery (A. fossæ Sylvii). That is, abundant ramification is found to accompany complicated insula development. Now as an abundant blood supply of the cortex in general is presumably a condition of higher potency of function, insular development *per se* is an expression of general development in this other respect as well as in the purely morphological one.

Among the reflections which occur in the course of such a study is the possibility of some paternal influence exerted on the brain of the offspring under circumstances such as the following: Dr. Edouard Seguin (the father) was most actively engaged in the teaching of the idiot children at the Hospice de Bicêtre, wrote many treatises, and delivered many lectures upon the subject, in the six years prior to the younger Seguin's birth. If physiological tendencies are transmitted from father to son, and if such transmission of function finds structural expression, one would expect it to be demonstrated when the circumstances are so favorable as here. Of course, all such statements are made tentatively; yet what would be a more natural conception, when we associate these circumstances with the visible evidences in the two brains, particularly corroborated by the soundings of the Sylvian fissure of both sides? Both men were of high intellectual capacity; both were facile writers and speakers—if anything, the son excelled the father; and both were polylinguists, speaking and writing three languages fluently. The teaching capacities of both men were remarkable, in the one case being especially devoted to the patient efforts required in training the feeble-minded, and in the other developed in the highest degree in didactic lecturing and clinical teaching. The pragmatical methodicity of the son has become traditional among his pupils and more intimate colleagues.

Jam, Marmalade, and Glucose.—Commenting on a recent legal decision in England in a case in which a manufacturer was accused of adulterating marmalade with thirteen per cent. of glucose, William Murrell has undertaken a series of observations to see whether the amount of glucose sold in the ordinary jams and similar preparations is injurious or not. He comes to the conclusion that its alleged injurious properties are greatly overestimated. In fact he says that he often orders commercial glucose as a food in two-drachm doses three times daily. He has never known it to disagree with the patient. He declares that it may be safely affirmed that there is no valid objection to the use of glucose as a substitute for cane sugar or beet sugar in jams or marmalade, and that prosecutions for employing it for this purpose are vexatious, and serve no useful purpose, but, on the contrary, are prejudicial both to the consumer and the maker, inasmuch as they tend to restrict the production of the best and most palatable form of an article of every-day consumption.—*Medical Press and Circular.*

Latest Investigations on Uric-Acid Diathesis.—Otto S. Binswanger holds that recent investigations prove that not uric acid but the alloxuric bases are the cause of the so-called uric-acid symptoms. Treatment consists, first, in limiting the nuclein ingestion, avoiding meat, internal organs, eggs, coffee, or tea. Secondly, the oxygen supply must be raised. Iron, out-door exercise, excursions to mountains or sea-coast will oxygenate the blood. The excretion of the alloxuric bases is favored by sodium salicylate, which, according to J. W. Goodbody, causes an increase in the quantity of urine excreted and in the specific gravity, and causes an increased breaking up of the proteids of the body. The hepatic cells are stimulated to increased formation of urea, and there is an increase in the quantity of "nitrogen rest" excreted. Crafton has "cut" attacks of gout and relieved migraine by oxygen inhalations.—*The Medical Examiner and Practitioner.*

The Process of Healing in Fractures.—Baldo Rossi instituted a series of experiments on rabbits, in order to ascertain the effect of massage and early movement on the healing of fractures. One set of animals was treated by daily massage and movements, a second with immobilizing apparatus, and a third left to nature. In the first set, the callus was found resistant on the third day (fifth day in the second set), and on the eighth day could be freed from all apparatus between the massage treatments, a result obtained on the twelfth to fourteenth day in the second set. Return of function came on the eighteenth day as against the thirtieth in the second set. As to the third set, the phenomena of recovery appeared a little later than in the animals treated by massage, and a little sooner than in those treated by immobilization. The results of microscopic researches bore out the clinical results.—*Archivio de Ortopedia*, Anno xvii., Nos. 5, 6, 1901.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM WOOD & CO., 51 Fifth Avenue

New York, June 15, 1901.

A PLEA FOR A MORE RATIONAL TREATMENT OF INSANITY.

IT is generally admitted that the treatment of the insane, in every civilized country, is conducted upon far more humane and intelligent principles than it was in by-gone times. Those afflicted with mental disorders are now cared for in the kindest possible manner. They are splendidly lodged, well fed, and plenty of amusement and healthful recreation are provided for their behoof. So far as it goes their treatment is beyond reproach. But unfortunately, and especially in the United States and Great Britain, the conception of the disease itself would appear to be somewhat limited. Or if this be not so, the theories, undoubtedly right, which have been formulated within the past few years with regard to the cause of the malady, have not been acted upon.

Dr. Ford Robertson, writing in the *National Review* for May, asks the question, "Is insanity incurable?" and answering in the negative goes on to make an eloquent appeal in favor of a treatment tending toward curative rather than custodial measures alone. He says in part: "Very many years have now passed since men of science began to raise their voices in protest against the fatal popular error that insanity is something quite different in its nature from other diseases. For long their teaching was scarcely heeded, for it rested upon inductions which, to the general public, were unintelligible, but it is capable of so clear a demonstration that almost any one can appreciate its truth. Within the past five or six years our knowledge of insanity has undergone what is nothing short of a revolution.

"It can now be shown that the various forms of insanity differ in their nature from other diseases in no respect except that of the particular tissues of which the functional activity is perverted or abolished. They are bodily diseases just as truly as typhoid fever, rheumatism, or a fractured leg, and they have similar causes."

This being so, the great motive of investigation in the field of the neurologist and alienist is the prevention and relief of insanity, and of other etiologically related diseases of the nervous system.

As remarked before, and as is well known, these views are by no means novel; they are held by the most noted authorities on mental and nervous affections in all parts of the world, and treatment in accordance with this teaching has been carried on in many countries of Europe for a considerable time. Psychopathic hospitals have been established in Vienna, Strassburg, Heidelberg, Leipsic, and in other European cities, the latest of these and probably the most complete and best equipped being that of Giessen.

There are no such institutions in this country, while in Great Britain the situation is yet worse, there being only one laboratory completely equipped and set apart for the prosecution of researches upon the pathology of insanity—namely, that established by the London county council in connection with the large insane asylum at Claybury.

That the two richest and not the least intellectual or generous countries of the world should thus lag in the movement for the benefit of suffering humanity, does not seem altogether in keeping with the natural order of things. Perhaps this backwardness may be put down to the curious lack of initiative in matters purely scientific, which would appear to have characterized the investigators of the United States and of Great Britain, especially the latter, for the past few years, though the serious handicap under which they labor—as compared with some foreign countries—in that the State has not stepped forward to give a helping hand, is a more plausible reason for this stagnation in laboratory research.

It is full time, however, that this stigma should be removed from both countries, and that their prominent men in all branches of science should be given every facility to occupy that place in the vanguard of nations to which their talents entitle them. The MEDICAL RECORD has urged on many occasions the need of isolating cases presenting mental and nervous symptoms until a careful investigation into their causes has been made. Such a course is indicated not only in order that a correct diagnosis may be rendered, thereby giving the patient a fair fighting chance of regaining health, but also that means may be afforded for clinical teaching. If students do not have the facilities to examine closely mental diseases, how then can they be expected to know and treat properly cases of this nature when met with in practice? Reception or psychopathic hospitals might be established in every large city on this continent with advantage to all concerned.

THE HOSPITALS OF JAPAN.

JAPAN has come to the front in so surprising a manner within the past few years, and moreover is destined to be still more prominent in the affairs of the Far East, that any facts regarding the country and its people are read by the American people, and especially since they have become directly interested in Asian politics, with more than ordinary attention. In addition to this the Japanese in themselves are a remarkable race. Although like their Chinese brethren imitative to a degree, they are besides endowed with a strain of originality, which appears to be totally lacking in the inhabitants of the Celestial Empire. The way in which the Japanese have assimilated European and American ideas, and to a lesser extent habits and customs, and

put to practical use their inventions, is certainly one of the most wonderful features of the present age. In no branch has this assimilative and progressive faculty been more clearly evidenced than in that of medical science. In original research at one bound its investigators have leaped into a very respectable position in the realm of science.

An illustration of Japanese enterprise is given by Dr. Edward C. Register, president of the board of medical examiners of North Carolina, and one of the editors of the Charlotte *Medical Journal*, in an account he has published of a visit paid to Japan last year, in which some of the principal hospitals of the country are described.

Japan, it appears, has but ten hospitals in the whole country, and taking into consideration that it has a population of forty-five millions, a fair proportion of whom live in cities, the largest of which is the size of Philadelphia, with three others each containing five hundred thousand inhabitants, this paucity of hospitals is somewhat a matter for surprise.

But although few in number, its public institutions for the care of the sick are for the most part models of their kind, and equal in almost all respects to the best in America and Europe.

The Imperial University Hospital of Tokyo, by far the most complete and important in Japan, is an immense establishment maintained nearly entirely by the government. It has eight resident physicians and six hundred trained nurses. The average number of in-patients is twenty-two hundred. The main building, which is plain and unpretentious, is situated in the midst of a beautiful park, artistically laid out. This building is used only for offices, reception rooms, parlors, library, museum, billiard rooms, drug rooms, and the microscopical department. The microscopical laboratory, probably the largest and most complete in the world, is under the charge of the celebrated Dr. Kitasato.

With the exception of the operating-rooms all the other buildings of this institution are one story high, made of wood, and join the rear of the large stone building, leading off from it at right angles, and parallel with each other. They are four in number and extend back possibly four hundred feet. About every hundred feet they are connected with each other by covered bridges with glass sides.

Immediately adjoining these buildings is one for the physicians, one for the nurses, and one for the servants, a department for lying-in patients, one for contagious diseases, and one for the insane.

The surgical department is a large two-story stone structure, containing several operating-rooms and amphitheatres, and can care for about two hundred surgical cases at a time.

The foregoing description will convey a sufficiently clear impression that the Imperial Hospital at Tokyo is as regards construction and external architectural features up to date, and exceedingly well adapted for hospital purposes.

Dr. Register, in touching upon the internal arrangements and equipment of the institution, was greatly struck by the small size and overcrowding of the wards. The rooms for single patients are very small, not over ten feet square, and furnished with velvet carpets, rugs, curtains, and cloth-covered sofas.

A characteristic of the methods of Japanese surgeons, which is noticed by those who have visited their hospitals, is their extreme conservatism. Patients are slow to consent to an operation. This seeming idiosyncrasy, however, may be doubtless attributed to religious prejudices. One of the most strictly observed tenets of the Buddhist faith is, never to cause bloodshed except when favored by the god of war.

This renders the surgical work rather unimportant when compared with other departments; nevertheless the aseptic arrangements are quite upon a level with those in vogue in the most modern hospitals, as is likewise the equipment generally.

The surgeons, though conservative, are not timid, but are skilful and successful operators.

A point that particularly attracted the attention of Dr. Register was the prevalence of tuberculosis in Japan. The records of the Imperial Hospital for a period of five years showed that thirty-five per cent. of all cases admitted were tuberculous. Rheumatism was the next most widespread disease observed, while skin affections were very rare. An explanation of the rifeness of consumption and rheumatism among the Japanese is that their houses and manner of life favor the propagation and development of these maladies, and the absence of skin diseases is due to their extreme cleanliness.

The Imperial Hospital is the medical centre of Japan, to which all the best people resort when they have to submit to an important surgical operation or are suffering from a serious disease.

Several other Japanese infirmaries are described by Dr. Register, none of which is equal in any respect to the large institution at Tokyo, but all show the exceeding aptness or rather genius of the Japanese to adopt and even to improve upon the most advanced methods of scientific treatment practised by nations in the van of civilization.

With regard to the capabilities and limitations of the Japanese physician, he is, in the opinion of Dr. Register, peculiarly well suited to work requiring excessive care and patience, as for instance microscopical investigations. In surgery, the smaller and more delicate and difficult the operation is the more it interests him. He is perfectly oblivious to the flight of time, and will give the most painstaking attention to small details which to the bustling, restless, and impatient American would appear unnecessary and tiresome.

As the prediction has been made frequently within the past few years that Japan will be the deciding factor in the balance of power in the Far East, the course of her evolution and development must perforce be followed with intense curiosity by all nations concerned in that portion of the globe. She is even now no longer the unknown quantity. The Land of the Rising Sun is fast becoming, if she has not already become, the Land of the Risen Sun, and her progress in medical and scientific matters is fully keeping pace with her phenomenal advance in all things that go to

make up the material prosperity of a nation. The comments of intelligent, skilled observers, such as Dr. Register, are therefore welcome and well timed.

SANATORIUM AND HOTEL IN CHICAGO.

A NOVEL experiment—but one which would seem to be at least worthy of a trial—is about to be entered upon by a few Chicago physicians. Five of the foremost physicians and surgeons of that city are preparing to build a large private hotel and sanatorium at a cost of $400,000. In Europe and in Great Britain many eminent surgeons have their private hospitals, in which difficult operations are performed and serious cases treated, the fact being recognized that better care can be given a patient in an establishment of this kind under the eye of the medical man himself, than in the most luxurious homes.

The plan proposed for Chicago, however, is conceived upon a wholly new principle, for, so far as we are aware, in no place either in this country or in Europe is a hospital run in connection with a hotel. Nevertheless such a scheme, if successfully carried out, will have its undoubted advantages. Physicians always have a number of patients who come from a distance, and who, unless the particular man under whose care they place themselves possesses a hospital of his own, have no choice but to go to a public institution, to a hotel, or to hire rooms. All these plans have their drawbacks. Many object to a general hospital; the noises and disturbances constantly occurring in a large hotel render it unsuitable for most cases of sickness, and in both hotels and apartments there is frequently much difficulty in securing accommodation for the relatives and friends of the sufferer.

A combination of hotel and sanatorium would obviate these inconveniences, and should afford a solution of the problem of how to treat patients of means to the satisfaction of themselves and their medical attendants.

The projected establishment at Chicago is to be provided with an ample staff of attending physicians as well as with a corps of nurses.

THE TEACHING OF ANÆSTHESIA.

IT will scarcely be denied that in a large number of operations—perhaps the majority—less is to be feared from the surgical procedure itself than from the anæsthetic. It would therefore seem obvious that no less consideration should be given in the medical curriculum to one of these than to the other. This is, however, not the case, and as a result the medical graduate is compelled to acquire, in hospital or in private practice, after leaving the halls of his alma mater, the necessary experience for successful anæsthesia. That this method is attended with serious dangers and that it may lead to disastrous results are all too obvious. To overcome this defect in medical education Dr. Dudley W. Buxton (*British Medical Journal,* April 27, 1901, p. 1005) recommends the attendance by the student, during the last year before the final examination, on six or even twelve lectures devoted to instruction in the theory of anæsthesia, its physiology, pharmacology, and practice, including familiarity with the common agents and mixtures and apparatus; and the administration of anæsthetics on twelve occasions as a minimum, together with watching anæsthetizations during such a period as would give fifty attendances including the twelve administrations.

News of the Week.

Yellow Fever in Havana.—The reports of Major Gorgas, the health officer of Havana, are becoming monotonous in their repeated showing of the almost complete absence of yellow fever in that one-time menace to the health of our Southern States. Only last week we reproduced in abstract the April report, wherein it was added that there had been only two cases during the month. That was favorable enough, but it was before the rainy season had set in, and a notable increase in the amount of the disease was to be looked for in May and subsequent summer months. But on June 1st there was not a single case known to the authorities, and on the 8th there was but one case. During the three months of March, April, and May there was only one death from the disease in Havana. yet the city was probably never so full of non-immunes as it is this year. The average mortality from yellow fever for those three months during the last thirteen years has been thirty-six.

Mrs. McKinley's Illness.—The physicians in attendance on the President's wife issued on Saturday last the following statement of the character of the illness from which she has been suffering: Mrs. McKinley's illness has been a blood infection, resulting from periostitis of the index finger, which began in Los Angeles, and which was promptly treated by incision. The subsequent condition of exhaustion was due to the same blood infection, associated with a severe diarrhœa. She improved, however, and was brought home in comfort and without loss of strength. The principal cause of anxiety in her case since her arrival in Washington has been an acute endocarditis, involving the mitral valve, the result of the same blood infection. This does not appear to be progressive, and there has been an improvement in the diarrhœa and in her general condition. Mrs. McKinley's case at the present time presents a more hopeful aspect.

A Big Charge for a Placebo.—It is stated in *The Medical Times and Hospital Gazette* (which, we are bound to say, publishes a good many steep stories of physicians in New York and elsewhere) that a Moscow doctor was not long since asked by a lady patient, who professed to be tired of life, for a drug that would cause her death painlessly. He prescribed a mild laxative, but before handing it over he induced his patient to give him all her available money and jewels, valued at 2,000 roubles. He anticipated that when the lady did not die she would be too shamefaced to explain the matter to the police, but in this he was

wrong, for the lady no sooner found that she had been deceived than she denounced the doctor as a fraud. He was promptly arrested, and in spite of his defence that at the time of the offence he was hopelessly under the influence of drink, the court found him guilty, sentencing him to six months' imprisonment, with loss of all civil rights, including the right to practise his profession.

The Cleveland "Medical Gazette."—The current issue of this journal is replete with good things. It contains no less than fifteen interesting items scissored from the columns of the MEDICAL RECORD without a word indicating their source. This is worse than the organ of the Chicago Medical Society—an old and hardened offender.

Rewards for the Conviction of Medical Offenders.—The Massachusetts Society for the Prevention of Cruelty to Animals offers what its president calls a "prize" of $100 for evidence enabling the society to convict any man in Massachusetts of cruelty in the practice of vivisection, and another "prize" of $25 for evidence to convict of violating the recently enacted law of Massachusetts against vivisections and dissections in the public schools.

A Sanatorium for Consumptives in Hartford.—The directors of the Hartford Hospital have issued an appeal for $40,000, with which to build a sanatorium for the treatment of tuberculosis. The location selected is on Cedar Mountain, three miles southwest of the city. It is proposed to erect a building which will accommodate fifty patients and the necessary attendants. There are to be two large open-air wards, with glass roofs and ends, facing south. Here the patients will spend the days, receiving the benefit of both air and sun.— *Yale Medical Journal.*

The Illinois State Medical Society.—The fifty-first annual meeting of this society was held at Peoria, on May 21st, 22d, and 23d, under the presidency of Dr. George N. Kreider, of Springfield. The following were elected officers for the ensuing year: *President*, Dr. John T. McAnally, of Carbondale; *First Vice-President*, Dr. M. L. Harris, of Chicago; *Second Vice-President*, Dr. J. W. Hensley, of Peoria; *Permanent Secretary*, Dr. Edmund W. Weis, of Ottawa; *Assistant Secretary*, Dr. Charles D. Center, of Quincy; *Treasurer*, Dr. Everett J. Brown, of Decatur; *Editor*, Dr. George N. Kreider, of Springfield. The next annual meeting will be held at Quincy, on May 20, 21, and 22, 1902.

Complaint against the New York City Health Department.—Certain residents of Woodside, in Queen's County, have brought charges of neglect against the health officials of their borough, and the grand jury has been instructed to investigate the complaint, which is based upon the death of a man from black smallpox on May 4th. The complaint sets forth that, although suffering from a malignant form of the disease, the man was allowed to remain in a big tenement house. He died in the afternoon of May 4th, and it is charged that his body was allowed to lie without attention for a space of fifty-two hours; that it was then placed in a common pine box and carted through the streets; that the man's family was driven from its home after his death; that, in view of this action, proper precautions were not used; and that the family was not isolated, although in direct contact with the sick man.

Pasteur Institutes in the South.—A Pasteur Institute has recently been established by the University College of Medicine in Richmond, Va., and another, upon the recommendation of the Georgia State Medical Association, at Atlanta, Ga.

Board of Health an Undesirable Neighbor.—The Jersey City health board has been requested to remove its offices from the city hall, the frequent appearance at the board's rooms of smallpox patients having made the other city officials nervous. A building in Mercer Street was hired, but a resident of the adjoining house became alarmed and has paid the owner $600 on condition that the health department find other quarters.

An Army Hospital Burned.—Fire occurred in the general army hospital at the Presidio, San Francisco, on Monday. The entire building was threatened with destruction, but owing to a lucky change in the direction of the wind the greater part was saved, the damage being confined to the north end of the building, where were the kitchen and dining-rooms. One ward was burned out and another was badly damaged. All of the patients, many of them suffering from measles, were safely removed from the building. The hospital was built in 1899.

The Missouri State Medical Association.—At the recent annual meeting of this society at Jefferson City, the following officers were elected for the ensuing year: *President*, Dr. J. D. Griffith, of Kansas City; *First Vice-President*, Dr. R. E. Young, of Jefferson City; *Second Vice-President*, Dr. J. C. Whaley, of Osceola; *Third Vice-President*, Dr. R. M. Funkhouser, of St. Louis; *Fourth Vice-President*, Dr. J. F. Campbell, of Callao; *Fifth Vice-President*, Dr. G. W. Vineyard, of Jackson; *Recording Secretary*, Dr. B. C. Hyde, of Kansas City; *Assistant Recording Secretary*, Dr. F. W. Burke, of Sedalia; *Corresponding Secretary*, Dr. Charles W. Fassett, of St. Joseph; *Treasurer*, Dr. J. Franklin Welsh, of Salisbury. The next meeting will be held in St. Joseph.

Tuberculosis a Bar to Immigration.—On the strength of a declaration by the surgeon-general of the Marine-Hospital service that pulmonary tuberculosis is a dangerous contagious disease, the superintendent of immigration has issued an order that in future immigrants with tuberculosis of the lungs must be debarred from all ports of the United States regardless of boards of special inquiry, which heretofore have used their discretion in the matter. Formerly the board of special inquiry at this post, after receiving the report on a case of tuberculosis from the chief of the medical division of the immigration service at New York, could exercise discretion as to the admission of the person, and there have been instances in which a child ill of the disease has been permitted to

land with its parents; but henceforth no one with consumption will be admitted to the country. The rule will apply also to alien passengers in the first and second cabins as well as to those in the steerage.

The Mississippi State Medical Association.—The thirty-fourth annual meeting of this society was held at Jackson, on May 8th, under the presidency of Dr. H. A. Minor. The election of officers resulted in the following choice: *President*, Dr. J. M. Buchanan, of Meridian; *First Vice-President*, Dr. C. D. Mitchell, of Pontotoc; *Second Vice-President*, Dr. Anthony Miller, of Panther Burn; *Recording Secretary*, Dr. C. H. Trotter, of Winona; *Assistant Secretary*, Dr. B. L. Culley, of Jackson; *Corresponding Secretary*, Dr. D. S. Humphreys, of Greenwood; *Treasurer*, Dr. J. F. Hunter, of Jackson. The next meeting will be held at Jackson on April 16, 1902.

The Connecticut Medical Society.—The one hundred and ninth annual meeting of this society was held in Hartford, May 22d and 23d, under the presidency of Dr. Leonard B. Almy, of Norwich. The following were elected officers for the ensuing year: *President*, Dr. John H. Granniss, of Saybrook; *Vice-President*, Dr. J. A. Shelton, of Shelton; *Secretary*, Dr. N. E. Wordin, of Bridgeport; *Assistant Secretary*, Dr. J. H. Townsend, of New Haven; *Treasurer*, Dr. W. W. Knight, of Hartford; *Committee on Matters of Professional Interest*, Drs. N. R. Hotchkiss, of New Haven, E. K. Root, of Hartford, and E. P. Flint, of Rockville.

Women Graduates of Cornell.—At the commencement exercises of Cornell University Medical School on June 5th, twenty-six graduates received their diplomas. Fourteen of the graduates were women. One of them, Emily Dunning, took the second prize of $100 for the best work in the four years' course. Miss Dunning had already received the degree of master of arts from Cornell. She is reported in the papers to have beaten all candidates in a competitive examination for internes at Mount Sinai Hospital, but failed of appointment because of her sex. The first prize of $150 was awarded to Mark S. Fleming and the third of $50 to Edward Francis Kilbane. The prize given for the best work in otology, a set of instruments, was awarded to Ethel Mayer. The address to the graduating class was delivered by Gen. Stewart L. Woodford.

Special Insurance for Total Abstainers.—In answer to a numerously signed petition, the Equitable Life Insurance Society of this city has agreed to put in a special class any successful applicant for insurance who declares that he has been a total abstainer from the use as a beverage of alcoholic liquors, including wine, beer, and fermented cider, and as a condition of membership in this class agrees to remain a total abstainer as long as his policy is in force. Any surplus apportioned to the policy will be based on the experience of the society on policies belonging to the total-abstinence class. It is believed by the petitioners that the number of the total-abstinence class will receive the benefit of largely increased dividends. A number of British life insurance companies have for many years segregated their total-abstinent policy holders.

Medico-Chirurgical Association of Mississippi is the name of a society organized by fifteen colored physicians at Jackson, Miss., on May 17th.

The Ollier Monument Subscriptions.—The American committee for the erection of a monument to the late Professor Ollier, of Lyons, France, announces the receipt of $649 from one hundred and three subscribers.

Medical Society of New Jersey.—The annual meeting of this society will be held on June 25th, 26th, and 27th, under the presidency of Dr. William Pierson, of Orange, at the Hathaway Inn, Deal Beach, and not at Allenhurst as was at first intended. The secretary of the society is Dr. William J. Chandler, of South Orange.

Supposed Smallpox in Suffern.—Several cases of "Cuban itch" have been reported to the State department of health by a physician of Suffern. It is suspected that an epidemic of smallpox is being hidden under the term "Cuban itch," and an officer of the department has been sent to Suffern to investigate.

A Photographer Violates the Health Laws.—A photographer in Plainfield, N. J., was recently fined $50 for taking the picture of a child who had died of diphtheria. The charge was that he had broken a health-board ordinance in going to the house where there had been such a disease. He explained that he had taken the portrait at the request of the child's father, and declared that he had not been informed of the nature of the disease from which the child had died.

Storage Charges on a Leg.—Several years ago a wealthy resident of Concord, N. H., lost a leg, which he had preserved in alcohol and stored in a drug store. When he died, twelve years later, the leg was taken from its jar and interred with his body. Shortly after the druggist who had cared for the leg sent to the trustees of the estate a bill for $3,450 for services rendered in connection with the amputated limb. This bill the trustees refused to pay, and the druggist brought suit. The case was tried in the superior court, and a jury brought in a verdict for the plaintiff for $1,979.16.

Taxing Charitable Institutions.—It is stated in *Charities* that the question of the assessment of the Hartford Retreat for the Insane is now being considered in Connecticut. This institution, it appears, has heretofore been exempt from taxation, on the ground of its being a charitable institution. In opposition, it is charged that the institution is maintained for profit, and therefore should be taxed on a commercial basis. This is a question of very wide interest and applies to a number of institutions in this country, such as Bloomingdale Asylum in New York, the McLean Hospital at Waverley, and the Pennsylvania Hospital at Philadelphia, all of which enter into competition with the Hartford Retreat. In opposition, it

is maintained that these institutions all contribute to the care of the indigent by endowments for free beds, and, as a matter of fact, expend all the income in maintaining the institution. It seems there should be a distinction between hospitals making a profit and declaring a dividend, and those which spend their entire income in maintenance.

Dr. Joseph C. Beck has been elected pathologist and professor of otology at the Chicago Eye, Ear, Nose, and Throat College.

A Queer Verdict.—A despatch from St. Louis to *The New York Times* says that the head of a man, wrapped in an old coat, was found recently in East St. Louis, and when the coroner held an inquest over it a verdict of suicide was returned.

Free Rides for Bellevue Physicians.—During the trial of a suit for damages against the Metropolitan Street Railway Company recently, two former internes at Bellevue testified that all the members of the house staff of the hospital received books of passes on the lines of the company.

Opposition to a Hospital.—Residents and property-holders of Narbeth, a suburb of Philadelphia, have organized in protest against the erection of a pay hospital for contagious diseases within its limits, and an ordinance has been passed by the borough council forbidding the erection of any such hospital within one thousand feet of any street, residence, or building operation.

Leprosy in France.—Dr. Besnier recently presented a report to the Paris Academy of Medicine regarding the increase of leprosy in France. The report stated that the disease was becoming so prevalent in various parts of the country that stringent measures were urgently needed for its suppression. In Savoy and Brittany there were several distinct endemic centres, and at the Hospital St. Louis, in Paris, fourteen lepers were at present under treatment.

A Physician's Claim for $100,000.—Dr. Emma N. Warne, a woman physician of Chicago, has filed a claim for $100,000 against the estate of a Mr. Wheeler who died a year ago, leaving $3,000,000. The claim is based on a special contract for medical services and personal attention paid to Mr. Wheeler, the terms of the contract reading that Dr. Warne was to "take care of Mr. Wheeler as long as he lived." The physician's services are said to have extended over several years.

A Rival Claimant for a Yellow-Fever Serum.—Mr. A. Fontana Xavier, consul-general of Brazil in this city, has written to *The Sun* to say that a letter published in a New York newspaper recently from Dr. Angelo Bellinzaghi, now in Brazil, gives the erroneous impression that he and not Dr. Philippe Caldas is the discoverer of the yellow-fever serum. Señor Xavier says that it is true that Dr. Bellinzaghi was in Mexico making experiments with this serum, but that he was sent there as a paid assistant of Dr. Caldas, who, he declares, is its recognized discoverer. Last January, when Dr. Bellinzaghi was in this city, an effort was made to form a company for the manufacture and sale of his alleged specific. The intention was to charge $25 or $50 for giving the prophylactic injections to any one going to or resident in a yellow-fever district. Whether immunity would be assured under a pecuniary penalty had not been decided at the time the project fell through from lack of capitalistic faith.

Enlargement of St. Mary's Hospital.—Plans have been filed for the addition to St. Mary's Hospital for Children of a one-story brick building, twenty-five by forty-two feet, on West Thirty-fifth Street in the rear of the main structure.

The Medical Society of the State of West Virginia.—At the annual meeting of this society, held at Grafton on May 22d, 23d, and 24th, Dr. G. A. Aschman, of Wheeling, was elected president, and Dr. William G. Golden, of Elkins, secretary. The next meeting will be held at Parkersburg in May, 1902.

Vivisection in England.—A parliamentary report recently issued shows that during the year 1900, 247 licenses were issued for vivisection, but of this number 63 licensees performed no experiments. The total number of experiments was 10,839, an increase of 2,370 over the number for 1899. This increase is explained in part by the inoculations of bubonic plague made for diagnostic purposes.

The Roentgen Society of the United States.—The second annual meeting of this society will be held at Buffalo on September 10 and 11, 1901, in the University building. A copy of each paper to be read at this meeting must be in the hands of the secretary, Dr. J. Rudis-Jicinsky, of Cedar Rapids, Ia., on or before August 20th. The president of the society is Dr. Heber Robarts, of St. Louis, Mo.

The Collection of Tuberculosis Statistics.—The State department of health is about to take an enumeration of the people in this State afflicted with tuberculosis. The present purpose is not to obtain a personal registry of these cases, nor to institute a system of sanitary inspection or isolation of consumptives, but to obtain with such accuracy as is possible a record of the number of persons in each municipality who at this time are subjects of this disease; to learn the locality of the disease, its distribution, and surroundings. This accumulation of data will be fundamental to more exact plans for its control. It will likewise be of value in the discussion of the question of State care of consumptives. There are about thirteen thousand deaths from tuberculosis annually in this State.

Hospital Corps Instruction in Manila.—On Wednesday, March 27th, the graduating exercises of the third class of the Hospital Corps Company of Instruction were held at Hospital Number Three, Manila. There were nineteen graduates in a class of fifty-one, and of these three were honor men: For best general average, Clarence C. Yelton; for the best drilled man, Bernard L. Davenport; for the best examination in nursing, William T. Lambert. Addresses were made

by Lieutenant Lyster, commander of the class; Colonel Greenleaf, chief surgeon of the division, and General MacArthur. An exhibition was given of practical field work by the members of the class. The commanding officers, Major Kulp and Lieutenant Lyster, were warmly congratulated by the speakers upon the effective work which they had accomplished in organizing and perfecting the fourteen weeks' course of instruction for hospital corps in Manila.

Smallpox in Cleveland.—A report from Toledo, O., states that there was recently a secret meeting of the health authorities of five of the chief cities on the lakes, generally understood to be Toledo, Chicago, Toronto, Buffalo, and Detroit, at Cleveland, when a demand for better smallpox sanitation in Cleveland was made. Cleveland has had this year nearly one thousand cases, and is likely to have many more, as her wonderful mayor has entered the flock of anti-vaccinationists, and has been delivering himself of the usual protests against introducing poisonous material into the human body. It is suggested that the lake cities establish a quarantine against Cleveland.

The British Congress on Tuberculosis.—This congress, which has for its aim the prevention of consumption and other forms of tuberculosis, is to be held in the Queen's Hall, London, from July 22d to July 26th. The president is not yet appointed, but among those holding office are Sir William Broadbent, Professor T. Clifford Allbutt, Sir James Crichton Browne, Sir James Blyth, the Earl of Derby, and Lord Avebury. The sections are four in number: A state and municipal section, of which the president is Sir Herbert Maxwell; a medical section, president Sir R. Douglas Powell; a pathological and bacteriological section, president Professor G. Sims Woodhead; and a veterinary section, president Sir George Brown. The state and municipal section will be divided as follows: In Division I. will be considered statistical matters; in Division II., the notification of tuberculosis; in Division III., the influence of housing and aggregation (these two divisions will be taken together); in Division IV., the control of milk and meat supplies; and in Division V., the provision of sanatoria. Two distinguished foreigners are expected to take part in this section, namely, M. Henri Monod and Dr. A. J. Martin. In the medical section a discussion will be opened upon "Climatology," by Dr. C. Theodore Williams and Dr. J. Burney Yeo. On July 24th there will be a discussion upon the "Therapeutic and Diagnostic Value of Tuberculin in Human Tuberculosis," to be opened by Dr. Heron, in conjunction with the Pathological Section. On July 25th a discussion will be opened by Professor Allbutt upon "Sanatoria for Consumption." Demonstrations are announced upon cases of skin tuberculosis and their treatment, and of the use of Roentgen rays in diagnosis. The discussion in the pathological section will be as follows: On July 23d, "The Morphological and Physiological Variations of the Bacillus Tuberculosis and its Relations (*a*) to Other 'Acid-Fast' Bacilli, and (*b*) to the Ray Fungus and Other Streptothrices"; to be opened by Alfred Moeller, dirig. Arzt der Heilstätte Belzig, bei Berlin, and Dr. William Bullock, bacteriologist and lecturer on bacteriology and pathology to the London Hospital. On July 24th, "The Tissue Changes and Constitutional Effects Produced by the Various Constituents of Tuberculin." This will be a joint discussion in common with the medical section, to be opened by Professor Koch. On July 25th, "The Varieties of Tuberculosis (Morbid Anatomy and Histology)," to be opened by Professor Benda, Urban-Krankenhaus, Berlin, Professor Sheridan Delépine, professor of pathology Victoria University (Owen's College), Manchester, and Professor D. J. Hamilton, professor of pathology, University of Aberdeen. July 26th, "Mixed Infections in Tuberculosis." Among others who are expected to take part in this section are Dr. Roux and Professor Metchnikoff, of the Pasteur Institute, Paris. In addition to the work of the sections described above, the following public addresses will be given to the whole congress: On Tuesday afternoon (23d), by Professor Koch, Berlin; on Wednesday afternoon, by Professor Brouardel, of Paris; and on Thursday afternoon, by Professor McFadyean, of the Royal Veterinary College. The official languages at the congress will be French, English, and German. The honorary secretary-general is Mr. Malcolm Morris, 20 Hanover Square, London.

Philadelphia Hospital.—By a recent ruling of the Department of Charities and Correction, of the twenty-four resident physicians for the Philadelphia Hospital, elected annually after civil-service competitive examination, seven shall be graduates of the University of Pennsylvania, seven of Jefferson Medical College, seven of the Medico-Chirurgical College, and three of the Woman's Medical College. The application of such a rule would be, to say the least, unfortunate. In the first place, it destroys any value that may reside in competitive examination, and it opens dangerous opportunities for favoritism and pernicious political activity, and for this reason it will help to deter the better class of graduates from applying for the positions. In the next place, it will exclude from the competition all but graduates of local schools. This may be civic loyalty, but it is extremely provincial and narrow, and can only work harm. What provision would be made should there be fewer applicants from any school than those allotted to it can only be surmised. It is to be feared that the places might not go to the best equipped graduates, but rather to those with the greatest political influence. There can be only one fair apportionment of hospital positions, and that is to award them to those who exhibit the highest qualifications, irrespective of politics or college of graduation.

The Kentucky State Medical Society.—The annual meeting of this society was held in Louisville on May 22, 23, and 24, 1901, under the presidency of Dr. James H. Letcher, of Henderson. The election of officers resulted in the choice of the following: *President*, Dr. T. B. Greenley, of Meadow Lawn; *First Vice-President*, Dr. George M. Raddish, of Somerset; *Second Vice-President*, Dr. B. L. Coleman, of Lexing-

ton; *Secretary-Treasurer*, Dr. J. Steele Bailey, of Stanford, re-elected; *Librarian*, Dr. Frank Lapsey, of Paris. Paducah was chosen as the place of meeting for the third week of May, 1902. Dr. Frank Boyd, of that city, was appointed chairman of the committee of arrangements. The president-elect, Dr. Greenley, is the oldest member of the society.

A Case of Suspected Plague near London.—At Willesden, a suburb of London, a man supposed to be suffering from a mild attack of bubonic plague has been discovered. Persons with whom he had come in contact were detained, but have now been released. The patient himself is under observation.

Dr. Loir of the Pasteur Institute Shot.—A man entered the laboratory of the Pasteur Institute in Paris one day last week and fired four shots from a revolver into the body of Dr. Loir, a nephew of Pasteur. The bullets were extracted, and it is hoped the wounded physician will recover. The would-be assassin was arrested.

The Presidency of Johns Hopkins University.—Professor Ira Remsen has been elected president of the Johns Hopkins to succeed Dr. Daniel C. Gilman, who resigned recently. Professor Remsen was born in this city in 1846. He was graduated from the College of the City of New York in 1865, and later received the degree of M.D. from the College of Physicians and Surgeons, that of Ph.D. from the University of Göttingen, and LL.D. from Columbia and Princeton. From 1872 to 1876 he was professor of chemistry at Williams College, and then was called to the same chair at the Johns Hopkins.

A Congress of Life-Insurance Examiners.—The second international congress of medical officers of life assurance companies will be held in September next at Amsterdam. This meeting promises to be one of great interest, if one may judge by the list of titles published in the preliminary programme. We regret that the programme contains the names of no Americans. The congress will consider and if possible formulate the conditions on which it might be practicable to extend assurance to invalids and under-average lives. Each member will receive a copy of the transactions of the congress. The membership fee is fixed at ten guilders, equivalent to about four dollars.

Medical Students in Paris.—At the end of the academic year 1899–1900 the number of medical students in the Paris faculty was 4,315. At the opening of the present academic year on October 1st it was 4,166, a decrease of 149. This decrease is attributed to the new programme of studies and to the regulations as regards foreigners obtaining the State diploma. Up to the present foreigners have shown but little alacrity in endeavoring to obtain the university degree, which does not give the right to practise. It is noted, however, that sixty foreigners have obtained either complete exemption or equivalence of university titles required for inscription in the Faculty of Medicine. It is pointed out in the report presented to the University Council that this number is too large, and the responsibility for the excess of favor shown in such cases is laid on the minister of public instruction, who is said to yield too readily to the solicitations of foreign embassies instead of taking his stand solely on the university regulations. Of the 60 practitioners referred to, 14 are Russians, 9 subjects of the Ottoman Empire, 7 Roumanians, and 5 Greeks. The remaining 25 consist of single individuals of diverse nationalities. In the academic year 1899–1900 the faculty conferred the degree of doctor on 658 candidates. Of these, 572 were French, 7 of them being women, and 86 foreigners—59 men and 27 women.—*British Medical Journal.*

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy, for the week ended June 8, 1901. June 1st.—Doctors J. W. Backus, F. A. Asserson, J. F. Murphy, W. Seaman, and R. R. Richardson appointed assistant surgeons in the navy. June 4th.—Surgeon F. J. B. Corderio detached from the *Buffalo*, June 10th, and ordered home to wait orders. Surgeon L. W. Curtis ordered to the *Buffalo*, June 10th. Passed Assistant Surgeon E. S. Bogert, Jr., commissioned surgeon from December 15, 1900. June 6th.—Assistant Surgeon R. W. Plummer detached from the *Nashville* and ordered to the *Princeton*. Assistant Surgeon W. Seaman ordered to the *Independence* June 17th. Assistant Surgeon H. H. Haas detached from naval hospital, New York, June 10th, and ordered to the Norfolk navy yard. Assistant Surgeon R. R. Richardson ordered to naval hospital, New York, June 10th. Assistant Surgeon J. M. Brister detached from the *Independence*, June 17th, and ordered to the Asiatic station via transport *Hancock*.

Workmen's Insurance in Germany.—The system of workmen's insurance in Germany is a huge piece of state machinery. The magnitude of the system may be estimated by the fact that it pays out, in one way or another, about 1,000,000 marks ($250,000) a day. The sick workman has no longer to trouble himself as to how he shall obtain money to pay for medical treatment, and what will become of his family should he himself be rendered unfit for work. The workman whose earning power is reduced by an accident connected with his employment now obtains just compensation; and the aged poor have the satisfaction of knowing that, although they can no longer work, they can still, owing to the insurance system, contribute their share toward the expenses of the household, and are not obliged to depend on the earnings of their children or on ordinary public charity. The system of workmen's insurance has been gradually built up within the last seventeen years, but it is admitted that improvements are required and gaps have still to be filled in.—*British Medical Journal.*

Obituary Notes.—Dr. Seth B. Sprague died at his home in Jersey City, on the morning of June 5th. He was born at Dexter, Me., on January 12, 1840, and was graduated from the Medical School of Maine (Bowdoin College) in 1867. He practised medicine at Milo, Me., for twenty-four years before moving to

Jersey City. Dr. Sprague is survived by his wife and five children, one of whom, Dr. Ezra K. Sprague, is a passed assistant surgeon in the Marine-Hospital service.

Major Louis S. Tesson, surgeon U. S. A., died at Vancouver Barracks, Washington, on June 7th.

Dr. Maurice Lauren Healy, of 220 East Thirty-sixth street, this city, died at the home of his mother in Plattsburg, N. Y., on June 5th, of pneumonia. Dr. Healy was born in Plattsburg thirty-seven years ago. and was graduated from the New York University Medical College in the class of 1887. For three years he was a lecturer of the Post-Graduate College, and was assistant in Demilt Dispensary.

Obituary.

WILLIAM HUDSON DALY, M.D.,

PITTSBURG, PA.

Dr. William Hudson Daly, of Pittsburg, killed himself on June 9th by a pistol bullet in the head. He was born near Blairsville, Indiana County, Pa., on July 11, 1842. He studied for a time at the Jefferson Medical College, and in 1864 entered the United States army as a medical cadet, serving in various hospitals until the end of the Civil War. He then went to Ann Arbor and was graduated from the medical department of the University of Michigan in 1866. He went immediately to Pittsburg, where he practised up to the time of his death. He early turned his attention to laryngology, which he practised as a specialty, but was interested in many other branches of medical science. At one time he engaged in an animated discussion in the columns of the Medical Record and elsewhere on the etiology of malaria, being a firm believer in the water-borne theory of the disease. This was before the discovery of the mosquito's agency in the development and transmission of the plasmodium. During the Spanish war Dr. Daly was a surgeon of volunteers on General Miles' staff. It was he who started the "embalmed beef" controversy, the question being raised in a report which he made to General Miles. He said his attention was first called to the matter by seeing a quarter of beef hanging exposed to the sun at Tampa. He marvelled at this, and cut off a piece of the meat, boiled it, tasted it, and was sick for several days thereafter. The report was the one upon which General Miles relied mainly to substantiate his charges that the meat was not fit for consumption. Dr. Daly was an ex-president of the American Laryngological Association, of the American Laryngological, Rhinological, and Otological Society, and of the Section of Laryngology of the Ninth International Medical Congress. He was a member of the American Climatological Society, the Mississippi Valley Medical Association, the Association of Military Surgeons of the United States, the American Medical Association, the Medical Society of the State of Pennsylvania, of the Tri-State Medical Society, and of the Allegheny County Medical Society, and was an honorary or corresponding member of many European laryngological societies. Dr. Daly was a man of large physique, great vital energy, and a strong personality, and when engaged in any controversy was what is called "a good fighter," and it was mainly owing to his insistence that the beef question grew almost to the proportions of an army scandal. Dr. Daly lost his wife, whom he had married in 1869, two years ago.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 6, 1901.

Idiopathic Abscess of the Kidney.—A. J. Cabot mentions several sources of kidney abscess, dwelling especially upon infection through the blood. The streptococcus, the staphylococcus pyogenes aureus, the bacterium coli commune, the pneumococcus, and the typhoid bacillus, all circulate through the blood, and are probably eliminated in some degree by the kidneys, causing a so-called terminal infection, in which little capillary tufts are plugged by emboli containing the micro-organisms. It sometimes happens that an abscess occurs in but one kidney, and no source of infection is found; these abscesses used to be regarded as idiopathic, but the writer considers that small points of infection in the intestinal mucous membrane or elsewhere may have been overlooked. A case is reported in which the infection was due to a pure culture of colon bacillus. In cases of doubt, exploration by incision is justifiable. Should there be no abscess, but a tense, congested kidney, incision of the capsule along the convexity will usually afford great relief.

The Effects of Training.—Eugene A. Darling studied a number of students under training for football, rowing, etc. A considerable degree of cardiac hypertrophy was found, while the immediate effect of a severe effort like a race is an acute dilatation, which, however, is merely temporary, and becomes less marked with each succeeding effort if the man is in good condition. The hypertrophy is more or less permanent, but is not to be considered an undesirable thing, any more than a corresponding hypertrophy of the biceps. Albumin, casts, and red blood corpuscles were found to considerable amount in the urine passed immediately after hard playing; during training, in six cases out of sixteen albumin was present in small amount. No ill effects, which could reasonably be attributed to training, were to be discovered nine months after stopping the training.

Philadelphia Medical Journal, June 8, 1901.

The Knee Jerks in Chorea.—Augustus A. Eshner states that the two conditions most likely to be mistaken for chorea are spasmodic tic and the athetoid movements attending various cerebral lesions. The knee jerks are unchanged in cases of spasmodic tic and exaggerated in those of athetosis, while in cases of chorea they are extremely variable in different cases and even in the same case at different times, being sometimes increased and sometimes enfeebled or wholly wanting. Gordon has called attention to a peculiar modification of the knee jerk, which he believes to be common in cases of chorea. This does not seem to be constant, but when present is considered distinctive. The writer is able in part to verify Gordon's statements concerning this subject. With the patient recumbent and the knee raised, while the heel rests on the couch and the muscles of the extremities are relaxed, if the patellar tendon be struck the foot rises, but instead of falling back immediately, it remains suspended for a variable time, then sinking back slowly to its original position. Sometimes, it is said, there is merely a sluggish descent following an ordinary ascent. Sometimes there is the ordinary knee jerk, but as the foot is beginning to descend it is caught in mid-air and held for a time, or is even raised to a higher level than was reached in the first jerk. Sometimes the knee jerk passes at once into active, more or less persistent—even apparently voluntary—rigid extension of the extremity. This phenomenon is said to be best seen in mild cases, and in hemichorea only on the affected side. It is thought that the manifestations noted are due to an additional involuntary movement evoked by the knee jerk.

Heredity as a Factor in Mental Deficiency.—T. Alexander McNicholl declares that heredity prepares the soil and implants the tendencies; environment may modify them. If in one or in successive generations the system is devitalized, the result will be mental deficiency, loss of organic integrity, dipsomania, epilepsy, or other psychoses. Observation of 10,000 children show 8.8 per cent. to be more or less mentally deficient. The dulness of 40 is reported as due to environment and physical conditions such as poverty, defective sight, deafness, and general constitutional weakness; in 221 it is supposed to be due to heredity; 471 were children of drinking parents; of the remainder no definite information was obtained. Those conditions which impair the integrity of nerve tissues or profoundly affect nutrition are the active agents in the preparation for the transmission of hereditary ills. A most notable fact in the families of the children whose family histories were traced was the constant relation of alcoholism in the ancestry to abnormal physical conditions in the descendants. While eighty-seven per cent. of these children of

drinking and neurotic ancestry were mentally deficient, seventy-six per cent. suffered from some neurosis or organic disease. Of the children of abstaining households who were studied, less than three per cent. were dull, and but eighteen per cent. suffered from any neurosis or organic disease.

British Medical Journal, June 1, 1901.

The Position in which the Regurgitant Aortic Murmur is Most Clearly Audible at the Base of the Heart.—H. W. Syers calls attention to the fact that at least ninety-five per cent. of the cases in which aortic reflux occurs, the diastolic murmur is heard much more loudly at the second left interspace close to the sternum than in the position usually assigned to it—the second right interspace. The writer affirms, not that the second left interspace close to the sternum is the place where the aortic reflux murmur is most loudly heard, but only that it is much more distinct there than in the position ordinarily assigned to it. The point at which the murmur is loudest is almost invariably the middle of the sternum, and it is often loudly audible just above the xiphoid cartilage. The ordinary loud sound of a double aortic murmur is audible without the least difficulty, but the writer is referring to that low-pitched, soft, aortic murmur which often accompanies but does not replace the second sound, and which is of evil significance. Again, the writer states that he has just examined a case in which the reflux murmur was more loudly audible over the right than the left second interspace—an exception which proves the rule. The writer believes that aortic regurgitant disease, except in its unmistakable form, is the most likely to be overlooked of all valvular lesions, and this especially in the case of those soft murmurs, the prognosis of which is the worst possible, and in which it is therefore most necessary that a correct diagnosis be made. It must not be forgotten that the second is a double sound, and that it contains a pulmonary as well as an aortic element.

The Pulse Rate in Pulmonary Tuberculosis.—Thompson Campbell writes that an increase in the frequency of cardiac contraction, and a tendency to an evening rise of temperature, are well known as two of the earliest indications of a tuberculous process in the lungs. The results of study of tuberculous patients presenting themselves for treatment at sanatoria are as follows: There is an average decrease of 20 beats per minute from the count made when the patient presents himself for examination before admission, and that obtained during a week's confinement to bed. If, after a period of complete rest in bed, the pulse continues to run at or exceed 100, the outlook is not promising. Allowance must always be made for the possibility of overexertion, excitability under examination, and the presence of mitral stenosis. A pulse of 100 or more will usually be found to accompany an evening temperature reaching or exceeding 101°, and these two signs of grave import being persistently present in a case in which absolute rest has been enforced for some time, give little hope of treatment proving of any avail. As acceleration of the pulse is found at the onset of the pulmonary affection, so a gradual fall will be found to take place if a case is making progress toward recovery.

The Effect of Shock on Chronic Glaucoma.—H. Carter Mactier reports the case of a man aged sixty-one years, who for some time had been suffering from chronic glaucoma, but could see enough to do his work. One day he was accidentally thrown into a canal basin, injuring his knee; when removed from the water he was quite unable to see. For a few weeks vision improved, but never attained the sharpness present before the accident. Except for the slight improvement mentioned, he has grown steadily worse. This injury to vision was undoubtedly caused by the shock he sustained.

The Development of Filaria Nocturna in Different Species of Mosquitos.—George C. Low sums up the facts of this subject as follows: Some mosquitos are inefficient hosts, the embryos never migrating from the stomach; some are partially efficient, the embryos reaching the muscles, where they undergo a partial development and then become absorbed; while others are properly efficient, the time taken for complete metamorphosis varying with the temperature and other climatic influences of the place in which the experiments are conducted.

The Lancet, June 1, 1901.

Acroparæsthesia, Erythromelalgia, Sclerodactylia, and Other Angio-Neurotic Disturbances.—T. D. Savill reports a series of clinical cases and makes the following general clinical classification of vasomotor disorders of the extremities: A. Vaso-dilatation.—(*a*) Early stage (chronic).—Attacks of redness (congestion) and tingling, burning, etc. (congestive acroparæsthesia). (*b*) Late stage (chronic).—The symptoms are attended by swelling which gradually becomes permanent (erythromelalgia). (*c*) If the process takes an acute course the symptoms go on to gangrene, usually moist gangrene (Raynaud's disease—congestive or asphyxial type).

B. Vaso-constriction.—(*a*) Early stage (chronic).—Attacks of pallor and bloodlessness (ischæmia) attended by numbness, tingling, "pins and needles," "dead fingers," etc. (ischæmic acroparæsthesia). (*b*) Late stage (chronic).—The symptoms may be attended with thickening (sclerosis) of the skin and subcutaneous tissue (sclerodactylia). (*c*) If the process takes an acute course, dry gangrene probably results (Raynaud's disease—syncopal type).

It will be seen that these varieties correspond to the different varieties and phases of Raynaud's disease, which begins in one or other of the above ways and may go on to gangrene. These cases are also probably related to the condition described by Meige and others under the name of "chronic hereditary atrophœdema."

Arterial Hypertonus and Arteriosclerosis; their Relation and Significance.—W. Russell believes the following to be the relationship between the two conditions: Recurring or continued hypertonus leads to hypertrophy of the muscular media of the arteries under the physiological law that increased action in muscle leads to its hypertrophy. This accounts for the thickening media. The thickening intima is to be explained by the circulation in the blood of deleterious substances of various kinds; these substances act on the subendothelial connective tissue, irritate it, and lead to its hyperplasia. We thus get the completed picture of arteriosclerosis. The evolution of the changes occupies a varying time in different persons; in some the hypertonus comes early in life, and in early middle age sclerosis is established. In some there is little physiological error, hypertonus is but an occasional occurrence, and sclerosis appears late in life. The capability of the arteries to contract when an excess of toxin is present is in his experience seldom lost, and that is the reason why the recognition of it in sclerosed vessels is a matter of such great practical importance. While for the present he does not deal with the behavior of the capillaries, it is not to be understood that he ignores their presence, their reactions, or their influence in some of the conditions touched upon in this paper.

The Bacteriology of Sporadic Cerebro-Spinal Meningitis.—W. Hunter concludes by stating (1) that in all the cases of meningitis examined by him a diplococcus has been isolated from the cerebro-spinal fluid. In nine of these the fluid was obtained by lumbar puncture during life. (2) That this diplococcus has the same morphological and biological characteristics as Weichselbaum's diplococcus intracellularis meningitidis. (3) That in some cases the diplococcus was present in pure culture, in others associated with other micro-organisms—*e.g.*, bacillus influenzæ and bacillus tuberculosis. (4) That the clinical picture and the pathological changes found in these cases are those met with in so-called "posterior basal meningitis." (5) That in all probability "posterior basal meningitis" is simply a sporadic manifestation of cerebro-spinal meningitis and is produced by the same micro-organism—namely, the diplococcus intracellularis meningitidis.

Blue Urine.—By J. Good. The patient was a man aged forty-three years, who presented a train of symptoms which the author referred to duodenal indigestion. The urine was of a peacock-blue color with a specific gravity of 1.010, contained no albumin or sugar, but turned a rose color when boiled with hydrochloric acid. Under saline aperients, bitter tonics, and sodium salicylate the patient made a good recovery. The author thus explains the color found in this particular specimen: Trypsin in the small intestine breaks up proteid into peptone, peptone into leucin and tyrosin, and further into indol, phenol, and other bodies. Indol by the putrefactive action of bacillus coli in the intestine forms indican—*i.e.*, potassium indoxyl sulphate. When urine boiled with hydrochloric acid gives a pink color it indicates that indican is present in excess. Indican turns indigo blue by oxidation.

French Journals.

Ought the Starches to be Eliminated from the Nourishment of Very Young Children?—Borde, although admitting that mother's milk ought normally to form the nourishment of the infant, still, when this is impossible to procure, believes that aqueous solutions of starches should be combined with cow's milk for feeding. These decoctions are soothing to the intestine. They are also nutritious. In the starches he includes the starch of the potato, tapioca, starch of wheat, arrow-root, etc., also the decoctions of rice, barley, oatmeal, etc. He emphasizes the advisability of making these decoctions with water, not believing in their efficacy when cooked with milk. But milk can be mixed with the prepared decoctions with benefit. He concludes that: Aqueous decoctions of starch are digested by very young infants; they do not irritate the

intestines, but exert a soothing influence, preventing the acute infectious gastro-enteritis of summer; they also aid in curing these affections by replacing advantageously cow's milk and even mother's milk during the acute stage of these maladies. These foods are very nutritious, preventing rachitis and chronic digestive troubles in the babe brought up on cow's milk; the best of these is oats coarsely ground, which contain, besides the starches, albumens and assimilable vegetable phosphates, very useful in the dietary of the child. These starches should first be cooked in water and the resulting product mixed with milk.—*Gazette Hebdomadaire des Sciences Médicales de Bordeaux*, April 28, 1901.

Anal Fissure and its Treatment.—Tillaux states that anal fissure is very common, extremely painful, and calls for intervention. The three classical symptoms are: The wound; contraction of the external and internal sphincter; pain. The writer adds that it has been demonstrated that forcible dilatation of the anus gives absolutely the same clinical results as incision, *i.e.*, it is followed by a complete cure, and this is immediate. It is probable that this comes about from an elongation of the nervous filaments, which is to-day considered a curative measure for neuralgias in general. The muscular fibres are not torn. The writer uses the index finger of each hand introduced successively into the anal orifice, and drawn back till they touch the ischium. This transverse dilatation is sufficient. All possible precautions should be taken to avoid untoward accidents. The patient lies on the side with one leg flexed, the other stretched out, so that the anus is exposed. When anæsthesia develops, the dilatation is accomplished at the first trial and not by successive slight dilatations. Chloroform overcomes the resistance of the sphincter.—*Le Bulletin Médical*, May 25, 1901.

Strangulation of Pelvic Tumors by Torsion of the Pedicle.—Léon Bérard concludes that strangulation of pelvic tumors by torsion of the pedicle demands operation in like manner with strangulated hernia. The abdominal method is preferable to the vaginal, for this alone permits the observation of the lesions above and their appropriate treatment. The third or fourth day is generally soon enough for operation. If a second tumor be discovered, it may also be removed or it may be left for a future operation, according to the gravity of the troubles it is causing, and according to the general conditions of resistance of the patient.—*Gazette des Hôpitaux Civils et Militaires*, May 11, 1901.

Lateral and Circular Suture of Veins.—G. Clermont declares that venous suture absolutely arrests hemorrhage, is not dangerous, and preserves the integrity of the vessel. The lateral and even the circular suture is not difficult for a surgeon accustomed to the delicate operations on the biliary channels, on the ureter, etc. The operation does not take much time: a few minutes for the lateral suture, a half-hour for the circular suture. Of course it is necessary to observe the principles of asepsis.—*La Presse Médicale*, May 18, 1901.

Sarcoma of the Vagina, of the Uterus, and of the Pelvis.—Piéchaud and Guyot report the case of a child aged twenty months, who two months previously had had an abundant metrorrhagia, after which there appeared at the vulva a red, smooth tumor, part of which became gangrenous and sloughed off. The tumor disappeared for a few days, then reappeared. On examination the child was found to have a tumor filling up the pelvic cavity. The child died without treatment.—*Journal de Médecine*, May 19, 1901.

Berliner klinische Wochenschrift, May 13 and 20, 1901.

Nervous Tachypnœa.—Reckzeh, in investigating eleven hundred and fifty-five cases of functional neuroses, found forty instances of tachypnœa and gives their histories in brief. In all of these the respiration rate exceeded forty to the minute, and all organic lesions that might have been responsible for the condition could be excluded. Fourteen of the patients were men and twenty-six women, the former being the victims of neurasthenia or traumatic neuroses and the latter, almost without exception, hysterical. As etiological factors, in general, the usual conditions causing the allied disorders were found. Heredity is important; in one case both parents and five brothers were affected in the same way as the patient. Other factors were fright, alcohol, psychic depression, and severe bodily injury, while disorders of the sexual sphere were recent in a large number of the cases. The nature of the dyspnœa, as well as the manner of its appearance, was very variable, occurring in some cases only rarely and under excitement, while in others it persisted almost constantly. The mechanism of the affection is not very apparent, though the theory of Landgraf ascribing it to hysterical contraction of the bronchi is hardly tenable, and the trouble seems to fall most naturally into the same group with the tachycardia and diarrhœa often found allied with it and representing external manifestations of the underlying hysteria or other neurosis. There is probably some central stimulation of the vagi, though whether peripheral agencies, such as impulses from the skin and genitals, are also concerned is impossible to say, and it is not unlikely that several factors come into play. The diagnosis is easy when organic lesions can be excluded and other evidences of neurosis are present; the prognosis in general is good. The treatment is partly symptomatic (morphine, bromides, sulfonal, cardiac sedatives, ice, antipyretics) and partly directed to the neurasthenia (valerian, hydrotherapy, electricity); oxygen inhalations are valueless.

The Oxalic Acid of the Organism.—Cipollina says that authorities are now agreed that the oxalic acid of the urine has a double source, originating both in the metabolic processes of the organism itself, and being absorbed and excreted from already existing amounts taken in with the food. In order to determine the relative importance of these two factors, as well as what particular organ is most concerned in the formation of the substance within the animal body, the author made a series of analyses of the more important viscera, and of a considerable number of the vegetable food products in common use. The figures obtained show that oxalic acid is present in small amounts in the organs of man and animals, the largest amount being found in the thymus gland, and of the organs of adult life in the spleen. The total amount in the whole body, although small, is still about ten times as large as the maximum quantity excreted by the kidneys. Vegetables containing appreciable amounts of the acid are, in order of strength: carrots, a variety of mushrooms, cauliflower, cabbage, cucumbers, green beans, turnip-cabbage, sorrel, and spinach. While attempts at accurately locating the source of the acid in the body are not very satisfactory, it is highly probable that the spleen, and perhaps also the liver and muscles, can elaborate this substance from uric acid by oxidation.

The Detection of Small Amounts of Free Fluid in the Abdominal Cavity through the Inguinal Canal.—Criegern describes a simple manœuvre which, he says, enables him to make out fluid in the abdomen in quantities too small to be distinctly palpable by the usual method. The patient stands while the examiner, seated before him, introduces the index finger as far as possible into the inguinal canal. Tapping the abdomen with the other hand in the presence of fluid produces a distinct fluid wave, which is easily distinguished from the vibration of distended gut or subcutaneous fat.

Münchener med. Wochenschrift, May 14 and 21, 1901.

The Different Forms of "Hereditary Degeneration" from Clinical and Biological Points of View.—Adler takes up various of the neuroses, such as periodical depression, agoraphobia, claustrophobia, folie du doute, delire du toucher, etc., and ascribes them to a diminished power of resistance to emotional stimuli. Degenerative disturbances of the association organ and projection system may give rise to functional, nutritive, and formative manifestations, all depending on insufficient reproductive power of the nervous system of the ancestry, which was incapable of fully equipping the association and projection systems with the necessary amount of nutritive, formative, and functional energy. If there is deficiency of the formative function, we have inadequate development of nerve parenchyma with structural defects ranging from complete absence of the cerebro-spinal axis or the entire nervous system to anomalies in separate nerve fibres, asymmetry, heterotopy of the gray matter, agenesia of portions of the brain or spinal tracts, etc. If it is the nutritive power that is at fault, there appear temporary or permanent losses of nutrition, such as relapsing psychoses or hebephrenia respectively. The premature decay of certain parts is also dependent on this defect, and results in such lesions as progressive muscular atrophy, hereditary ataxia, amyotrophic lateral sclerosis, progressive bulbar palsy, etc. Functional deficiencies show themselves in the neuroses, sexual perversion, ethical defects, migraine, epilepsy, hysteria, myasthenia, etc. The degenerative lesions of the association and projection systems may manifest themselves in the most varied combinations, which may affect the formative, functional, or nutritive qualities singly or in combination, and in one or both provinces, so that it seems that the nervous system as a whole derives its forces from one and the same source, and therefore represents an ontogenetic entity.

Reflection on the Prophylaxis of Venereal Diseases.—T. Marschalko, while himself an advocate of the system, believes that none of the methods of legalized control now in use greatly restricts the spread of venereal disease, while, on the other hand, the partisans of "abolition" are too sanguine in their expectations. The plan of systematic registry of fallen women is bound to be ineffectual, because, while the inmates of licensed establishments are

readily kept under observation and can be subjected to regular medical supervision, it is the clandestine prostitutes, who are ostensibly engaged in other occupations, and are therefore entirely out of reach of surveillance, who are the most prolific sources of infection. Owing to this and many other difficulties in the practical carrying out of such systems, the results which so far have been reached in this way in the case of syphilis are almost negligible, and for gonorrhœa are entirely so. The recent congress at Brussels has shown that there is at present no hope for improvement or radical change in the systems of legalized control, and in view of the prevalent tendencies it does not seem far-fetched to hazard the opinion that the abolitionists will soon succeed in entirely doing away with those already existing, and which as a matter of fact are more or less dead letters at the best. The most effectual method of meeting the problem seems to lie in the education of the public in the individual precautions to be taken to avoid infection, such, for example, as the instillations devised by Credé to be practised immediately after coitus, and which have been shown to be a reliable prophylactic against gonorrhœa.

The Inhalation of Atomized Liquids.—M. Saenger has made a series of experiments intended to show the behavior of solutions brought into contact with the respiratory organs by atomization. The author believes that the mere fact that larger or smaller quantities of such liquids are to be found in the lower air passages after inhalation is not proof of their penetration to those areas while still in the nebulous state, for a considerable portion of the inhaled cloud condenses on the posterior pharyngeal wall, whence it may reach the larynx and even deeper parts by dripping down, diffusion through the coating of mucous secretion, and by imperfect attempts at swallowing made during the course of the inhalation, as well as through the force of the inspired air, which is able to carry the condensed vapor into even the deepest regions of the respiratory tree. While it is not to be denied that small amounts of the inhalation may penetrate to the larynx, trachea, and perhaps the coarser bronchi in an unaltered state, such quantities are too minute to have any therapeutic value, and that any of the medicament should still be in atomized form when it reaches the smaller and smallest bronchi seems wholly impossible.

An Observation on the Virulence of the Contagium of Scarlatina.—F. Schmidt emphasizes the necessity for prolonged isolation after this disease, and illustrates his theme by the citation of a case in which the infection was transmitted after a lapse of eleven weeks. The patient was a primipara, who passed through an uncomplicated labor and then was placed in a bed which had previously been slept in by her husband. A day later she developed prodromata, which speedily revealed themselves as the forerunners of a scarlatinal infection of unusual severity with delirium, weak heart (pulse 160), and Cheyne-Stokes respiration. As soon as the nature of the case was evident, inquiry revealed the fact that the husband nearly three months previously had been treated for a light infection of the same nature while on military service, and that his skin was still actively desquamating. Other sources of infection could be excluded, and the patient made a good recovery in spite of the gravity of the case.

A Case of Noma with Extensive Thrush Infection in Advanced Age.—Zusch describes this case, which was that of a man aged sixty-six years, suffering from senile dementia with increasing cachexia. The first sign of trouble was a moderate swelling of the cheek, soon followed by the beginning of the thrush formation. A necrotic area developed in the centre of the fungous patch, and in spite of active antiseptic treatment the breaking down advanced rapidly, perforated the cheek, and caused the whole side of the mouth to slough away. At the autopsy very advanced arteriosclerosis was found with multiple aneurisms, while the muguet growth was seen to have invaded pharynx, œsophagus, epiglottis, larynx, and trachea.

How Should the Stump be Shaped that is Left Behind after Thyroid Operations?—E. Mensel refers to the poor cosmetic results often following goitre operations, which, while they may relieve the important symptoms, still frequently leave the patient dissatisfied with the appearance of her neck. In trimming the stump into shape it is better to do so by horizontal cuts, to leave the anterior surface uncovered by capsule, and to make it broad and flat. By the use of these precautions and with Kocher's skin incision the results are always satisfactory, and secondary plastic operations are not needed.

Deutsche med. Wochenschrift, May 23, 1901.

Pulsating Pleurisy.—J. Kullman says that in most instances when pleuritic exudate has given rise to diffuse pulsation the fluid has been purulent, and then describes a case in which clear serum was found. The patient was a man aged forty years, from whose left chest over three pints of fluid had been removed two weeks before he came under observation. At this time there was slight dyspnœa; the lower portion of the thorax on the left side was very prominent, and the intercostal spaces were obliterated. The left chest was the seat of a vigorous pulsation synchronous with the apex beat, but exceeding it in force, while in the third right intercostal space there was a much weaker impulse. The pulsation extended from the second interspace anteriorly, and the angle of the scapula behind to three fingers' breadths below the free costal margin; percussion and auscultation gave typical signs of fluid. On aspiration more than three quarts of serum were obtained, after which the signs disappeared and the patient made a rapid recovery. The phenomenon appears to have depended on great tension of the fluid with strong heart action, with the result that there was relaxation of the intercostal spaces either depending on the overdistention or due to inflammatory changes. The compressed lung acted as a favorable medium for the transmission of the heart's impulse, while the pulsation of the right of the sternum was probably due to the displacement of the whole mediastinum.

Further Contributions on the Germ of Vaccinia and Variola.—M. Funck, in a preliminary report, says that the organism of variola is more easily studied than that of vaccinia, and that it seems to multiply *in vitro* more readily than the allied form. The same three types have been found in, and the spores cultivated from, variola pustules as in vaccinia. These are (1) spores, consisting of rounded bodies 2 to 4 μ in diameter, which do not stain either with osmic acid or Soudan. (2) Intracellular forms which are more or less elongated, egg-shaped cells, easily distinguished from those of the sebaceous glands by the Soudan reaction, and which probably represent epithelial cells that have been invaded by the parasite. (3) The third form is a rounded cyst found in most of the lymphs examined, its diameter is from 15 to 20 μ; it does not stain with Soudan or osmic acid and contains a variable number of spores.

Therapeutic Monthly, May, 1901.

Atropine as a Physiological Antidote in Morphine Poisoning.—Edward T. Reichert, from a long series of experiments, concludes that atropine may be of value as antidote in morphine poisoning, but only before the third stage, and then only when given in small or moderate doses. Even here its usefulness is practically limited to a possible excitation of the respiratory movements and a stimulation of the circulation, both of which, however, may be fully compensated for in its pernicious effects, chiefly upon general metabolism. Given in large doses, during the second stage, or in moderate to large doses during the third stage, it almost without exception does harm by intensifying the morphine condition, prolonging or shortening but intensifying the second stage, or shortening the third stage and hastening the fatal issue. If the second stage is shortened, it is owing to the earlier development of the third stage of the poisoning. A dose of morphine that is not lethal may be made so by the synergistic action of a sublethal dose of atropine.

Carbolic Acid as an Internal Remedy.—S. Henry Dessau considers this an entirely safe remedy when used judiciously, in free dilution, the dose graduated to the age of the patient. It is the rational remedy for the treatment of germ diseases. Its internal administration in solution by way of the stomach is safer than in the form of enema or as a local application. There are no reactionary manifestations nor cumulative effects. It gives good, speedy, and permanent results even under the most unfavorable conditions, and is a remedy which has been too long neglected.

Archives of Pediatrics, June, 1901.

A Report of Two Cases of Cancrum Oris.—William Seaman Bainbridge reports the case of two patients at Randall's Island. In the first, half of the body of the upper jaw on either side was removed, the under surface of the lip was curetted and the denuded areas were cauterized with pure nitric acid. The after-treatment consisted of douching with peroxide of hydrogen followed by a saturated solution of boric acid. Fluid diet, strychnine, and whiskey were given. A second operation was necessary, but in spite of it the gangrene spread and the child died. In the second case the disease was treated at an earlier period; the intermaxillary bone with its teeth was removed and the superior maxilla on both sides gnawed away by a rongeur. The child is seemingly perfectly well. The upper jaw is largely filled in, the only evidence of any previous trouble being the absence of upper teeth.

Duhring's Disease in Childhood.—William S. Gottheil reports two cases of this disease, which looks like an eczema

at first, in the itching, multiformity, and primary lesions. But the pruritus is excessive, the malady very chronic and obstinate. The usual treatment for eczema is entirely unavailing to prevent recurrence of attacks. All treatment, indeed, is unsatisfactory, and the author now restricts himself to general tonic and hygienic measures, and believes that change of air and scene is more efficacious than any drug. Locally, any of the bland or cooling salves, or ichthyol in five- or ten-per-cent. solution or ointment may be employed.

Abscess of the Ethmoid and Antrum of Highmore.—J. Morrison Ray reports a case. He operated, taking away a large portion of the front wall of the superior maxilla, and entering a cavity which involved both the ethmoid and the antrum of Highmore. The child has improved rapidly.

The Practitioner, May, 1901.

The Ovary as an Organ of Internal Secretion.—By W. E. Dixon. From a study of the anatomy of girls in savage tribes, where double ovariotomy is often done before the arrival of the age of puberty, the effects of ovarian growth and development are at once suggested. The girl takes on the masculine rather than the feminine adult type. The ovaries appear to have a distinct relation to the mammæ. Lactation may occur at full-term gestation after ovariotomy; so, also, gestation may occur after removal of the mammæ. There appears to be no doubt that metabolic changes do not occur in an animal unless the ovaries have been completely removed, or, in other words, there is no difference (physiologically) between an animal with only half an ovary and one with two ovaries; and if one is removed the other undergoes a compensatory hypertrophy, as in the case of certain other organs, such as the kidney. From the clinical evidence three points seem to be clearly demonstrated: first, that the presence in the body of ovarian tissue, however small in amount, is sufficient to prevent the distressing symptoms which frequently arise after complete double ovariotomy. It does not appear to matter in what position in the body the portion of ovary remains, and even a transplanted ovary is sufficient to prevent the untoward consequences. Secondly, the administration of ovarian tissue by the mouth exerts a beneficial effect in patients in whom menstruation has ceased in consequence of disease or complete ovariotomy, and many physicians advocate its use during the menopause. Thirdly, ovariotomy has a distinct effect on metabolism, as shown by the diminution in gaseous metabolism, the increase in body weight due to deposition of subcutaneous fat, and the diminished excretion of P_2O_5 in the urine. In conclusion, it may be asserted that the ovaries exert a decided influence over the organism as a whole, and all evidence is strongly in favor of the theory that this influence is the result of an internal secretion which favors katabolic changes.

Composition and Action of Orchitic Extract.—By W. E. Dixon. Extract of testis made with distilled water is alkaline; it contains a large percentage of proteid, which is almost entirely nucleo-proteid. This may be precipitated by acetic acid, and if the precipitate is filtered and dissolved in a solution of Na_2CO_3 its action can be separately determined. Frequent precipitation and solution, however, alter its chemical composition and render it inactive, while even a single precipitation and solution profoundly modify its action. After precipitation with acetic acid only a trace of proteid remains. Orchitic extract also contains a number of extractives, among which is spermin; but others in equal quantity, and probably at least as important, are present. Other substances which can be readily detected are lecithin and cholesterin. Inorganic salts are found in the ash in considerable quantity—about 7.5 per cent. of dried ram's testis; they consist of chlorides, sulphates, and phosphates of sodium and potassium; a little calcium is also present. Alcoholic extracts of the testis, watery extracts which have been boiled and filtered, and spermin produce identical results when injected into animals. All these bodies when injected into the circulation produce a fall of blood pressure with slight cardiac slowing, followed by a rapid recovery. This effect is largely cardiac, due to stimulation of the peripheral ends of the vagus in the heart, and if these have been previously paralyzed by an injection of atropine the fall of pressure is not produced. Another and very important effect of these substances is the vasodilatation to which they give rise. This is especially well seen in the splanchnic vessels, but the limb and other vessels also show the effect. The action is still produced when administration is by the stomach, and in this case an increase in the "volume pulse" is usually recorded in about ten minutes. All this group of bodies stimulate involuntary muscles and slightly increase peristalsis.

The Therapeutic Value of Suprarenal Preparation in Addison's Disease.—By C. R. Box. Six cases were treated. Results were, on the whole, disappointing. The diagnosis of the malady in question is generally made late in the disease, and it has sometimes proved impossible, on account of constant vomiting, to administer the suprarenal substance by the mouth, and rectal feeding or subcutaneous injection has been resorted to. The results of the author's experience in the group of cases lead him to conclude that: (1) The active substance has not been properly administered; or, (2) the requisite material is not present in the suprarenal bodies as at present prepared for administration; or, (3) the lack of a certain internal secretion is not the sole or predominant factor in Addison's disease.

Bull. of Johns Hopkins Hosp., April, May, June, 1901.

A Composite Study of the Axillary Artery in Man.—J. M. Hitzrot concludes that, while the origin of the subdivisions of the axillary artery varies, the distribution is practically constant. The type most constantly found differs from the text-book descriptions by the absence of the long thoracic artery. The branches in this type can be conveniently arranged as follows:

- Part I.
  - 1. Superior thoracic.
    - 1. Thoracic branch.
    - 2. Acromic-humeral branch.
    - 3. Clavicular.
  - 2. Acromic-thoracic.
- Part II.—No branches.
- Part III.
  - 1. Subscapular.
    - 1. Dorsal scapular,
    - 2. Muscular branches.
    - 3. Anterior.
    - 4. Posterior.
  - 2. Anterior circumflex.
    - Ascending branch.
    - Anastomatic.
  - 3. Posterior circumflex.
    - Muscular.
    - Anastomatic.
  - 4. Muscular branches.
    - Coraco-brachialis.
    - Biceps.

The long thoracic artery and alar thoracic arteries are most frequently absent, and their areas of distribution are supplied by the adjacent branches from the main artery.

Retrojection of Bile into the Pancreas, a Cause of Acute Hemorrhagic Pancreatitis.—W. S. Halsted reports the case of a man aged forty-eight years, who had been subject to attacks of "indigestion," attended by pain in the epigastrium and a feeling of distention, for several years. At the time the writer saw him he was walking about the room excited and nervous and his teeth chattering; he seemed to be in great pain. His pulse was full and regular—92 the first count and 87 the second. He could not keep quiet. He was sensitive to pressure over the epigastrium, the point of greatest tenderness being a little above and to the right of the umbilicus. He was somewhat cyanosed. The print of the examinating fingers could be seen on the abdominal wall. He was thought to be suffering from gall stones. He was operated on the next morning and died within twenty-three hours. When the abdomen was opened through the middle line blood-stained fluid escaped and the omentum showed many fat necroses. The omental bursa was opened; the entire region of the pancreas could be palpated. The tissues over this organ were slightly infiltrated with blood-stained serum, but no tumor mass was made out. The common bile duct was distended to the thickness of an index finger, but no stone in the diverticulum could be felt. At autopsy, after careful search and probing of the papilla, the presence of a minute stone was determined.

Remarkable Cases of Hereditary Ankyloses, or Absence of Various Phalangeal Joints, with Defects of the Little and Ring Fingers.—George Walker speaks of several of these cases. The first was that of a child in whom there was a lateral fusion of the first and second metacarpal bones of the feet. This was not supposed to be hereditary until the grandmother, upon examining her own foot, to show where the defect had occurred in the child, found her own bones in exactly the same condition. She was seventy years old. The second case was in a young girl who had a partial stiffening in the metacarpo-phalangeal articulation of the thumb; this was ligamentous and not bony, and permitted a certain amount of motion, probably about one-half that of normal. The defect had occurred in one brother, one uncle, her father, and her grandfather. All of them were defective in the same joint, and had about the same amount of motion. In another case, that of a man aged fifty-two years, the thumb and index finger were normal, but there was entire bony ankylosis of the second metacarpal joints of the ring and middle fingers. The little finger presented only two phalanges. This defect occurred in various members of his family.

Note on the Basement Membranes of the Tubules of the Kidney.—Franklin P. Mall macerated frozen sections of the rabbit's kidney in a cold saturated solution of bicarbonate of sodium for a number of days, after which most of the cells were converted into a slimy mass. Shaking the section vigorously in water cleared the framework, which was spread upon a slide and examined. If most of the cell remnants had been removed, the section was dried upon

the slide, stained with acid fuchsin, differentiated with picric acid, and mounted in balsam. The basement membranes were partly filled with the remnants of epithelial cells, the interstitial reticulated connective tissue, and the blood-vessels. The membranes are not elastic, as they do not take on Weigert's elastic-tissue stain, while the elastic-tissue fibres do. Mallory's connective-tissue stain stains the reticulum but not the membranes. So far, the basement membranes have given reactions much like the membranes of elastic fibres, but whether they are identical the writer has been unable to determine.

The Etiology of Acute Hemorrhagic Pancreatitis.—Eugene L. Opie concludes that: (1) A small gall stone impacted in the diverticulum of Vater may occlude the common orifice of the bile duct and duct of Wirsung and convert them into a continuous closed channel. Bile enters the pancreas by way of the pancreatic duct, and the pancreas becomes the seat of inflammatory changes characterized by necrosis of the parenchymatous cells, hemorrhage, and the accumulation of inflammatory products. Anatomical peculiarities of the diverticulum of Vater do not permit this sequence of events in all individuals. (2) Injection of bile into the pancreatic duct of dogs causes a necrotizing hemorrhagic inflammation of the pancreas resembling the human lesion, and like it accompanied by fat necrosis. Necrosis of the parenchymatous cells and hemorrhage represent the primary action of the bile; an inflammatory reaction rapidly follows. (3) The frequent association of cholelithiasis with hemorrhagic and gangrenous pancreatitis is the result of impaction of gall stones in the orifice of the diverticulum of Vater and penetration of bile into the pancreas.

Normal Menstruation and Some of the Factors Modifying it.—Clelia Duel Mosher states that a rhythmical variation of blood pressure, at definite intervals, occurs in both men and women. The fall in pressure in women occurs near or at the menstrual period. In every case that has been observed the fall of blood-pressure was gradual from the mean average pressure. The variations in blood pressure are not peculiar to either sex. The sense of maximum efficiency of the individual corresponds to the time when the pressure is high and *vice versa*. Much of the so-called menstrual suffering is not dysmenorrhœa but simply coincident functional disturbances in other organs, induced, possibly, by the favoring conditions of a lowered general blood pressure occurring near or at the time of menstruation.

On the Occurrence of Tails in Man, with a Description of the Case Reported by Dr. Watson.—Ross Granville Harrison reports Watson's case. The patient was a healthy, well-developed male, the third child. The tail appendage was attached in the mid-line about 1 cm. below the tip of the coccyx. There was a well-marked foveola coccygea. The appendage was firm, though it contained no bone. It was covered with normal skin, containing fine hairs, and was apparently well vascularized. There were three distinct segments. Two weeks after birth, the tail was 4.4 cm. long. At six months, when it was removed, it measured 7 cm. It was very movable. When the child was irritated and cried or coughed, the tail would contract markedly.

Annals of Surgery, June, 1901.

A Loop Around the Hyoid Bone as an Aid in Narcosis during Certain Operations on the Lower Jaw and in the Mouth and in After-Treatment.—After resection of one-half of the lower jaw, C. Fenger allows a loop of silver wire or silk, passed through the anterior portion of the divided bone, to remain, the ends being brought out through the dressing, so that the nurse or patient might pull on it if dyspnœa should arise. This precaution is sufficient only when the muscles extending from the hyoid bone to the maxilla are intact on one side, and if it can be seen during the operation that the entrance to the larynx is made free by traction on the end of the bone left. In case of removal of the floor of the mouth for malignant tumors, when all the muscles from the body of the inferior maxilla backward to the tongue and hyoid bone are removed, the tongue and larynx with the epiglottis have necessarily lost their attachment to the maxilla, and will sink backward against the posterior wall of the pharynx, causing occlusion of the entrance to the larynx and strangulation, especially during sleep. During narcosis, this difficulty is obviated to a great extent if the tongue can be pulled out of the mouth in a longitudinal direction. This cannot be accomplished when the jaws are closed and fixed, so that the mouth cannot be opened nor access gained to the tongue, as in operations for osseous ankylosis of the jaw. It is impossible for the assistant who gives the anæsthetic to hold a sharp hook around the hyoid bone for a long time, possibly for hours, while he can manage a loop of silk passed around the hyoid bone just as easily as a loop passed through the tongue. Moreover, it is impossible to keep the pharynx perfectly free from frothy mucus. If one-half of the entrance to the larynx be obstructed, the inferior half lying against the wall of the pharynx, there is no space for the mucus, and therefore it must be aspirated down into the larynx, and the air must pass through it and tend to bring it down. On the other hand, if the larynx is perfectly free, and if there is more room behind it than is actually necessary, there will be less aspiration of mucus, and possibly less bronchitis or broncho-pneumonia, following the operation.

The Operative Treatment of Cirrhosis of the Liver.—C. H. Frazier reports one successful case, making the fourteenth thus far recorded. Excluding those in which there was some error of technique, those in which there was an error in diagnosis, and those in which the operation was contraindicated, but eight cases remain. Of these patients none died (mortality, 0 per cent.), one was living and unimproved (12.5 per cent.), one living and improved (12.5 per cent.), and six were living and free from ascites at periods of three, four, six, twenty-four, and twenty-six months respectively (75 per cent.). Frazier believes that the operation has a future under the following conditions: (1) Cases in which the liver is cirrhotic; (2) those in which there is reason to believe the liver-cells are not devoid of function; (3) those in which internal medication (particularly iodide of potassium) and paracentesis fail to afford relief, or, in other words, in utterly hopeless cases, and (4) those in which there is no reasonable contraindication.

Angina Ludovici.—G. C. Ross reports two cases, both of which resulted in recovery. He believes that some cases of Ludwig's angina are essentially erysipelatous in character, and that in the wards of a general hospital they should be isolated.

American Journal of the Medical Sciences, June, 1901.

Chronic Myocarditis and Fatty Degeneration of the Heart.—Beverley Robinson states that clinically these two expressions of cardiac degeneration are frequently most difficult to differentiate accurately. It is almost impossible prior to death and direct examination of the heart to state positively just what shall be found, so far as the precise changes or the limitations of the morbid involvement of the coronary arteries and heart muscle are concerned. In old valvular troubles of the heart, whether they be of the nature of stenosis or regurgitation, in chronic pericarditis in which the adhesions are tough and fibrous, in an advanced condition of hypertrophy of the heart, with probably much cardiac dilatation, fatty degeneration is almost surely going to occur at a given time, provided the patient's life is sufficiently prolonged. If there be chronic myocarditis present, which occasionally occurs, the heart muscle is hard and resistant in spots and very often diminished in thickness where this exists, owing to the deposit of fibrous tissue which has practically caused many muscular fibres to atrophy, degenerate, or almost or completely to disappear. In those corpulent people who have accumulated flesh continuously, slowly, and in large amount, the heart is no exception to the great number of viscera which become more or less involved. All acute diseases in these obese persons are of moment, and what would be a relatively simple affair with a thin person or one with only moderate or healthful embonpoint is apt to take on a certain degree of gravity. In the young, the results are not apt to compare in gravity with those occurring in older patients. In women near the climacteric, especially, and in men near or past middle life, too much care cannot be taken, and the most judicious medical counsel must be given. In young girls, particularly, obesity is apt to follow acute disease like scarlet fever or typhoid, and to be allied with chlorosis. In no condition is the development of fatty degeneration more dreaded than in that of chronic alcoholism. Many cases of sudden death are attributed to so-called heart failure, which means nothing tangible or obvious, but which should mean fatty cardiac degeneration. In the senile heart, especially among those persons who have led a moderately careful and regular life, we are more inclined to diagnose fibrous changes than fatty ones if the heart begins to show decided weakness, irregularity, and intermittences. The writer has occasionally observed syphilitic gummata of the liver, and in connection therewith there have been fatty and fibroid changes. There is a natural growth and natural decay, and these fibroid changes in the heart and vascular circulation are to be wisely regarded as nature's showing in due season. Symptoms should be treated as they arise. Whenever the heart is notably affected with fibroid changes the muscle there becomes tougher and more resistant, besides showing thinning of the heart wall in places. In chronic fatty degeneration, especially if advanced, the color of the muscle is notably pale and yellow in places. There may be an overgrowth of pigment granules.

Cancer Distribution and Statistics in Buffalo for the Period 1880–1899, with Special Reference to the Parasitic Theory.—Irving Phillips Lyon summarizes the principal facts and

resnlts of his study as follows: (1) The house distribution of cancer on the map shows an area of marked concentration in the German wards. No other relation than that of race can be determined to exist between this area of concentration and local conditions. (2) The race table shows that cancer is many times more frequent among the foreign-born, and particularly the Germans, than the native-born. The latter fact is also verified by the United States census for twenty-eight large cities. (3) The Germans (and Poles) were further specially distinguished from other classes by the high rate (43.8 per cent.) of involvement of the stomach, 2.08 times the rate (twenty-one per cent.) shown by the native-born. Such high figures seem hard to explain on the embryonic theory, and tend to support the parasitic theory of cancer by supposing that the peculiar diet of the Germans is more liable to contamination with the parasite of caucer than the more ordinary diet of other classes. Cancer of the nterus and breast in Germans (and Poles) was correspondingly low. (4) The ratio of males to females, the latter taken as 100, was 93 for Germans (and Poles) and from 51 (native-born) to 61 (all Europeans except Germans and Poles) for all other races and classes. The high German male rate is probably directly dependent upon the high rate of cancer of the stomach (especially in males), and the low rate of cancer of the uterus and breast (females) found to characterize the German as opposed to other races. For all classes the ratio of males to females was found to have risen during the twenty years covered by the investigation. This rise was very slight for the native-born. (5) An increase in the general cancer rate from thirty-two to fifty-three per one hundred thousand of population (sixty-five per cent.) took place from 1880 to 1899. A similar increase has been shown in all countries. This increase is partly real and not entirely apparent. The rate of increase is shown to depend, in part at least, upon changes in the proportion of the foreign-born, because the cancer rate in the foreign-born is so much higher than in the native-born.

Heart and Circulation in the Feeble-Minded.—John Madison Taylor and F. Savary Pearce, from a detailed study of the circulation of seventy-two cases of feeble-minded children at the Elwyn School, have found a great number of varied cardio-vascular signs, and these out of proportion to the mental defect—so much so as to warrant assuming organic vascular heart disease to be a large etiological factor in continuing the downward course of imbeciles. They urge careful anthropometric studies and observations in detail of somatic disease other than that of the nervous system in cases of mental enfeeblement. There is no doubt that many of the high-grade cases can be bettered much more by attention being paid to therapeusis of the cardiovascular disorders of imbeciles, also of the insane. The laboratory studies of the blood and excreta will also furnish valuable data. The proper use of especially directed regulated movements will greatly help these afflicted beings. The mentality will be improved with the uplifting of the physical being. Overexercise should be carefully avoided. America undoubtedly leads in the practical application of these scientific truths which are being formulated for the proper care of the dependent classes.

Dublin Journal of Medical Sciences, April, 1901.

Stenosis of the Tricuspid, Mitral, and Aortic Orifices.—By Sir G. Duffey. One case is reported, the patient being a man aged thirty-two years. Autopsy findings are recorded in full. The special interest in the case centres about the tricuspid narrowing, the condition being diagnosticated during life. From a study of the various reported cases of this condition Duffey shows (1) that tricuspid stenosis is almost invariably associated with mitral stenosis; and that the constriction of the latter orifice is generally greater than that of the tricuspid opening. (2) That in the larger proportion of these cases (say twenty-five per cent.) of tricuspid and mitral stenosis there is also marked contraction of the aortic orifice. (3) That in at least fifty per cent. of the collected cases of tricuspid and mitral stenosis there is an antecedent history of rheumatism of some form or other; and that the stenosis is most frequently the result of an endocarditis of rheumatic origin, and probably never congenital. He also alludes to the fact that the autopsy records of Guy's Hospital show eighty-seven fatal cases of tricuspid stenosis out of twelve thousand autopsies during a period of twenty-six years.

The Edinburgh Medical Journal, May, 1901.

Medicine and Surgery in the Arctic Circle—James Laing says that although there are no diseases peculiar to the Arctic circle, scurvy, snow-blindness, snow-shoe sickness, and frost-bite are usually associated with Arctic explorations and hunting expeditions. In 1898 there were twenty-two cases of scurvy with six deaths on the Rat River, due probably to lack of exercise, imperfect cooking, and lack of cleanliness with cooking-utensils. Snow-shoe sickness consists of a teno-synovitis of the tendo Achillis, and more rarely of the tendons on the front of the leg. Rest, elevation, hot fomentations, and massage are the only remedies of any use. Snow-blindness is seen in the spring. Smoked glasses are useful. There were many cases of frost-bite, mostly superficial, but in some cases necessitating amputation of fingers and toes. The healing of wounds among the whites in the north is very unsatisfactory. Among the Indians the results are better. Tuberculous disease is prevalent among the Loucheux Indians, and even more among the half-breeds.

Note on the Cremasteric Reflex in Sciatica.—G. A. Gibson states that a remarkable exaggeration of the cremasteric reflex has shown itself in every case of sciatica that has recently been under his notice. It can be elicited in the ordinary way by gently stroking the skin on the inner side of the thigh, but is much more easily produced by firm pressure over the lower and inner portion of Scarpa's triangle, whose sensory nerve supply is derived from the internal cutaneous branch of the anterior crural nerve. The extent of the cremasteric reflex is greatest when the knee jerk is most exaggerated, yet it is found in cases which do not manifest much increase in the knee jerk. Anatomically, the cremasteric centre and the knee centre are situated above the connections of the sciatic nerve; it therefore seems probable that in sciatica the segments of the cord at and below these sciatic connections have but little tendency to exaggeration, while those above are in a condition of exaltation.

A New Treatment for Inoperable Cancer of the Breast.—By Cecil H. Leaf. In cases of nlcerating scirrhus adherent to the pectoral muscle, with enlarged axillary glands, and in cases of recurrent cancer after operation, his principle is to prevent dissemination, if it can be done. After much thought on the subject, he has concluded that suction action would best accomplish the purpose. He has had constructed a large vulcanite shield, which is made to fit accurately on the skin round the scirrhus, or the "recurrent nodules," as the case may be. As large a surface as possible is enclosed within its area. He describes the apparatus, which as long as it is in action it is hoped will constantly restrain the noxious agent from passing to the deeper lymphatics. Very little pain is caused. Absolute rest for the arm of the affected side must be insisted on. Four cases are reported in which the apparatus has been very successfully applied.

The Scottish Medical and Surgical Journal, May, 1901.

Myasthenia Gravis.—Edwin Bramwell describes a case of this disease, the most prominent symptom of which is the facility with which the muscles become fatigued by voluntary effort. A voluntary movement, which is at first perfectly carried out, becomes rapidly feebler each time it is repeated; finally, if persisted in, all power of performing the movement may be temporarily lost. A variable degree of persistent paresis is often present in the affected muscles. The rapidity with which the muscles become fatigued by the faradic current is especially characteristic of this disease; the term myasthenic reaction has been given to this condition. The disease is probably due to a toxin of endogenous origin, and the seat of the lesion in the motor nervous system, probably in the lower motor neuron. Some cases improve, but the disease is often fatal. No specific treatment is known, but the author suggests a number of palliative measures.

Diseases of the Nails Recurring with Each Pregnancy.—W. E. Foggie reports the case of a woman who in each of her seven pregnancies, except the first, has had a nail affection. It begins in about the fifth month with a sudden aching, hot, and painful feeling at the ends of the fingers and thumbs. The nails then begin to separate at their free margins and sides, and to be raised up from their beds by a scaly accumulation. Later the brittle nails were almost entirely broken off, leaving the nail beds completely exposed except for a small margin of healthy nail beginning to emerge from the nail fold. Treatment consisted in local use of tar ointment, and later of resorcin in rectified spirit, with the internal administration of arsenic and strychnine. The author considers the case to be an example of psoriasis of the nail bed.

The Sphygmographic Appearances of the Pulse in Infancy.—H. Oliphant Nicholson holds that the sphygmogram of the new-born infant's pulse is not the simple type of curve described by Ozanam, Keating, and Edwards. It shows a distinct percussion wave which forms a pointed summit to the curve, and the usual secondary waves are quite recognizable. It reveals all the characters of a relatively high-tension pulse. Dicrotism is as fully represented at birth as it is in any high-tension pulse. The summit of the pulse curves becomes more pointed, and the secondary waves are accentuated during the first year of life, but the pulse still remains of moderately high tension. Pyrexia in children under a year old rarely produces dicrotism or hyperdicrotism of the pulse.

The Food Requirement of Varying Labor.—James Cranford Dunlop concludes that an average man at light labor requires a diet of 3,100 calories; that if the labor is more than light he requires more food; that the increments to meet the wants of moderate labor may amount to about twenty per cent., and those for severe labor perhaps to fifty per cent. of the light-labor diet. Accepting these figures as correct, we are still unable to adjust a diet to meet the requirements of moderate or severe labor from standards, because we are unable to estimate with even approximate accuracy the severity of labor tasks.

Zeitschrift für klinische Medicin, vol. xlii., Nos. 5 and 6.

The Effect of Variations in Diet on the Secretion of Hydrochloric Acid and the Osmotic Tension of the Normal Human Stomach.—T. Justesen gives the following picture of gastric digestion. A meal whose insoluble carbohydrates have already undergone considerable change through the agency of the salivary ferments reaches the stomach, and immediately a solution of many readily soluble substances takes place and the gastric contents are converted into a more or less "gastro-hypertonic" mass. At once water and hydrochloric acid are secreted, and through osmotic currents various dissolved bodies, such as peptone, sugar, and alcohol, are absorbed. The hydrochloric acid, leaving the ferments out of account, is at once taken up in combination by those organic substances, particularly the albumens, which act as free organic bases. Later on the hydrochloric acid attacks the salts of the weaker organic acids and the carbonates, combines with their bases and converts them into hydrochlorates, and not until then does any of it become manifest, and together with the sodium chloride diffused from the blood begin to equalize the chloride tension. At the same time the molecular concentration of the stomach contents is reduced considerably below that of the blood by the "vital dilution secretions" of the epithelial cells. Meanwhile, at stated intervals portions of the food mass are being carried out through the pylorus, and Hirsch has shown that it is principally the more fluid elements that pass out first, the solid matters remaining behind longest, while Verhaegen has demonstrated, by means of a special tube, that the stomach contents are always more liquid at the pylorus than at the fundus.

Contributions to Hippuric-Acid Metabolism in Man.—C. Lewin finds that on an ordinary light diet consisting of milk, meat, bread, and fresh vegetables the healthy adult excretes from 0.10 to 0.30 gm. of hippuric acid daily, the amount being markedly increased when grape sugar is added to the food. Augmenting the amount of albumin increases intestinal putrefaction with a consequent rise in hippuric-acid excretion. The admiuistration of quinic acid raises the quantity excreted, while in many instances the uric acid undergoes a corresponding drop, a fact that tends to corroborate the theory of Weiss that a parallelism exists between the two. Under a nuclein diet, such as is afforded by thymus gland, a considerable rise in the hippuric-acid elimination takes place, which is probably to be explained on the ground of the increased intestinal putrefaction, for the administration of nucleinic acid is not accompanied by a similar change. Gout and diabetes are without effect in modifying the excretion of the substance, while in perityphlitis it is much increased. In febrile states, as well as in kidney affections, the hippuric acid excreted is never diminished, but rather is markedly increased.

The Bactericidal Power of the Bile.—S. Talma, as the result of a series of experiments conducted mainly by injecting various forms of bacteria into the gall bladders of rabbits, concludes that bile contains some constituent having a distinctly inhibiting effect on the growth of most colon, typhoid, and diphtheria bacilli. The susceptibility of various types of organisms to these substances is very variable, and the degree of virulence in the generally used sense is not a measure of infectiousness for the gall passages. The resisting-power of the bile is also an uncertain quantity, and at different times and in different animals varying grades of bactericidal power are exhibited. The number of the invading organisms is of great importance in determining their fate, and the epithelium of the gall passages and the liver cells themselves oppose powerful resistance to their penetration, especially in the case of the diphtheria bacillus.

The Steatolytic Ferment of the Stomach.—F. Volhard finds that the gastric juice contains a steatolytic ferment which possesses the property of splitting off fatty acids from emulsified fats. Like the pepsin, this ferment is produced principally in the fundus, and may also be extracted from the mucous membrane of this portion of the stomach by means of glycerin. It furthermore has the property of passing through clay filters, and is modified and finally destroyed in the presence of pepsin and hydrochloric acid. The well-known fact that fats cause the secretion of a gastric juice poor in pepsin and hydrochloric acid may perhaps find its explanation in this susceptibility of the new ferment, and a further argument is furnished in support of Pflüger's theory that all fats must be split up before absorption can take place.

The Etiology of Diabetes Mellitus.—A. Pollatschek doubts the prevailing impression that ascribes a racial predisposition to diabetes to the Jews, and in evidence cites the figures gained from his own experience. In a period of ten years in all 4,719 patients were treated, and of this number 2,381 were Christians, 2,333 Jews, and 5 Mohammedans. The diabetics numbered 653, and of these 289 were Christians and 364 of Semitic race, corresponding to 124 Christian diabetics per 1,000 and 155 Jews, a difference that hardly justifies the exaggerated ideas usually entertained.

Revue de Chirurgie, April 10, 1901.

Hæmothorax, Physiologically and Cytologically Considered.—Th. Tuffier and G. Milian hold that the increase in the exudation, which occurs about the fifteenth day, is not a continuation of the hemorrhage, but an exudation of serum, which can easily be proved by exploratory puncture. It does not therefore constitute an indication for operation. The accompanying fever is purely dynamic and not of microbial origin. The persistence of polynuclears in the exudate after the twenty-fifth day should cause suspicion of suppuration. The correct treatment of traumatic hæmothorax consists in capillary puncture toward the fifteenth day, at a time when dilution of the blood is appropriate, and when the pulmonary wound has so far healed that there is no danger of a fresh hemorrhage from the sudden relief of pressure on the lungs.

Primary Tuberculosis of the Parotid Gland.—P. Lecène reports the case of a tumor of the parotid gland, which was operated on and removed. The clinical symptoms and the macroscopic examination appeared to justify a diagnosis of mixed tumor, but a histological and bacteriological examination proved it to be a case of primary tuberculosis of the gland. Tuberculous affection of the salivary glands is very rare, but the author knows of nine cases. Total extirpation is unfortunately impossible, on account of injury to the facial nerve. Should the tumor be isolated, encapsulated, it can be enucleated, and its capsule cauterized or curetted.

Upsala Läkareförenings Förhandlingar, April, 1901.

Acute Peritonitis.—K. G. Lennander reiterates statements that he has already made concerning the sensibility of the peritoneum, viz., that it is the parietal layer only that contains pain-conducting fibres, while the visceral membrane may be handled with impunity. The abdominal organs also are not susceptible to painful stimuli, while even slight irritation of the parietal surface, such as that attending the introduction of laparotomy pads, is sufficient to produce severe suffering when operation is attempted under local anæsthesia. Even circulatory disturbances or a slight enteritis are sufficient to permit the escape of intestinal germs into the peritoneal lymphatics with a subsequent lymphangitis and possible peritonitis. The peritoneal inflammation is to be regarded as the reaction of the body to the infection. The greater the amount of fluid exudate the less the absorption and the greater the dilution of the toxins, but of greater importance is the early localization of the infected area by adhesions. In his operative technique the author introduces the innovation of making the incision through skin and aponeurosis under local anæsthesia aided by a hypodermic dose of morphine; the peritoneum is then opened under chloroform or ether and the necessary exploration performed, the anæsthetic being removed while a resection, intestinal suture, etc., is being done, and then resumed for the insertion of drainage and termination of the operation.

The Iodipin Reaction in Gastric Disease.—O. V. Peterson, in using this agent to test gastric motility, found that fuming nitric acid with chloroform gave the best reaction. Out of thirty-one persons, ranging in age from eleven to eighty-one years, and giving no gastric symptoms, it was found that in twenty-five the reaction appeared in twenty-five minutes, in eight in fifteen minutes, and in six between thirty and forty-five minutes. In a case of achylia gastrica the reaction appeared in fifteen minutes, in one of atony of the stomach in forty-five minutes, in the gastric crises of tabes in forty-five minutes, and in a case of ulcer only after one and a half hours. In eight cases of carcinoma the reaction was much delayed, not appearing till intervals of forty-five minutes to four and a half hours had elapsed. Control experiments with the stomach tube gave parallel results, the length of time required for the reaction to be obtainable corresponding closely to the degree of stenosis and retention.

Glioma of the Retina.—A. Petterson, on the basis of a histological examination of the tissues removed in three cases of this new growth, concludes that the theory of

Wintersteiner, that the tumor cells originate in the neuro-epithelial layer of the retina, is unnecessary, since it seems possible for the new cells to develop from the glia cells normally found in the ganglion cell and nerve-fibre layers in the manner formerly accepted as true.

Norsk Magazin for Laegevidenskaben, May, 1901.

A Case of Rupture of the Bladder.—J. Roll reports the case of a man who, while drunk, was pushed by a companion and fell heavily in the sitting position. Violent spasmodic abdominal pains followed, and he was brought to the hospital. Examination by palpation and by catheter failed to reveal a cause for the pains, the dysuria, etc., but a cystoscopic examination showed that there was a rupture about 3 cm. in length at the summit of the bladder. Laparotomy was performed and the wound sutured, and complete recovery followed.

Congenital Ichthyosis.—George A. Haus describes two cases of this affection. He believes it to be due to hereditary predisposition, and mentions its frequency in children of consanguineous marriages. He lays much stress on nervous taint, because of the close embryological relationship between the epidermis and the central nervous system.

Russki Arkhiv Patologii, etc., March and April, 1901.

Primary Epithelial Cancer of the Calices of the Kidney and Metaplasia of the Epithelium of the Mucosa of Calices, Pelvis, and Ureter.—D. P. Kichensky observed a rare case of cancer of the calices with a tendency to cornification and calcification. The right kidney and the liver were the seat of cancerous degeneration, and the diaphragm, peritonenm, and lymphatic ganglia were invaded. There was metastatic invasion of the lower part of the femur and of the knee joint. There was a rare form of degeneration of the mucosa of the urinary passages, consisting in a corneous degeueration of the epithelium of the mucosa, which appeared like epidermis, the subjacent layer having a singular growth of papillæ. In places the lumen of the urinary passages was blocked by cornefied masses. The walls of the calices, pelvis, and ureters beneath the mucosa were inflamed and infiltrated with round cells.

The Changes in the Cardiac Ganglia, the Heart Muscle, the Kidneys, and the Liver in Poisoning by Digitalis.—N. Klopotovski, from the result of experimentation on dogs, concludes that the changes in the cardiac ganglia consist in vacuolization and thinning of the protoplasm of the nerve cell, with shrinking of the cell body. At the same time there is chromatolysis of Nissl's corpuscles, with an accumnlation of fat droplets in the protoplasm and retraction of the nucleus. In the heart muscle there is simply intense hyperæmia with beginning fragmentation of the myocardium, and the disappearance of transverse striation in many of the fibrillæ. The liver and kidneys are even less affected, but in cases of intense poisoning there is albuminous and fatty degeneration, with pronounced pigmentation in the liver.

Intra-uterine Injections in the Treatment of Diseases of the Uterus and Appendages.—F. Bukoemsky is decidedly in favor of this form of treatment, and uses a solution composed of equal parts of tincture of iodine and alcohol with five per cent of alumnol, 1 to 2 gm. of the fluid being injected daily. Forty treatments usually bring about a cure. The best results are obtained in cases of acute gonorrhœal endometritis, in parenchymatous salpingo-oöphoritis, and in acute perimetritis. Small uterine myomata have been reduced in size, and the pains and metrorrhagia overcome. Salpingo-oöphoritis with cystic degeneration is not benefited by this treatment.

Analysis of the Blood in a Patient Suffering from Hæmophilia.—W. Zavialoff found that the erythrocytes contained cytoglobin, a body which, according to M. A. Schmidt, is not found in the red cells of normal blood. This substance possesses the property of preventing coagulation. Now, during the destruction of erythrocytes, which occurs when there is bleeding, the cytoglobin dissolves in the plasma and prevents coagulation. The blood flows from the vessel unchecked by coagulation. This is the explanation of the difficulty experienced in stopping the hemorrhages in cases of hæmophilia.

Iron in the Liver of Normal Man.—P. Bielfeld concludes that the amount of iron contained in the hepatic cells of healthy man is variable, the average being 0.169 per cent. of the pure, dried, hepatic cells. In women the amount is even less. In old age it is apparently increased. From the age of twenty to twenty-five years the amount is the least.

A Case of Pseudoleukæmia of the Skin.—S. K. Kirkaroff describes the histological lesions in a somewhat rare case of pseudoleukæmia with cutaneous localization.

Revue de Médecine, May 10, 1901.

Intermittent Nervous Disorders due to Malaria.—M. Busquet reports the case of a soldier in the Military Hospital of Marseilles, who suffered from intermittent paralysis of both anal and vesical sphincters, and of the right leg, these symptoms appearing only with febrile attacks, disappearing when the attack was over, and finally yielding to quinine. Hysteria, syphilis, and other infectious diseases were excluded. Malaria was preseut, as shown by the clinical symptoms and by blood examinations. It was, therefore, natural to infer that the paralysis was of malarial origin.

An Epidemic of Zona.—Charles Dopter reports an epidemic of this affection, a study of which leads him to the conclusion that its epidemic character is the expression of an elective affinity, either natural or acquired, of a special virus toward some one metamen of the central nervous axis, whose nourishment it interferes with. This may occur simultaneously or successively in several organisms. The infection alone, and not the ernption, is epidemic. Zona is merely a symptom, and as such can be neither contagious nor epidemic.

Polymyositis.—R. Lépine reports the case of a man whose symptoms were: (1) Pains and inflammation limited to certain muscles (left temporal and muscles of the forearm); (2) increase in size of the spleen. These are the chief symptoms of a disease known since 1887, to which Unverricht gave the name of dermatomyositis. The author prefers the name hemorrhagic polymyositis, or, if a distinction be necessary from the suppurative form, suggests angiomyositis as being correct and descriptive.

Archives Générales de Médecine, May, 1901.

Cerebro-Spinal Meningitis due to Influenza.—E. Sacquépée and E. Peltier report nine cases observed in Rennes in 1900. The diagnosis was supported by the result of lumbar puncture. Four of the patients are living and in perfect health, oue is still subject to cephalalgia and neuralgia, one has given no report. Three died. These results show that purely exudative meningitis may be completely cured; the purulent forms may be recovered from, or may leave some trace behind them. There is no specific treatment. The hypertoxic form defies all remedies. In the slower, more common cases, we may try injections of artificial serum, and administer antipyrin, sodium salicylate, or calomel internally. Lumbar puncture appears to be the most valuable form of intervention, and it is very probable that it acts by diminishing the pressure of the exudate, or by reducing the nnmber of infectious microbes.

Il Policlinico, May, 1901.

A Contribution to the Study of the Dysarthria and the Myasthenia due to Malaria.—L. Panichi reports the cases of two men suffering from dysarthria. The first had great difficulty in enunciating the letters R, S, Z, Y, and pronounced words very slowly, separating syllables by pauses. The second could scarcely enunciate certain linguals and dentals, especially N, R, and S. In both cases the cause of the trouble was found to be malarial infection. A third case was one of myasthenia; the voluntary movements of the arms were very slowly performed, and in certain positions there was tremulousness of the fingers. The muscles of the legs were flaccid, and the left foot was the seat of a rhythmical shaking every now and then. Active motions were slow. If the patient was put in a standing position, he very soon bent his knees and then fell. Quinine treatment cured all three cases.

Variations in the Figured Elements of the Blood in Malarial Fevers.—A. Dionisi, from the result of researches, concludes that during the febrile attacks of æstivo-autumnal fever and for some hours thereafter there is a marked oscillation in the number of red corpuscles and in the amount of hæmoglobin. In the ordinary tertian and quartan fevers there is very little change. The alteration in number of the figured elements in the small blood-vessels of the skin and in the veins during the fever is in relation not only to the variations in the calibre of the vessels and to the concentration of the blood, but also to disturbances of the capillary circulation in the internal organs which are characteristic of grave fevers.

The Discoveries of Professor Grassi in Malaria.—Ronald Ross absolutely contradicts the following assertions of Grassi: (1) That he exhibited one of Grassi's preparations at a London medical meeting. (2) That he asserted that he had succeeded in infecting people by the drinking of water. (3) That he asserted that his gray mosquitos transmitted tertian fever. (4) That he did not complete the cultivation of the human parasites in India because he was not able to do it. B. Grassi replies at length and still holds to his former conviction.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

PARLIAMENT—MR. BALFOUR ON RESEARCH AND ENGLAND'S LACK OF IMAGINATION—THE COLLEGES AND THE COUNCIL——PATHOLOGICAL SOCIETY — INTESTINAL INTOXICATION — PHARYNGEAL POUCHES—POSTERIOR VAGINAL CŒLIOTOMY.

LONDON, May 24, 1901.

THE War Secretary has stated his intention to appoint a committee of experts to report on the Royal Army Medical Corps in accordance with the recommendation of the South African hospitals commission. He appears to intend submitting his own proposals to that committee and to be taking time to prepare them. He declined to promise to obtain the report of that committee before the army medical vote comes on for discussion, on the plea that he could not fix the time such a committee would give to the duty imposed on it. The fact is the committee has not yet been formed.

The habitual drunkards bill gave rise to some unusually animated remarks in the House of Lords. The amendments made by the government in the committee stage have so transformed the bill that less than five lines of the original remain. This unusual course was pronounced inconvenient by Lords Spencer and Cross, but was defended by Lord Salisbury, who said he found it quite a convenient plan of dealing with the subject. He promised to make it a government measure in the lower House—so there is a prospect of some part of it passing into law. But with such extensive changes depending it may be premature to consider any part of it as secure, particularly as the cabinet is known to be very half-hearted in regard to all temperance reform.

Uncertified deaths, lead poisoning, and the manipulation of butter were also the subjects of questions in Parliament.

The Medical Graduates College and Polyclinic secured the leader of the House of Commons to preside at its dinner on Wednesday. Mr. Balfour was supported by a duke, a bishop, and a lord or two, so that the institution may be said to have established its position before the public, and certainly a considerable portion of the profession support it. Mr. Balfour spoke of it in three aspects—its consultations, as a charitable one, its educational work and research. The last subject is the one which attracts most attention, for while the need of more clinical or educational establishments is disputed, few are disposed to deny there is plenty of room for research. Mr. Balfour, with his turn for metaphysics, is yet a many-sided man, and often surprises us with his interest in subjects which seem outside his usual mental occupation. On the present occasion he startled some of his audience—not by mentioning some of the most striking developments of medical science in recent times, but by asking them, "in all solemnity and seriousness," whether this country had taken the lead which it should have done in that work? He told them he grieved to think that the richest country in Europe lagged behind Germany, France, and even Italy in equipping universities and colleges for research. He asked whether the country was too poor or too stupid, or did it lack only the imagination required to show what abstract studies might do for the happiness of mankind? He feared this country did lack somewhat of the higher form of imagination which recognized in studies showing no immediate direct results the foundation of knowledge far more conducive to happiness than material industrial advancement. Every discovery in a laboratory was the possession of the world, and they ought not to be backward in the great international competition which might help to balance to some extent the rivalry in producing destructive armaments. England would fail shamefully in duty if it allowed itself to be surpassed by every civilized nation in the competition.

The two Royal Colleges have taken another step in their defiance of the general medical council. Henceforth they will not require students to register. But suppose the council refuse to register qualifications granted on these terms. That would be the appropriate countermove. The mere announcement of such a determination would drive many students to other corporations, as they would not be prepared to enter on a lawsuit to compel the council to register them. The profession would support the council, knowing full well that the colleges in this, as throughout their history, are actuated only by selfish considerations. They want to attract candidates for their diplomas, and have always put the profits of the privilege of licensing before the welfare of the profession. The present trouble arises from this motive, and is a sort of competition with the other corporations for the fees charged for diplomas.

The annual meeting of the Pathological Society was held on Tuesday, when the officers, as proposed by the council, were elected for the ensuing year. Mr. Watson Cheyne is president again. The alterations in rules I have already mentioned were adopted, and the division into four sections is therefore established. The treasurer's report showed a satisfactory state of the funds.

A paper by Mr. Foulerton and Dr. Price Jones on "The Genus Streptothrix" was read. Cultures of twenty-five species were shown, of which ten were pathogenic. These included four new species, viz., streptothrix luteola, streptothrix lucea, streptothrix lucea saprophytica, and streptothrix erythrea. These species belonged to the higher fungi, as first stated by Hartz. Some other points were stated.

Dr. Sidney Martin communicated to the Medico-Chirurgical Society at the last meeting a case of intestinal intoxication which he thought due to appendicitis. The patient was a man aged fifty years, who had emaciated while troubled with loose, offensive evacuations from the bowels for some two months. Some lumps of apricots were passed which had been eaten eight weeks previously. The colon was flushed with boric solution without effect, and the man continued to waste, losing eleven pounds in fifteen days. The deep inguinal glands on the right side enlarged. A mass was felt in the right loin. Abdominal exploration showed this mass to be the kidney, made palpable by the extreme emaciation. The cæcum was thickened, the appendix thickened and elongated, and there were some calcareous glands between the ileum and cæcum. These, with one other enlarged gland, were removed, as well as the appendix, the contents of which were so extremely fetid that it had to be removed from the room at once. Two small erosions of the mucous membrane and enormous thickening of all the coats of the appendix were the chief changes, and to these was attributed the origin of the disease. The patient slowly recovered. In this case it is noteworthy that the main symptom was decomposition of the intestinal contents, causing profound general intoxication, such as is seen in dysentery or colitis. No bacteria were found in the walls of the appendix or in the thickened gland. The enlarged glands on the right side disappeared after the operation.

Mr. Godlee said enlargement of the inguinal glands in association with appendicitis was new to him. Mr. Symonds suggested that the case was really one of colitis involving the appendix, and would have recovered without operation. The four symptoms—looseness, fetid fæces, irregular temperature, and deep emaciation—formed the clinical picture of ulcerative colitis. He had had a patient who had recovered from five successive attacks, these four symptoms being present in all. He doubted if any form of appendicitis would explain the case. Mr. Morgan, who knew the patient well, said that shortly before the illness there was no looseness. The cause of the enlarged glands was uncertain—perhaps it was due to the decomposing matter in the appendix, which also gave rise to the general infection. Dr. Martin replied, after which a detailed account of a case of a large pharyngeal pouch, removed by operation, was given by Mr. Godlee and T. R. H. Bucknall. When first seen, the swelling looked like an enlarged gland on the left side of the neck, at the level of the hyoid bone in front of the sterno-mastoid, but it was soft, and on percussion gave a tympanitic note. It was attached to the top of the larynx, following its movements. A squeaking sound was produced by squeezing it, and an unpleasant sensation which lasted for days. The pressure caused an obvious diminution in size. The operation, which was not without some difficulties, was fully described. Reference was made to the literature of pharyngeal pouches and fistulæ, of which some two hundred cases have been recorded. It seems probable they all arise in connection with one of the visceral clefts, the varieties depending on the position of the obliteration of the cleft. The relation of the nerves and vessels is of the greatest importance, but is not so perfectly ascertained as is desirable. The relation, for instance, of the carotids has been differently described. The necessity for careful dissection is accordingly obvious.

Dr. William Alexander, of Liverpool, has communicated to the Gynæcological Society an interesting account of his experience in posterior vaginal cœliotomy in operations for pelvic disease. In the last two years he resorted to this procedure in ninety-four cases. These did not include hysterectomies for cancer or for removal of fibroids or other diseases when Douglas' pouch was opened as a small part of an extensive operation—nor abscesses pointing into the vagina and sinuses opening into it, but only cases in which the pouch was opened as the route for the removal of disease. Among the cases were two of hydrosalpinx, four of pelvic cellulitis, fourteen of pyosalpinx, twenty-two of ovarian cysts, seven of pelvic hæmatocele, and other serious conditions. But he lost only two of the cases. One patient was carried off by pleuro-pneumonia, which set in on the evening of the day of operation; the abdomen was not affected. The other case was one of a small abscess in the

ovary, and he was tempted to try and save the organ, but streptococcus infection set in the same evening and rapidly spread to the general peritoneal cavity. In all similar cases he had previously removed the suppurating movable structure, and said he would take good care to do so in future.

With this success, Dr. Alexander disclaimed being an advocate of the vaginal in preference to the abdominal route. In fact, he said he had performed two hundred and four abdominal operations in the same two years out of a total of fifteen hundred and sixty-seven operations of all kinds. Nevertheless, he admitted being much impressed with the ease, safety, and short duration of the vaginal operation, as well as the comfortable and rapid convalescence of the patients.

Lieutenant-Colonel Babtie, V.C., has been appointed temporary assistant director of the army medical department.

Surgeon-General Jameson, C.B., will retire from the director-generalship of the army medical department on June 1st. In future this office will be held for a term of only five years.

Deputy Surgeon-General Fyffe, M.D., died on the 17th inst., aged seventy-five years, and Deputy Inspector-General Finucane on the 15th, aged seventy-three.

ASEPSIS AND AMBULANCE SURGERY.

To the Editor of the Medical Record.

Sir: It is a recognized principle in surgical practice, that a wound should be treated by clean hands and clean instruments in a clean place.

This principle is known and followed quite generally from great cities to rustic hamlets. In the war with Spain, our hospital corps and our soldiers were instructed to put on a clean dressing at once, and bring the wounded as soon as possible where they could be treated in a clean place by clean instruments in clean hands. The result of this immediate dressing of wounds with subsequent "clean" treatment was eminently satisfactory—many a seemingly mortal wound healed kindly because of that first dressing. Now that this surgical axiom has reached the uttermost parts of the earth, is it not about time for it to reach our New York ambulance surgeons?

To-day the ambulance surgeon, intent on his "diagnosis," primarily ignores the first principle of surgery—cleanliness.

Every wound, especially if it involve brain, joint, or peritoneum, must be carefully and thoroughly explored by "that dirty finger"—explored until that ambulance surgeon, with his "totus in illis" expression, is sure that the wound does or does not involve the deeper structures—then his case, made septic by his careful examination, is aseptically bandaged and rushed to the hospital, where the "diagnosis-crazy" surgeon reports "incised wound, involving the right knee joint."

It is time to stop at once and forever such treatment. To-day a physician receives a hurry call to an injured man. He finds a clean cut wound, evidently involving the knee joint; he quickly applies an aseptic dressing, while the policeman orders the ambulance, which brings that "diagnosis-crazy" surgeon.

At once that dressing must be cut off, and that dirty finger must at once explore every nook and corner, while the patient looks on in agony, and the medical men with disgust. It is time to cry a halt to such treatment in this city of surgical progress—it is time for New York hospitals to instruct their ambulance surgeons to keep their unclean fingers out of severe wounds.

R. Ellis, M.D.

211 West Thirty-fourth Street, New York.

The Value of Aluminum Bronze Wire in Surgery.—R. Pichler ascribes to this material greater usefulness and adaptability for surgical purposes than has silver. By actual experiment it was found that it possessed greater inhibiting powers on the growth of bacteria than the latter metal, and it seems especially adapted for use in situations where infection of the suture wounds is to be feared, as in the perineum, inguinal region, and the mouth, as well as where the sutured tissues are under great tension, and the stitches are to remain in place for a considerable length of time.—*Centralblatt für Chirurgie*, April 20, 1901.

Surgical Suggestions.

Salt Solutions.—

Sodium sulphat	10
Sodium chlorid	5
Aq. destil	1,000

—Hayem.

Sod. hyposulphit	gr. xlv.
Sod. carbonat.,	
Sod. chlorid	āā 3 i.
Aq.	Oij.

—W. W. Johnson.

Sod. chlorid	5.
Sod. hydrat	1.
Sod. sulphat	2.5
Aq.	1,000.

—Durantz.

In pneumonia:

Sod. chlorid	1.
Sod. bicarb	0.5
Aq. destil	100.

—Pellegrene.

Salt solution, even when given by subcutaneous infusion, is only secondarily a cardiac stimulant. If used hot, the direct cardiac stimulation of the heart will often be more than offset by the depression resulting from increased excretion. Heat beyond body temperature is of doubtful value, and may actually oppose the action of the saline solution. In most cases the physiological salt solution, to secure the best results, should be used conjointly with an approved heart stimulant. The heart stimulant may be supplied by adding alcohol to the solution to be infused.

Thousands of experiments upon human beings and upon animals by hundreds of experimenters have proven most conclusively that for efficiency, freedom from danger, and ease of administration the subcutaneous injection of decinormal salt solution (hypodermoclysis), six drachms of sterilized salt to one gallon sterilized water, at a temperature of from 100° to 120° F., excels any and all things that have ever been used to relieve those suffering from shock from the effects of hemorrhage, and as an eliminant in septic and toxic conditions.—J. K. Eastman, in *The Medical and Surgical Monitor*, March 15th.

Interrupted Ether Narcosis.—Kronacher believes that most of the unpleasant after-effects of ether anæsthesia are due to the amount of drug employed and the length of time the patient is kept unconscious. Major anæsthesia is usually employed for many small operations which do not really demand it, and the author describes a method which makes painless operating possible with a minimum amount of the anæsthetic. One or two drachms of ether are poured into the inhaler and several deep breaths taken. The same quantity of ether is again added and the anæsthetization continued till the stage of excitement begins. The operation in most cases can now be done without any further administration of anæsthetic, though rarely a third addition of 3 ii.–iii. is necessary. The duration of such a narcosis is about ten minutes, and while the patients are not unconscious and often cry out, all memory of pain is effaced on awaking. This method obviates ether pneumonias and does away with the usual headache and nausea.

Preparations and After-Care.—The patient should be prepared at least four days before operation. Prolonged preparations on the table, exposure of large areas, and prolonged anæsthesia are condemned. Handling the intestines unnecessarily, introduction of dry gauze into the abdominal cavity, increase the chance for complication, especially flatulency. Special

attention should be paid to the temperature of the operating-room at the time of the operation, and the body temperature should be carefully looked after by the application of heat during the operation. Saline solution for hypodermoclysis should always be ready and employed freely when there is any considerable loss of blood or shock. Every operation should be performed as rapidly as is compatible with careful surgery. Rubber gloves should be worn by operator, assistants, and nurses in every operation. Morphine and atropine should be given whenever the pain is intense. Reaction when delayed should be hastened by saline injections, heat, and strychnine. Sepsis and exhaustion are to be combated by strychnine, saline solution, and whiskey. Preliminary administration of nitrous oxide gas followed by ether is recommended. —Rogers, *St. Paul Medical Journal*, March.

Curetting the Urethra.—Irrigate with 1 : 40,000 bichloride solution. Instil a four-per-cent. cocaine solution. Introduce a large endoscopic tube and localize the diseased area (posterior urethritis). Curette, removing all diseased tissue; apply a ten-per-cent. nitrate-of-silver solution. — George Walker, *Maryland Medical Journal*, March.

Gloves or No Gloves.—I cannot imagine a young operator becoming very expert if he uses gloves. I believe that more bacteria drop into the long exposed wound of the glove operator than are carried in by well-prepared bare hands.—Robert T. Morris.

I believe that if a man cannot keep his hands clean, he cannot keep gloves clean.—John B. Murphy.

I have never had a pair on; I do not recommend them.—Joseph Price.

In Europe, where experiments were first made with different materials for covering the hands in operating, gloves are employed less than formerly. The Berlin surgeons rarely use them, and Tuffier is said to be the only glove operator in Paris.—H. A. Royster.

Ethyl-Chloride Anæsthesia.—The advantages of ethyl chloride are the rapidity with which anæsthesia is produced and recovered from, the lessened vomiting, and the absence of injurious renal irritation. Even prolonged anæsthesia in many cases in which there were cardiac or pulmonary complications was not followed by bad results. A death which occurred about three minutes after the beginning of the anæsthesia is reported. The man was an alcoholic; great excitement occurred, whereupon more ethyl chloride was poured into the mask. Cyanosis appeared, and was followed by death. The latter was attributed to asphyxia.—Lotheissen.

Therapeutic Hints.

Influenza in Infants. — We have no drug that affects the course in the least, and much harm is done by trying to do too much with drugs, especially with the coal-tar antipyretics. Quinine in full doses is alone of definite value.—Zohorsky, *St. Louis Courier of Medicine*, February.

Useful Items.—Calomel in doses of gr. $\frac{1}{10}$, combined with a little white sugar, is a very valuable remedy in chronic diarrhœa. Calomel is one of the best of gastro-intestinal sedatives.—The bisulphide of carbon poured on cotton in an open-mouthed bottle and held against the forehead will, it is said, promptly relieve nervous headache.—The addition of a small amount of white sugar greatly increases the solubility of borax.—Wine of colchicum in doses of ♏ v.–x. is useful in obstinate sciatica.—Slippery elm, infused in hot water, is excellent in throat diseases. It is especially valuable in obstinate cases of ptyalism, met with sometimes in the pregnant condition.—Obstinate epistaxis is often benefited by having the patient soak the hands and feet in water as hot as can be borne.—Ergotol for hypodermic injections is preferable to ergotin. In a recent case of hemorrhage from the bowels in typhoid fever it acted promptly and well. Two injections were given of ♏ xx.—F. W. Campbell.

The Treatment of Anthrax.—In man, says Salvatore Gugliuzzo, the most common manifestation of anthrax is malignant pustule, introduced into some small cutaneous lesion, or taken in with the flesh of some animal that has died of the disease. Treatment is usually efficacious, whether it be cauterization with the Paquelin cautery, the use of Sclavo's serum, or injections of phenic acid and bichloride of mercury, so that the prognosis is good.—*La Riforma Medica*, May 7th.

The Treatment of Malignant Growths by Coley's Fluid.—Robert B. Wild summarizes the effects of this treatment in eight cases as follows: Pain was severe in two cases only. Local reaction, in the form and redness and swelling, occurred in three cases. General reaction, in the form of a rise of temperature with or without rigors, was absent in two cases, slight in three cases, and marked in three cases. The dose required to produce a general reaction varied widely with different patients; in one case ♏ i. was followed by a temperature of 103° F., while in another case ♏ xvi. failed to cause any marked rise. In several cases the effects appeared to be cumulative. In one case little effect was produced by a dose of ♏ v., until fourteen injections had been given, when a rigor and rise of temperature suddenly occurred. The patients' appetite and nutrition were not impaired, and the patients did not lose weight more rapidly than usual in similar cases. One patient gained weight. In four cases there was no effect upon the disease, which steadily progressed, and ended fatally in about the usual time for similar cases in the hospital; certainly no harm resulted from the treatment. In two cases the effects of the injections appeared to be unfavorable, and in feeble patients the writer thinks it is not advisable to employ this method of treatment at all. In two cases, the patients themselves considered the treatment to have been beneficial, and certainly lived longer than ordinary, considering the extent of the disease. Both, however, died within twelve months, and any benefit from the treatment must have been only of a very temporary nature. The writer does not consider that the results so far justify the trial of Coley's method in any operable cases of malignant disease, whether carcinomatous or sarcomatous. A recourse to it only wastes valuable time, and may render subsequent successful operation impossible. In cases of inoperable carcinoma and epithelioma, there is no evidence of any permanent benefit, and the treatment is by no means free from danger. In the absence of any other means of effective treatment, a careful trial of Coley's fluid is justifiable in cases of inoperable sarcoma, especially the more rapidly growing forms. A limited number of successful cases have been reported in which the disease was of this type, and other cases in which there was a temporary improvement. It appears by no means certain that the effects produced by the toxins are identical with those which result from an attack of genuine erysipelas, and further researches upon the after-effects produced by erysipelas are desirable.—*The Medical Chronicle*, March, 1901.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-second Annual Meeting, Held in St. Paul, Minn., on June 4, 5, 6, and 7, 1901.

(Concluded from page 930.)

SECTION ON PRACTICE OF MEDICINE.

Third Day—Thursday, June 6th.

Modified Treatment of Typhoid Fever.—Dr. T. B. Greenley, of Meadow Lawn, Tenn., advocated the use of acetanilid with quinine, which, he claimed, had a soothing and quieting effect, and prevented the possibly irritating effects of the latter. He had never observed any depressing effects of the drug upon the heart. The dose was increased or diminished according to the rise or fall of the temperature.

Medical Shock.—Dr. O. T. Osborne, of New Haven, did not wish to advocate the use of the term medical shock for conditions of failing heart due to distinct pathological conditions, or due to a gradual break-up in the system by very acute or prolonged intense processes; he thought the term was justifiable when a badly acting and gradually weakening heart was the most urgent cause for anxiety, and its weakness was out of proportion to the pathological conditions or symptoms present. He believed that we were justified in using the term medical shock as we were in using the term surgical shock. The symptoms of this were a more or less rapid heart; irregular, perhaps dicrotic, or intermittent pulse; incomplete inspirations without much actual dyspnœa, interspersed with frequent sighs; and the subjective symptoms of precordial oppression. The temperature was generally low, the flesh cool and clammy, and if quick relief was not obtained death would soon take place by heart failure or medical shock. He believed that medical shock was just as certainly a vasomotor paralysis as was surgical shock, and, as a consequence, the major part of the blood was to be found in the abdominal veins. The blood flowed slowly into the dilated and therefore non-elastic arterioles, hence slowly into the capillaries, and returning slowly in the veins imperfectly filled the heart cavities. The heart contracted irregularly, incompletely, and arrhythmically. The aorta had not the pressure ahead or the forcible quota of blood from behind, and consequently did not give enough elastic rebound to force the blood properly into the coronary arteries, and the heart muscle was improperly nourished. By the lowered blood pressure all the functions of the body began to fail, all digestive processes were impaired, and molecular death began to take place; at last almost unaccountably gradual failure of body and mind occurred until death closed the scene. Severe acute nerve pain would, if continued, give a lowered vasomotor tension, and if too long continued or too severe, vasomotor paralysis or shock, perfectly similar to that due to profound injuries of these nerves, or surgical shock. In acute feverish processes our aim should be to make the elimination at least equal to the production of decomposing and fermenting products and to prevent the absorption of these products if possible. In all diseases or conditions in which absorbed poisons existed, as in typhoid fever, dysenteric ulcers, pus collections, malarial plasmodia, hæmoglobin débris, cancerous disintegration, unhealthy mucous membranes, etc., any treatment which hastened the evacuation of the excreted bile impregnated with toxins would prevent systemic and nervous poisoning and ultimately vasomotor disturbances and medical shock.

Coughing a Means of Disseminating Tubercle Bacilli; a Study of Fifty Cases.—Dr. L. Napoleon Boston, of Philadelphia, said the conditions which prompted him to investigate the degree with which tubercle bacilli were disseminated by coughing were, first, that he noticed that fine droplets of sputum were ejected with each act of coughing, and second, that coughing was often excited by eating. He thought that this was a potent factor in the dissemination of tuberculosis, and possibly explained why patients in the early stages of tuberculosis did badly in institutions where every attention was given to ventilation, light, and the disinfection of sputa. The spray was collected by a mask, the essential features of which were that it was made from German-silver wire, one piece of which was moulded to fit the face. Suspended from this was a second oblong portion provided with two lateral grooves, which served to receive two microscopic slides. When the mask was in position the slides were held directly in front of the mouth and nose at a point three inches from the lips. Patients wore the mask with clean slides from one to one and a half hours, and were instructed to remove it during paroxysms of coughing. Of the fifty specimens obtained from fifty patients, thirty-eight were found to contain tubercle bacilli in variable numbers, four to six being the smallest found in any specimen. Of the twelve negative cases explanations were given. In three of these the patients were so very weak they did not talk while wearing the mask. It was shown that the secretions of the mouth and respiratory tract were atomized and given off in the form of spray, in both health and disease, and that this spray contained bacteria and other cellular elements known to be common to such secretions, and therefore it was reasonable to suppose that many other diseases were conveyed by this medium, and that the work accomplished through the study of consumptives was but a step in a direction which bade fair to modify the hygiene of infection. Conditions affecting these organs and consequently their secretions must of necessity be spread in this way; especially was this true of diphtheria, tonsillitis, and possibly smallpox, measles, scarlet fever, whooping-cough, mumps, etc. Droplets alighting on clothing must serve as a favorable means to convey the disease from house to house; and that men might become infected by the spray projected by horses, cows, and other domestic animals suffering from glanders, tuberculosis, and similar affections, appeared to be highly probable.

The Value of Throat Cultures in Diphtheria.—Dr. M. H. Fussell, of Philadelphia, said that the following statements could be proven: (1) True cases of diphtheria might have few or no clinical symptoms. (1) Cases of tonsillitis or pharyngitis might have severe symptoms and be serious, but true diphtheria not being present, the disease not being due to the Klebs-Loeffler bacilli, they were consequently not able to transmit diphtheria. (3) A diphtheritic exudate might be easily detached and leave no bleeding surface. (4) An exudate due to some other organism might be a true membrane impossible to detach from the mucous membrane. He said that cultures could most surely and with less risk of mistake be made in the laboratories, but they could be made at home and should be made there if we intended to keep pace with the rapid strides of recent medicine.

Genito-Urinary Examination by the General Practitioner; with Demonstrations on Patient.—Dr. Ferd. C. Valentine, of New York, made practical demonstrations upon patients to show that (1) all genito-urinary examinations should be painless; (2) the operator should conduct no examinations unless his arms were bared to above the elbows and his clothing protected by a gown and apron; (3) during every gen-

ito-urinary examination, the physician should protect his eyes with spectacles (not eye-glasses) even if he had no visual defect; (4) ideal examinations were made in the morning, before the patient had passed his urine; (5) the amount and character of a urethral discharge could be estimated only by correct technique in expressing the urethral contents; (6) the color of the urethral discharge changed when it dried upon the patient's garments; (7) the meatus should be cleaned before urine was passed for examination; (8) the manner of urinating was often pathognomonic; (9) the epithelium found in the urine was indicative of the locality of the lesion; (10) examination of the urethral adnexa was a necessary part of the steps for complete diagnosis; (11) no instrumental ingression of the urethra should be attempted without most thorough efforts at rendering it aseptic; (12) the technique of urethral asepsis was neither complicated nor difficult; (13) the soft bougie-à-boule was the only instrument that could be used for tactile exploration of the urethra; it was a purely diagnostic instrument; the rigid sound was wholly a therapeutic instrument; (14) urethroscopy with a modern instrument was not difficult; (15) the general practitioner was perfectly competent to examine the vast majority of genito-urinary cases; (16) such examinations only exceptionally required extraordinary skill or a large armamentarium; (17) the pathology of genito-urinary diseases in no wise differed from that of other affections.

Clinical Observations on Pericarditis.—Dr. Frank Billings, of Chicago, stated that pericarditis was essentially a secondary process occurring in the course of some general infection. The local manifestations might be so slight as to escape observation, and the general symptoms to which the local disease might give rise might be obscured by the constitutional disturbance of the primary general infections. Therefore it often happened that the diagnosis of pericarditis was more often made at autopsy than clinically. The histories of several cases were given which illustrated pericarditis of several varieties etiologically considered, which presented clinically, as far as the heart and pericardium were concerned, practically the same signs and symptoms. The cases further illustrated the importance of the three cardinal signs of pericarditis; namely, the pericardial friction rub, the form or outline of precordial dulness, and the position of the apex beat, especially in relation to the left border of precordial dulness. The pericardial friction rub was doubtless present in every case of pericarditis in some period of its course. It was practically the sole local sign in plastic pericarditis. It might not be recognized in pericarditis with effusion, although it was probably present in every case at an early stage of the disease and in cases of recovery after the disappearance of the effusion; it might be present too during the stage of effusion. The form of this outline of dulness in pericardial effusion was also characteristic. The pear-shaped outline with the base downward; the dulness, even in the early stage of effusion, in the fifth right interspace close to the sternum, obliterating the resonant angle formed by the lung, heart, and liver; the dulness over the sternum extending to or above the second rib, together with the outline of the left border dulness, were easily recognized and were almost pathognomonic. It was also true that a greatly enlarged heart with all the chambers dilated from myocarditis and a weak, diffusible apex beat might present an outline of dulness which so nearly resembled that of pericarditis with effusion that it might be impossible to differentiate between them without puncture. The location of the apex beat in pericarditis with effusion was characteristic. When it was perceptible it would always be found that the left border of dulness was relatively far removed from it as it was not in any other cardiac disease. In large effusions it might be obscured, and at other times the right ventricle might strike the chest wall in the region of the nipple, or undulatory waves might be seen as the only evidence of the heart beat against the chest wall. However, it did not matter how the apex beat or the impulse of some other part of the heart against the chest wall be ascertained; it would be found that the point of contact of the heart against the chest wall was always relatively far removed from the left border of precordial dulness as compared with the relations of the apex beat to the left border dulness in all other conditions. The relatively rapid respiration and dyspnœa, the signs of compression of the left lung evinced by the left subscapular dulness and bronchial breathing, the rapid heart action, the pulsus paradoxus, and the asymmetry in size of the pulse of the radials, the irregular type of temperature, the paralysis of the left recurrent laryngeal nerve, the unequal pupils, the disturbed mental state of the patient, and still other phenomena were signs and symptoms not so characteristic as the three cardinal signs first named, but were important and significant when present. Pericarditis was an easily recognized condition. Frequent careful systematic examination of the precordium should be made in all infectious diseases, and if this was done pericarditis would not escape the examiner.

Pathology and Pathogenesis of Pericarditis.—Dr. Joseph McFarland, of Philadelphia, had found pericarditis more frequent in men than in women, probably because the former were more exposed to its causes. Concerning the relative frequency authors varied. It was customary to divide the cases into those which were primary or idiopathic and those which were secondary or metastatic. Traumatism as a cause of pericarditis was of importance only as it afforded an avenue of entrance for micro-organisms, or produced conditions favorable to their colonization in the tissues. Lymphogenous metastasis might occur in many of the local affections in which no actual traumatic lesions existed. In this manner disease of the mediastinum, pleura, etc., might occasion pericarditis. Hæmatogenous metastasis was seen in nearly all of the infectious diseases, but especially in rheumatism, pyæmia, septicæmia, pneumonia, chorea, scarlatina, etc. There was no specific micro-organism of pericarditis. Breitung collected 324 cases of pericarditis among the autopsies of the Berlin Charité during ten years, and found them distributed as follows: Pericarditis serofibrinosa, 108; hæmorrhagica, 30; purulenta, 24; tuberculosa deuteropathica, 24; tuberculosa idiopathica, 2; adhæsiva partialis, 111; adhæsiva totalis, 23; ossificans, 2. It was an error to think of these names as referring to distinct forms of the disease; they were for the most part stages of the same process. In 39 cases studied by Louis the exudates were serous 9 times; purulent, 7; serosanguinolent, 10; seropurulent, 13.

The effect of pericarditis upon the heart was of great importance; no considerable disease of the epicardium was possible without involvement of the heart. The superficial layers of muscular fibres usually showed cloudy swelling, later hyaline or fatty degeneration. In purulent exudate the pus might also gradually work its way between the muscular bundles. The changes that thus took place during the height of the disease predisposed to acute dilatation of the heart, and a fatal termination of the disease might thus be brought about. If this did not occur, and if the patient recovered from the pericarditis, the regenerative cicatricial processes that went on led to fibroid interstitial changes in the wall of the heart.

The General Etiology of Pericarditis.—By Dr. Robert B. Preble, of Chicago. He drew the follow-

ing conclusions: "1. Cases of acute pericarditis, which are clinically primary, may occur, but are rare. 2. Diseases in which pericarditis appears as a complication are: Pneumonia, 34; rheumatism, 23.36; chronic diffuse nephritis, 11.2; tuberculosis, 10; sepsis, 4.7; aneurism, 2.6; typhoid, 1.7 per cent. 3. The more extensive a pneumonia, the greater the danger of this complication. 4. The danger is somewhat greater in left than in right-sided pneumonia. 5. When only one lobe is involved, the danger is least in pneumonia of the right upper lobe and greatest in a right middle or left upper lobe. 6. The chances of pericarditis in unilobar pneumonia are one in forty; in bilobar or trilobar, one in ten; in quadrilobar, one in five; and in pneumonia of the entire left lung, one in eight. 7. The mortality of pneumonia with pericarditis is 92.4 per cent. 8. Rheumatic pericarditis is complicated by endocarditis in 60 per cent. of the cases, *i.e.*, three to four times the normal rate of cases of endocarditis. 9. The danger of pericarditis complicating rheumatism is the greater, the younger the individual, and is somewhat greater in males than in females. 10. In acute pericarditis the site and extent of the endocarditis is apparently of no importance. 11. Pericarditis appears as a complication of all forms of nephritis, but particularly chronic diffuse nephritis with contraction. 12. It is extremely ominous: 84.6 per cent. of the patients died. 13. It is still uncertain whether the pericarditis is toxic or infectious. 14. Tuberculosis excites only one-tenth of the cases, and when one considers the extreme frequency of tuberculosis, pericarditis must be regarded as a rare complication. 15. Pericarditis may be a part of a generalized acute tuberculosis, but is more often the result of a chronic tuberculosis of the lungs or mediastinal glands. 16. Septicæmia and pyæmia contribute a very considerable number of cases of pericarditis. The primary focus may be remote or close to the pericardium. 17. Aneurism of the aorta causes 2.6 per cent. of all the cases, a very high figure when one recalls the comparative infrequency of aneurism. 18. Typhoid fever, which is rarely complicated by inflammation of the serous membranes, other than the peritoneum, contributed 1.7 per cent. 19. Obliteration of the pericardium is due to endocarditis, tuberculosis, chronic nephritis, aneurism. 20. Relatively six times as many cases of obliteration of the pericardium occur with aortic and mitral endocarditis than with either lesion singly. 21. Tuberculosis causes but few cases of obliterative pericarditis. 22. Pericarditis, accompanying nephritis, is not always fatal, but may apparently end in the formation of adhesions."

Adherent Pericardium.—Dr. Robert H. Babcock, of Chicago, stated that adherent pericardium was encountered in two forms—first, that in which adhesions between the two layers of the sac occurred, but not of the pericardium to the surrounding parts, pericarditis interna; and second, the pericardium adherent to the epicardium and also to the neighboring structures, pericarditis interna et externa. He then considered the effects on the heart and general circulation, with special consideration of its effect on the liver, leading to the so-called pseudo-atrophic cirrhoses of the liver. Diagnosis, in the first form mentioned, was usually very difficult and often impossible. If the adhesions were limited to the two layers of the sac, and if they were unassociated with valvular disease, the result might be only hypertrophy of the heart, and the circulation would be carried on adequately and no subjective symptoms were produced. If pericarditis led to adhesions while the heart was in dilatation from endocarditis, then the heart was prevented from ultimately returning to its previous size and the symptoms were likely to occur, viz., those due to stasis. In the second form mentioned the diagnosis was often easy in consequence of the signs resulting from the pulling of the adhesions upon the surrounding soft parts.

Tuberculous Pericarditis.—Dr. C. F. McGahan, of Aiken, S. C., stated that this form was much more prevalent than had heretofore been generally accepted. He believed that a great many obscure heart troubles in the anæmic, in which we could find no valvular disease, occurring without marked symptoms of pericarditis, but in which we had certain marked symptoms of the disease, were due to tuberculous pericarditis, particularly if the patient subsequently began to lose weight and to assume a cachectic appearance. This condition usually progressed insidiously. The symptoms were those of enlarged heart, or of adherent heart, together with the general symptoms of malaise and more disturbance of the entire system than would be found in simple pericarditis, or that secondary to rheumatism, or one of the exanthemata.

Cardiac Lesions as Observed in the Negro; with Special Reference to Pericarditis.—Dr. Frank A. Jones, of Memphis, Tenn., stated that aortic regurgitation in the negro was the most frequent and most dangerous of all valvular lesions. The next most frequent was aortic stenosis, and then mitral regurgitation. Mitral stenosis had not been diagnosticated, in the cases he reported, from the physical signs and symptoms. Tuberculosis and syphilis acted both as exciting and predisposing causes in the production of muscular and valvular lesions. A syphilitic history was more frequently found in mitral regurgitation than was one of rheumatism. The murmur of aortic regurgitation was most frequently musical.

Some Points on the Treatment of Pericarditis.—Dr. Frank Parsons Norbury, of Jacksonville, Ill., said that it behooved us, in the treatment of rheumatism, acute infectious fevers, and septic processes, to keep ever in mind the possibility of pericarditis as an aftermath, and govern ourselves accordingly by insisting upon absolute rest until this danger was past. Milk should be given in small quantities every two or three hours. Most cases of rheumatic pericarditis got well, if left alone. For the relief of pain, a blister over the pericardium would often be sufficient, or cold applications, or an ice-bag. When other means failed, morphine should be given, being guarded with proper cardiac support; for the restlessness, bromide of sodium, usually about noon, again at four or six, and at bedtime. For the cardiac distress, strychnine might be given, or, if necessary, digitalis with strophanthus. If the effusion was moderate and not septic, it would be absorbed, and even if large the chances were that, with cautious use of diuretics and purgatives, it would disappear. The indications for surgical interference were, according to Osler, "dyspnœa, small, rapid pulse, dusky, anxious countenance," and, the writer added, "physical signs of extensive effusion."

SECTION ON SURGERY AND ANATOMY.

Third Day—Thursday, June 6th.

Hæmostasis and Amputation at the Hip-Joint: A Résumé of Two Hundred and Six Cases by the Author's Method.—Dr. John E. Wyeth, of New York, read this paper. It was not generally known, he stated, that his method of hip amputation was suggested to him by a series of experiments which he made on the shoulder joint. In 1890 his technique was published. At that time the mortality was sixty-four per cent. The two hundred and sixty-seven cases reported, he had divided into three groups: (1) Neoplasms; (2) septic infections; (3) injuries. In the last, the mortality was 63.9 per cent., but this was to be explained by the fact that the trauma and the shock sustained by these cases rather than any operative intervention

were the cause of death. If in every case of grave injury calling for hip amputation a preliminary venous infusion was practised, this mortality would probably be much reduced. In 1881 the death rate was sixty-four per cent.; it was now but 19.8 per cent.

Dr. Walker, of Detroit, reported four new successful cases.

Dr. Wyeth, in closing, said that the pins gave the surgeon a sense of security afforded by no other technique, and there was no case on record in which they had been baneful.

Autoplastic Suture in Hernia and Other Ventral Wounds.—Dr. L. L. McArthur, of Chicago, read this paper. Ribbons of tissue six inches long were cut from each margin of the wound of the external oblique, and were left attached below. They did not remain flat; they possessed a tensile strength of from seventeen to twenty pounds. The technique of their introduction was to tie a fine bit of silk threaded on a needle to the end of the ribbon and sew the wound in continuous suture. In the seventeen cases in which this had been done, the results had been perfect; there had been no post-operative pyrexia, and while as yet enough time had not elapsed to make a definite statement, it appeared that the method had merit.

A New Method of Skiagraphic Diagnosis for Renal and Ureteral Surgery.—Dr. L. E. Schmidt and Dr. G. K. Olischer, of Chicago, presented this paper. Their technique had been perfected through the use of a lead-antimony wire, which they introduced into the ureters. This alloy was extremely soft and flexible and cast a very dense shadow. Some of its advantages were: (1) Freedom from danger. (2) Diagnosis of dilated pelves, calculi, and other obstructions. (3) Differentiation of hepatic from renal stones. (4) Differentiation of non-renal neoplasms from dislocated kidney. (5) It gave the course of the ureters.

Prostatotomy vs. Prostatectomy for Prostatic Hypertrophy.—Dr. Ramon Guitéras, of New York, read this paper. It consisted largely of a classical presentation of the development of these operations. He outlined the method which had given him the greatest satisfaction. By placing two fingers high in the rectum, he was enabled to steady the gland and rapidly enucleate it with the other hand. This condition, until recently so neglected, was too grave a one to allow of dogmatism. Of the younger patients, from sixty to seventy years of age, most should undergo the radical operation. Physiologically old cases often must be given Bottini's treatment. A third class existed which could tolerate no surgical intervention. So far the mortality of prostatectomy exceeded that of prostatotomy threefold.

Prostatotomy 753 Cases.			Prostatectomy 152 Cases.		
Cures.	Deaths.	Failures.	Cures (successes, recoveries).	Deaths.	Failures.
622 86 per cent.	44 5⅞ per cent.	87 11 per cent.	121 79 per cent.	25 16½ per cent.	6 3 per cent.

Prostatectomy the Method of Choice in the Management of Prostatic Obstructions.—Dr. Eugene Fuller, of New York, presented this paper. He began with a plea for the radical operation. The general practitioner knew as little about the indications for operation in these cases as he knew of appendicitis twelve years ago. The question of age, which was usually brought forward as the main argument against the radical operation, was shown to have but little significance. Under proper surgical conditions the mortality of prostatectomy in average cases was not over eight per cent. or ten per cent; not over twenty-five per cent. even in the most desperate conditions. A strong argument in favor of the radical operation was that patients who died were at rest; those who recovered were cured. The Bottini method was at best applicable to but a minority of cases; it was doubtless but palliative. Any surgeon who was prepared only to do a Bottini was an extremely dangerous consultant. Sooner or later he would either operate and fail, or else allow his patient, whose only relief lay in prostatectomy, to die a miserable death.

A Further Report on Permanent Catheterization.—Dr. J. R. Eastman, of Indianopolis, made this report. The catheters in fifteen cases had been retained from two days to two months. No urethritis followed this treatment, and if the catheters were large, soft-rubber instruments, the results were gratifying. The advantages of the treatment were as follows: (1) The urine drained by the natural route; (2) the urethral lumen was enlarged; (3) pain and temperature were slight or negative if the catheter was not passed too far into the bladder; (4) it was free from danger.

Fallacies in the Treatment of Urethral Diseases.—Dr. Robert H. Greene, of New York, read this paper. Stimulated by a masterful Polish report, he and Dr. Harlow Brooks had conducted a series of pathological investigations of thirty enlarged prostates which in every respect proved corroborative. Prostatic hypertrophy was inflammatory rather than cysto-adenomatous, as usually taught. There was good evidence to show that many of the prostates which enlarged were stimulated to this by the adjacent hyperplasia in the posterior urethra, which had resulted from chronic urethritis.

Perineal Prostatectomy.—Dr. Parker Syms, of New York, read this paper. He felt sure it was the operation of the future. He modestly affirmed that good fortune rather than skill had granted him in his considerable number of cases a freedom from mortality. There was no object in making a suprapubic incision if all the work could be done from below. He showed his contrivance for pulling the prostate into view. It consisted of a simple rubber tube with a bulb at one end. Into this bulb, after its insertion into the bladder through the perineal wound, a quantity of water sufficient to dilate it three inches was forced in. An assistant pulling upon the tube easily dragged the prostate into view. It was then enucleated from left to right. The death rate, as yet lamentably high, would lower as soon as these cases were operated on at an earlier date.

Dr. R. H. M. Dawbarn, of New York, said that he would demonstrate his method of intermittent bladder drainage rather than discuss the papers. The apparatus requisite for his technique consisted of some rubber tubing, a douche bag, and a hard-rubber T-tube. It was the principle of intermittent siphonage devised twenty-five years ago by a dentist named Snow for draining the saliva from the mouth. Simplest of all known methods, this application of Snow's principle by Dr. Dawbarn to the drainage of bladder and other cavities was the most serviceable to the general practitioner as well as to the surgeon. It kept the bed as dry as the De Pezzer tubes, or the Kader method, or the plan of Blasucci, and in addition to its cheapness and simplicity had the advantage over these methods that one could easily wash out the thick, stringy mucopus, slime, clots, and calcareous material, so regularly present, which made trouble for the tight-fitting tubes of other methods.

Dr. Rokey, of Oregon, declared emphatically that as yet not enough attention had been given to the prostate. The best method was the one which removed the obstruction with minimum injury to the tissues. He believed the recto-vesical technique the best, but differed from Guitéras and Fuller in advocating as small perineal incisions as possible. There was no age limit.

Dr. Warner, of Ohio, stated that prostatectomy should not be an operation of last resort. A realization of this was more important even than the elaboration of new techniques.

Dr. Andrews, of Chicago, cordially indorsed the auto-suture. He had done the Bottini operation seventeen times, with thirteen failures, one death, and three cures.

Dr. McGowan, of Los Angeles, always advised prostatectomy if possible. He had operated on fifty patients, varying in age from sixty-three to eighty-one. The results could not be expected to be perfect because the bladders were invariably diseased. Fuller's was the best technique. The least particle of prostate left behind invited relapse. He advised the Bottini method if the radical procedure was refused.

Dr. Guitéras, in closing, said that the bladder should never be emptied too quickly; even in cases of extreme dilatation not more than one pint should be removed. A few ounces more than this had caused hæmaturia from the bladder walls or even uræmia. It was important to improve the bladder conditions prior to operation. Dr. McGowan was right in saying that old diverticulated bladders could not be made good, but they did remarkably well. Prostatectomy was where hysterectomy was ten years ago. With so many working, we should soon have a good technique.

Dr. Fuller, in closing, said that every good surgeon would naturally have his own special technique. He could not agree with Dr. Greene that urethritis was the causative factor of enlarged prostate. One argument against this was that the Chinese and Asiatics in general were almost exempt, but they probably had more venereal disease than all the rest of the world. The French view of hopelessness was fallacious. The bladder did regain tone; there was use. He believed that all scars caused by electricity contracted.

Dr. Greene, in closing, said that he did not expect to have his theory accepted. It would naturally not be a popular one. If, however, it be shown to be true, it would affect the treatment as follows: (1) the chronic urethritis would be treated long and persistently; (2) early operation would be done, thus avoiding either a Bottini or the radical operation by a partial removal of the gland.

Pneumectomy and Pneumotomy.—Dr. J. B. Murphy, of Chicago, read this paper. By chest surgery, he said, we understood the immediate opening of the mediastinal or pleural cavities. Because of the danger of immediate death, but little progress had been made in the surgery of the bony basket of the chest. The dangers had been classified as follows: (1) Primary pneumothorax; (*a*) shock, (*b*) collapse, (*c*) dyspnœa. (2) Primary hemorrhage; (3) secondary pneumothorax; (4) sepsis. The conditions arising in (1) were these: (*a*) one lung was thrown out of action, (*b*) the right heart circulated into the left, (*c*) the vagus was squeezed by the lung, (*d*) deflection of the mediastinal septum and pinching of the cava at the diaphragm occurred. Such had been the various condition brought forward to explain the appalling state into which a patient fell when his pleura was open. Dr. Murphy, however, held them all to be fallacious. The causes were purely mechanical. They arose, as he had frequently shown in dogs, solely from a deflection of the septum, which was not a solid body and which, being forced by atmospheric pressure far into the uninjured side, practically prevented the action of the unimpaired lung. How could we overcome the effects of pneumothorax? There were two ways: (1) by immobilization of the mediastinum by a clamp on the hilum on the lung; or (2) by insufflation. The Parham-Matas instrument in possessing a gauge was of particular value. The hemorrhage he divided into external and internal. When the chest was entered far more danger occurred from hemorrhage of the mammary than from injury to the intercostals. The mediastinal septum was a little to the left of the mid-line, so that there was danger of injury to the pleura in operating on the right side. There were three great dangers from internal hemorrhage of the lung: (1) Azygos vein; air embolus was very probable from this accident. (2) Subclavian; but this occurred only in some form of tuberculous contraction. (3) Right auricle; which also in tuberculosis might be adherent and displaced. This visceral hemorrhage was positive or negative according to the area involved. The pulmonary artery was of enormous size, but because of the vast number of branches given off in the earliest part of its course, the twigs soon became small. In these, there was only one-fourth the pressure found in other parts of the body, and here beyond the so-called "hemorrhagic area" this factor was of the utmost value to the surgeon. In lung surgery the angiotribe was destined to be of the very greatest value. By it not only was all hemorrhage evenly controlled, but the third great danger of which he spoke—secondary pneumothorax—was absolutely prevented. Whether in the large bronchi, purulent and diseased, the angiotribe would make as perfect a union as it did in the normal tubes was not yet known. But in dogs he had repeatedly closed the first and second bronchi with absolute success. Sepsis arose from three sources: (1) it might be primarily induced at the operation; (2) it might come at the time of operation from the breaking of a focus; (3) it might be secondary, from an infected bronchus. He felt that chest surgery had a wonderful future, and that, armed with the invaluable Matas instrument; with the angiotribe; with the innumerable electrical devices of the day, the surgeon would be as able to explore this almost unknown region as freely as he did the abdomen to-day.

Removal of Foreign Bodies from the Trachea and Bronchi.—Dr. DeForest Willard, of Philadelphia, presented this paper. Particularly in children the number of foreign bodies which were apt to be sucked into the trachea were almost without number. The immediate effects were most alarming. In the majority of cases the first paroxysm of coughing usually dislodged the body if it had not reached the larynx, but it was unfortunate that there were a great many cases not so happily terminated, in which the seed or the toy passed on to become impacted in the right bronchus. This it might partially or totally close. In the latter case gangrene of the lung would usually supervene. In the absence of apparatus to do a tracheotomy, inversion of the child was dangerous, since the body dislodged from the bronchus might become fixed in the larynx and cause immediate death. Before any operative procedure was undertaken for the relief of this condition, a physical examination of the lung was absolutely necessary, as numerous patients suffering from pneumonia had been operated on for supposed foreign body in the bronchus. In the event of operating, one expected the offender to be discharged through the tracheotomy opening as soon as it was made. This, however, while the rule, was not by any means invariable. The next step was to practise bronchoscopy. For this there was nothing better than an ordinary cystoscope, which, introduced through the opening, gave a beautiful view of the whole area. A Bigelow evacuator attached to a large rubber tube would sometimes afford a means of securing the object, if it be small, by suction. The tracheal forceps, so constantly used, should be handled with the utmost caution, because without doubt in many instances it had wrought great harm. If the object cast a shadow with the *x*-ray, a skiagraph might prove of great value,

provided fixed angles of illumination were employed. If the object could not be secured through the trachea, pneumotomy might be practised, but as yet it must be considered one of the gravest of surgical operations. One technique was to saw the sternum longitudinally and reach the lung through the mediastinum. The bronchus might also be reached through a large trap door, either anterior or posterior. If gangrene of the lung had occurred, a free incision should be made into the diseased lung substance and thorough drainage employed. The Parham-Matas instrument had removed many of these dangers, and was a great step forward in thoracic surgery. His conclusions were as follows: (1) Since the foreign body had entered by the larynx it could escape from it; hence the attendant should invert the patient, being prepared to do instant tracheotomy. (2) The *x*-ray was often of value. (3) Tracheotomy was the first operative step. (4) The next was bronchoscopy. (5) Suction; magnets. (6) Prolonged instrumentation was contraindicated. (7) Careful physical examination of the lungs should be made. (8) The chest walls should be opened only with all apparatus at hand.

Treatment of Empyema.—Dr. James H. Dunn, of Minneapolis, presented this paper. Pulmonary sclerosis, he stated, was one of the great factors in prolonging this condition. No fluid should be removed from any chest without being subjected to most thorough bacteriological examination. Few cases yielded to expectant treatment or to paracentesis; the proper course was immediate resection of a rib. of which at least 6 cm. should be removed. Irrigation of the cavity was probably of little value at any time, and immediate washing out was extremely dangerous. As to draining the cavity, gauze was infinitely better than were tubes. There was very great danger of post-operative infection, which should be most strenuously guarded against. Opiates should be avoided; for an active cough, expanding the lung, was greatly to be desired. Estlander's operation was being superseded by Shadey's, in which all the chest wall but the skin was removed. This then fell upon the lung and obliterated the cavity. His conclusions were as follows: (1) In pneumococcus infection aspiration should be done at least twice before resection. (2) In pure tuberculous effusions waiting was necessary until the infection be mixed. (3) Double resections should not be done. (4) Local anæsthesia could be used if necessary. Ether was contraindicated. (5) The position of the patient was important. (6) The rib was best cut by a wire saw. (7) The opening should be made at the lower and posterior site of the collection. If too low the diaphragm would often overlap and close it.

Dr. A. C. Bernays, of St. Louis, opened the discussion. The time was approaching, he said, when the chest surgeon should have the care of those cases of tuberculosis with mixed infection that were now sent to the mountains of the West. It was unfortunate that as yet it was practically impossible to obtain the consent of a patient for operation—or, indeed, that of his attending physician—until he was practically moribund. He related his experiments on a series of eight cases in which he had removed the upper part of the lung in cadavers dead of pulmonary tuberculosis, in ninety per cent. of which he was able to accomplish this without entering the pleura. He advised an incision over the second rib. This was cut anteriorly, seized, and broken off. This exposed the apex of the lung and enabled one to search for cavities with the utmost freedom.

Dr. Frank, of Chicago, said that lung surgery was not so easy as some of the speakers might have led us to suppose. It was now in just about the condition that the surgery of tuberculous joints was twenty years ago.

Dr. Wills, of Los Angeles, said that he was glad so much attention was being accorded this very important problem by the Eastern surgeons. It was a question of vital import to the dwellers on the Pacific Coast, where countless numbers of hopeless tuberculous patients were sent to die and to infect those almost sterile regions. He related a case of a patient on whom three years ago he had performed an extensive pneumotomy, and who, snatched from the grave, was now enjoying excellent health.

Dr. W. W. Keen, of Philadelphia, spoke first of the need and mode of causing adhesions between the lung and pleura before opening a pulmonary abscess which would otherwise drain into the chest; second, of his mode of suturing a large area of the lung around the margin of a thoracic wound as a means of averting primary pneumothorax.

Dr. Willard said, in closing, that secondary emphysema, which came sooner or later in the event of our not closing the bronchus, was one of the gravest sequelæ of pulmonic surgery. It was progressive and would cause death. All abscesses should be opened and drained. Adhesions should always be provoked, unless already present, before cavities were opened.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Third Day—Thursday, June 6th.

A New Operation for Retro-displacement of the Uterus.—Dr. Emil Ries, of Chicago, presented this paper. The advantages of the vaginal route, he stated, were: (1) It exposed only a limited area; (2) shock and the danger of sepsis were minimized; (3) it required less handling of the intestines and less adhesion as a consequence; (4) it did away with a visible scar; (5) there was no ventral hernia; (6) there was but a short detention in bed, and the after-treatment was very simple. Vaginal fixation as ordinarily employed was a failure; because, if the uterus was fixed too close to the anterior vaginal wall, there would be trouble should pregnancy occur; if loosely attached, there would be a return of the displacement. With other methods of shortening of the round ligaments, the uterus was held by unstable adhesions, and kinking of the Fallopian tube was common. By the new method the ordinary vaginal incision was made, and the uterus and appendages were brought out. The round ligament was detached from its peritoneal covering by a blunt dissection, and a catgut ligature was passed through each ligament. On the anterior surface of the uterus, on a level with the tubes, a tunnel one inch long was made through the uterine tissue by means of an artery forceps. The round ligament on one side was drawn through the tunnel by means of its attached catgut ligature. The same thing was done with the round ligament on the other side, and each was anchored at its point of exit from the tunnel. The raw surface at each end of the tunnel was now covered with a few sutures. By this means there was a very slight loss of blood, only a few stitches were placed in the uterus, and the patient left the hospital within a week. In all the cases examined, one year after the operation, good results had been found. In all, twenty cases had been subjected to this method.

The Surgical Treatment of Retroversion of the Uterus.—Dr. Franklin B. Martin, of Chicago, stated that there had been more than fifteen modifications of the ordinary Alexander operation, yet none of them had been perfect. The following operation had afforded him the best results in simple retroversion free from adhesions. The ordinary Alexander incision was made on both sides. A pair of forceps was passed from one side under the skin and superficial fascia, and after grasping the ligament of the other

side it was drawn through to the opposite side. The two ligaments were then tied in a knot, the uterus having previously been brought forward. Sixty-one cases had been subjected to this method in five years, with uniform success. There had been six pregnancies among these patients, without any evil results. By this operation we secured: (1) Uniform shortening of the ligaments; (2) a permanent and strong fixation of the ligaments; (3) an accomplishment of this result without the necessity for placing sutures of any kind, temporary or permanent, for the purposes of fixation and shortening; (4) the elimination of the possibility of fistulous tracts being established, because of the infected deep, permanent suture, and obviation of any separation due to buried absorbable suture; (5) this method of fixation seldom gave rise to any pain at the point of attachment of the ligaments, like that frequently complained of when the ligaments were attached separately by the permanent suture. For cases of extensive adhesions the author had devised the following method: The ordinary incision was made through the abdominal wall as for ventro-suspension; a strip of peritoneum one-half inch long, extending along one side of the incision for about two inches, was dissected off, leaving the lower end attached to the abdominal wall. A Cleveland ligature carrier was passed through the structure of the uterus behind the fundus, from behind forward; the strip of peritoneum was grasped by the ligature carrier and drawn through the muscular issue, and then brought up and attached to the abdominal wall at the place from which it was detached. A small fixation catgut suture was now passed through the uterus, as in the operation for ventro-suspension, and the incision closed. In some cases the urachus might be used instead of the peritoneal strip. By this method there was no form of permanent buried suture. It secured permanent fixation with free mobility, and did not interfere with pregnancy. The writer presented a tabulated report, covering a period of four years, and including one hundred and seventy-three cases, with a mortality of three and a half per cent. There were three failures. There were two cases in which pregnancy subsequently occurred. Serious mental disturbance existed previous to the operation, and was the paramount symptom for which relief was sought in nine cases. All of these patients were absolutely well now.

Dr. J. Riddle Goffe, of New York, said that the uterus was not supported by the perineum. The utero-sacral and utero-vesical ligaments were the main supports of the uterus. If we could keep the cervix well up in the hollow of the sacrum by the shortening of the utero-sacral ligaments, we would have the ideal method. Thus far, it had been impracticable. Simple retroversion was not a very serious condition. He made a loop in the round ligaments and fastened the loop to the anterior surface of the uterus. Since he began to use silk as a suture material six years ago he had had no failure.

Dr. W. H. Humiston, of Cleveland, Ohio, believed that in simple retroversion a thorough curettage and the use of a suitable pessary for three months would cure most of these cases.

Dr. A. Goldspohn, of Chicago, stated that in all operations having the production of adhesions as a basis, recurrence was extremely common after pregnancy.

Dr. Howard Kelly, of Baltimore, had done more than six hundred abdominal fixations by his method with two per cent. of relapses. Out of a series of two hundred and fourteen cases, forty-three patients became pregnant, and in no case was there any trouble during labor. Recently he had devised a new modification of the round-ligament operation. A hole was made in the broad ligament, and the round ligament was pulled through and anchored behind.

Dr. McDermott, of Chicago, related the history of a case of pregnancy interfered with by adhesions, due to operation for retroversion, in which he opened the abdomen, freed the adhesions, and the case went on with successful termination.

Dr. E. E. Ries, of Chicago, stated that the small cysts found in the ovary were normal, caused no symptoms, and need not be disturbed.

Dr. Martin, in closing, stated that in his experience, simple retroversion could be cured by local treatment and the use of the pessary in but one out of four cases. By the methods he had described, there were no hernia and no mortality.

Position of the Patient during Delivery.—This paper was presented by Dr. W. D. Porter, of Cincinnati, Ohio, who held that puerperal infection was most likely to occur during the later part of labor from fecal matter. To obviate this, the patient should be put across the bed with her hips well down to the edge and the legs extended. They were held by assistants or placed on the backs of chairs. This position was not tiresome. The operator sat in front between the legs and cleansed the external genitals with an antiseptic solution. This position insured control of the head and perineum because the patient could not change her position. After the delivery of the child there was less danger of infection of the cord than by ordinary methods. This position should be maintained through the entire second stage of labor.

Prophylaxis and Treatment of Puerperal Sepsis.—This paper was read by Dr. J. F. Moran, of Washington, D. C. In the pre-antiseptic days from 1786 to 1826, the total death rate from sepsis in the several great maternity hospitals in Vienna and Dublin did not exceed six-tenths of one per cent. We could show scarcely any better results at the present day. The commonest cause of severe sepsis was the streptococcus. Infection by staphylococcus and colon bacillus was much milder as a rule. The vulva was scarcely ever free from pathogenic germs. The acids produced in the vagina generally prevented the growth of virulent organisms there. Recent observations upon four thousand cases, in which one-half were given antiseptic douches, showed that the morbidity was much less in cases that were not douched. Rubber gloves were essential for clean obstetrics. In the treatment of puerperal sepsis great care must be used in curetting and in the use of strong antiseptic solutions. In differentiating between sepsis due to the streptococcus and other organisms, it might be mentioned that the pulse rate was found higher, altogether out of relative proportion to the rise of temperature, and the constitutional symptoms were more severe in streptococcus infection than in sepsis from other causes. In staphylococcus or colon bacillus infection, the temperature might be high but the pulse was lower. The author had employed antistreptococcic serum in several cases of pure streptococcus infection, with the happiest results. Hysterectomy should never be done for puerperal sepsis.

Indications and Contraindications for the Use of the Curette in Obstetric Practice.—Dr. H. C. Fry, of Washington, D. C., maintained that whenever possible the finger should be used instead of the curette for cleaning out the uterus. The use of the curette in cases of streptococcus infection was extremely dangerous because there was a protective zone thrown out by nature in most of these cases, which the curette broke down and general septicæmia followed. If a saprophytic infection was present curettage was indicated. Often this might be determined by the foul-smelling discharge, which was indicative of saprophytic infection. If one were in doubt, cultures should be taken, followed by a preliminary injection of salt solution. Agar formed the best medium for the growth of strep-

tococci. The growth could be made out plainly within twelve hours.

A Case of Streptococcus Infection Following Labor.—Dr. W. H. Humiston, of Cleveland, reported this case, in which immediate drainage of the peritoneal cavity was secured by incision in the cul-de-sac through the vagina. A grayish slough on the torn surfaces of the cervix, resembling in every respect a diphtheritic patch, was proved to have been produced by the colon bacillus. Since adopting vaginal incision and drainage, the author had not lost a case of puerperal sepsis when the septic foci were confined to the pelvis.

The Practice of Obstetrics as it Is and as it Should Be.—Dr. E. Gustav Zinke, of Cincinnati, Ohio, held that all women should be delivered by the family practitioner in the maternity hospital, because in no case could we be prepared for all emergencies in a private house. The scarcity of physicians who restricted themselves to obstetrics was because the remuneration at present was too small.

Dr. Kates, of Minneapolis, said that if a digital examination of the interior of the uterus was made and a smooth surface was felt, the streptococci were likely to be the cause of the infection. If a rough surface was found, sapræmia or a mixed infection was more likely. In these latter cases it was safe to curette.

Dr. Henry, of Omaha, said he curetted all cases and then thoroughly cauterized with carbolic acid.

Dr. J. W. Bovée, of Washington, advised that a wet antiseptic pad be kept on the vulva during labor and for several days thereafter.

Ectopic Gestation.—Dr. W. H. Wathen, of Louisville, stated that ectopic gestation was never primarily abdominal. There had been only one case of ovarian pregnancy reported before the one here exhibited. Tubal pregnancy was the most common form of ectopic gestation. In the treatment, the author advised that before rupture the vaginal method of extirpation was usually to be preferred. After rupture, when the blood was confined between the layers of the broad ligament or in the cul-de-sac, and in intra-abdominal rupture, when there was but little hemorrhage and in all other conditions, the suprapubic method was preferable. In cases beyond the third month, when the placenta could not be entirely removed, an incision should be made in the pouch of Douglas and the sac stitched there, shutting it off entirely from the abdominal cavity in the same manner as an intraligamentous cyst was treated.

The Increasing Sterility of American Women.—Dr. George J. Engelmann, of Boston, Mass., stated that the sterility of woman had increased hand-in-hand with the much-discussed decrease of fecundity everywhere to some extent, but in the United States to an excessive degree, as fecundity had diminished more rapidly here than in any other country. From a sterility of two per cent. of the eighteenth century and a fecundity of five children to the marriage, conditions better than in any other country, and such as led to the Malthusian theory of super-fecundation, we had gone to the other extreme, and now the sterility was greater and the fecundity less than that of the women of any other nation except France. The generally accepted ratio of sterility among civilized nations was eleven per cent. In this country the average was twenty per cent. In some States it reached twenty-five per cent. The fecundity in some parts of Europe reached eight to the family. The average was five to a marriage. In this country at present it was but two to each marriage. The sterility of foreigners in this country was thirteen per cent. Among college graduates sterility reached thirty-three per cent. The English Canadians in all these relations came under the same category as the women of the United States. The French Canadian had the highest fecundity of any nationality, amounting to nine to every marriage. Among college graduates there were but one-and-four-tenths children to each marriage. Normally, there was one miscarriage to every three-and-one-half labors; in the United States, one to every two-and-one-half labors. In Canada there was but one divorce to every sixty-three thousand marriages; in France, one in twelve thousand five hundred; in all the United States, one in one hundred and eighty-five; in Rhode Island, one in eight marriages. This condition of sterility went hand-in-hand with increase in divorce. There was an absolute and primary sterility due to utero-ovarian disease, mainly atresia, gonorrhœa, and endometritis with acrid discharge that was destructive to the spermatozoa. This was to be distinguished from secondary sterility, *i.e.*, conception and miscarriage. This primary sterility was much less frequent, twelve per cent. among Americans, three to six per cent. among foreigners, showing that among American-born there was a much greater proportion of sterility due to abortion. Once in four or five cases a sterility was due to the male. That this sterility was not mainly due to utero-ovarian disease was evident from the rapid increase hand-in-hand with the progress of gynæcological skill, which we have every reason to believe would reduce the number of childless women to a minimum if sterility were referable to tangible physical causes. The causes were moral rather than medical. The facts in this paper were based on records and statistical data gathered in various parts of the country, each one of which corroborated the other.

Dr. W. H. Duff, of Pittsburg, condemned the course of editors who allowed insinuating advertisements for the production of abortion to appear in the daily press.

Dr. E. D. Ferguson said that a great deal of the sterility was due to double epididymitis in the male. The paper was further discussed by Drs. Wathin, of Louisville, C. Graham, of Indianapolis, Coy, of Duluth, and Porter, of Fort Wayne.

Dr. Engelmann, in closing, said that in animals abortion occurred in twelve per cent. Epidemics of abortion had occurred often in large herds. Antiseptic precautions had successfully been employed in the governmental experimental stations in such epidemics.

GENERAL SESSION.

Fourth Day—Friday, June 7th.

Effect of Report on Reorganization.—The President said that as some confusion existed concerning the effect of the plan of reorganization on the present meeting, he would rule that the new constitution went into effect at the present session only so far as it concerned the election of representatives of sections to the House of Delegates, and that all standing committees, and all special committees created by the general meeting at the present annual session, should report next year to the House of Delegates.

Oration on State Medicine.—By Dr. Kober (see page 898).

Rockefeller's Donation for Research.—The following preamble and resolutions were unanimously adopted:

Whereas, Mr. John D. Rockefeller, of New York, appreciating the great importance and humanitarian utility of medical research, has recently donated the sum of $200,000 for the promotion of original investigation, and has placed the control of this sum in the hands of a committee composed of representative medical scientists under the able chairmanship of Dr. William H. Welch, of Baltimore;

Resolved, That the medical profession represented by the American Medical Association desires to express its appreciation of this generous gift and the gratifying fact that the needs of scientific research in medicine are so fully appreciated by the donor;

Resolved, That a copy of these resolutions be presented to Mr. Rockefeller.

Decisions Affecting Membership.—The Judicial Council reported through its secretary, Dr. Frederick Holme Wiggin, of New York, that it had ordered the names of certain members dropped from the roll because of their having been already dropped by their local association for arrears of dues, the same to continue in effect until such time as these persons should see fit to pay all indebtedness to said association. The council also instructed the secretary of the American Medical Association to notify those who had severed their connection with the local organization in affiliation with the national body, as well as those who had moved to other States or counties without having secured membership in the local affiliated organization of their new residence, that if they did not after a reasonable time secure membership in such local affiliated medical association, their names would be removed from the list of members of the American Medical Association. This action of the council was final, there being no higher court.

Restoration of Army Canteen Favored.—On the recommendation of the committee on legislation, the following resolutions were adopted:

Resolved, That this body deplores the action of Congress in abolishing the army post exchange or canteen, and in the interests of morality, discipline, and sanitation recommends its re-establishment at the earliest possible date;

Resolved, That the United States Congress be petitioned to repeal at the earliest possible moment the objectionable law which prohibits the army canteen.

Dr. J. A. Wyeth, of New York, the president-elect, was then escorted to the chair amid great applause. There were over eighteen hundred registered at this meeting.

JOINT SESSION OF SECTIONS ON PRACTICE OF MEDICINE, HYGIENE, AND SANITARY SCIENCE.

Fourth Day—Friday, June 7th.

Further Report on Pseudo- or Modified Smallpox.—Dr. T. J. Happell, of Trenton, Tenn., said that last year he had reported to the section his experience based upon three hundred cases of pseudo- or modified smallpox, made from a bedside study of the disease in all stages. He now spoke of some of the anomalies met with in four hundred cases that had recently come under his observation. In many instances the disease was non-communicable. Many vaccinated persons contracted the disease, whilst many who had not been vaccinated escaped. The following differential points were presented: In the modified form there did not appear to be any prevailing types of the disease, the cases differing only in degree. The incubation was from fourteen to eighteen days. In smallpox, the varieties were varioloid, discrete, hemorrhagic, and confluent, and the incubation period was from fourteen to twenty-one days. The symptoms were stated to be as follows. From the first to the third day: In the modified form, at the onset the patient complained of cold; felt as though an attack of grippe or tonsillitis was coming on. The temperature was 102°–105° F. There was little or no vomiting. The pulse was full and rapid. Little or no prostration, and no delirium were present. No convulsions occurred in the young. In a few cases there might be sleeplessness. In smallpox the onset was sudden, with violent chill, persistent vomiting, agonizing pain in the back and head, and shooting pains in the limbs. The temperature was 103°–104° F. The pulse was full, strong, and rapid. The prostration was great from the onset. The eyes were injected. Sleeplessness, delirium, and convulsions occurred in the young. Third day: In modified smallpox no coarse red spots appeared. In smallpox coarse red spots appeared on the lips and forehead. With the appearance of these spots the temperature fell to the normal and the patient was comfortable. Fourth day: In the modified form an eruption appeared, whose character was generally that of an acne. In some rare instance the shot-like papules appeared. The temperature fell to the normal, and the patient almost invariably got up, if he had gone to bed, and said he was well. The eruption first appeared on the face: in men, about the forehead, cheek, and chin; in women and children, irregularly about the face. There was usually a sore throat. In smallpox the small red spots appeared on the forehead at the margin of the hair, later on the extremities. Papules followed the red spots. They had a shot-like feel. Fifth day: In the modified form the acne-like eruption and papules developed into vesicles which assumed an opalescence at once. These vesicles were unicellular and were not umbilicated. The serum which exuded at their apices dried and turned brown, and this in some cases gave them the appearance of umbilication. There was no puckering of the vesicle at its border. The temperature was generally normal unless it rose from abscess formation or other causes. The vesicle might dry up and the disease might be said to have aborted. A rapid recovery followed. In smallpox papules appeared on the wrists and forehead. Sixth to the ninth day: In the modified form the vesicles became filled with an opaque lymphoid fluid; in some cases with a brown nucleus in the centre, which gave it an umbilicated appearance. This vesicle, with its opaque fluid miscalled pus, shrank to half its diameter and became a thin brown scab, perfectly circular. The patient felt well and hungry after the appearance of the eruption. The latter occasionally affected the conjunctiva. There was no secondary fever. By the tenth day the skin might be entirely clear. In true smallpox vesicles appeared in place of papules, and the eruption spread gradually over the entire body. The vesicles were umbilicated and multilocular. On the eighth and ninth days the vesicles became pustular. Tenth to twelfth day: In smallpox pus oozed and formed scabs, and the stench was particularly bad. Seventeenth to twenty-first day: In smallpox the scabs dropped off, leaving red glistening pits which soon became white. Ulceration was deep. Ophthalmia was generally present. Pustules pervaded the mouth, larynx, pharynx, and trachea. As to papules, in the modified form, when these were present, they were the same size as in smallpox, perhaps a little smaller, but fewer. There might be none. The vesicles ranged in size from the head of a pin to a split pea. They were not umbilicated and when punctured collapsed. The vesicle was unilocular. Convalescence began at the appearance of the eruption. The so-called pustule did not extend into the derma. The epidermis was the only structure of the skin involved; hence there was no pitting. Those vaccinated contracted the disease. In smallpox the papules were about the size of No. 4 shot and had a translucent appearance. They occurred on the entire body, including the palms and soles, appearing first on the face and hands. The vesicles were umbilicated and multilocular. So was the pustule and neither would collapse in toto if pricked with a needle.

Smallpox; the Old and the New.—Dr. W. L. Beebe, of St. Cloud, Minn., stated that he had been identified with two epidemics (twenty years apart) and though they were evidently both smallpox they were

very dissimilar in many characteristics. He thought that many of the recent cases had been diagnosticated chickenpox when they were really smallpox.

The Sanitary Features of Smallpox.—Dr. Louis Leroy, of Nashville, Tenn., held that a competent physician should be placed in charge and given absolute power to act; he should communicate with boards of health. Daily official reports should be made to newspapers, stating the exact condition of affairs. Smallpox treatment in private was really a make-shift. Complete and perfect isolation should be insisted upon. Everything possible should be destroyed by burning after the patients had been discharged. He advocated the hypodermic needle as a means of introducing vaccine virus beneath the skin, in aqueous solution or glycerinated lymph. A solid piston hypodermic needle was used, and a drop of the lymph was forced into the skin, not beneath it. It had many advantages; in cases of compulsory vaccinations it could not be washed off; there was absolute freedom from infection at the time of vaccination. It was painless and no immediate dressing was necessary.

The Diagnosis of Mild Smallpox in the Present Outbreak.—Dr. Heman Spalding, of Chicago, stated that on February 15, 1899, smallpox had been introduced into Chicago from Cincinnati; and in the seventeen months following there had been seventy-two cases, twenty-five of which were direct importations. For a period of three and a half months there was entire freedom from the disease. Then there occurred another outbreak. These two outbreaks gave him an opportunity to study 310 cases in the Chicago Isolation Hospital. One hemorrhagic case proved fatal; 13 were confluent (3 deaths); 24 semi-confluent (2 deaths); 54 severe discrete (no deaths); 179 mild discrete cases (no deaths); 39 modified form (no deaths); 271 of these had never been vaccinated. The term varioloid should not be used. None of those afflicted with the mild form of the disease contracted smallpox from the severer typical cases in the wards, where the exposure had been prolonged and certain. The mild form of the disease gave immunity from smallpox and yet would transmit typical confluent or hemorrhagic smallpox.

The Distinguishing Characteristics between Mild Discrete Smallpox and Chickenpox.—Dr. Frederick Leavit, of St. Paul, made the following summary:

	Smallpox.	Chickenpox.
Age	Any age	Childhood.
Incubation	Two weeks	Thirteen to seventeen days.
Invasion	Marked headache, backache, fever, general malaise, lasting three to four days.	Is none, or at most only slight; worse in the covered portions, thorax.
Surfaces attacked	Worse on the exposed parts, extremities; invariably on the palms.	Rarely or never seen on the palms or soles.
Character of the eruption.	Progressive; papules, vesicles, pustules, crusts.	Papules and crusts; lesions very superficial; easy to rupture.
Histology	Lesion includes the lower layers of the derma; hard to rupture; multilocular.	Unilocular.
Temperature	Remains high (103–105°) till eruption appears, then drops and does not rise again for a week, and not then in the milder discrete forms.	Rises with the severity of the attack.
Contour of the eruption.	Quite uniform in size; has a reddened area at base; frequently umbilicated.	Not uniform; also inflamed area about the vesicle, but less marked.
Sensation	Painful to the touch; may itch.	Not painful to touch.
Duration, including period of invasion and desquamation.	Two to four weeks	One week to fourteen days.
Vaccination	Protects	Does not protect.
Pitting	When confluent on face will occasionally mark in the discrete form.	Seldom unless infected.
Complications	Generally none	None.
Mortality	High in severe confluent and hemorrhagic types.	Nil.
Resolution	By crisis	By lysis.

Variola.—Dr. H. M. Bracken, of St. Paul, stated that in the State of Minnesota there had been reported 7,211 cases of variola, with 49 deaths, during the past two and a half years. He did not think one could be governed in the diagnosis of all cases in this present epidemic by the usual text-book descriptions of variola. Typical prodromal symptoms might be present, but the rash might vary in degree, in form, in type, progress, and final disappearance. Of 662 cases in 244 houses, but 10 patients had been successfully vaccinated at any time prior to their infection, and of these 10, thirty years had elapsed since successful vaccination for two of them, over twenty-five years for four of them, twenty years for one, and six years for one. The Chicago board of health made the following statement: "Out of a total of 171 cases of smallpox found in Chicago between November 30, 1900, and April 10, 1901, 140 had never been vaccinated. Of the remaining 31 cases, 29 were adults showing faint, poor, or irregular scars, claimed to be evidence of attempted vaccination in infancy or childhood—the most recent being twenty-three years old. Only 2 out of the 171 cases exhibited typical scars of successful vaccinations. Since vaccination had been made compulsory in the schools of Chicago smallpox has disappeared from them. The degree of immunity depends, in part at least, upon the intensity of the infection. Marson gives the following death rate among those who have been vaccinated: One cicatrix, 7.73 per cent.; two cicatrices, 4.7 per cent.; three cicatrices, 1.95 per cent.; four or more cicatrices, 0.55 per cent."

Dr. J. M. March, of Canton, Ohio, made a strong plea for accuracy in diagnosis and universal vaccination. He was of the firm conviction that the mild epidemics of the past few years throughout the country were those of variola vera.

Dr. Ricard, of Minnesota, spoke of his experience in an epideimc in which seventeen hundred and fifty-eight cases occurred. It often happened that the only unvaccinated member of a family became affected.

Dr. J. A. Barr, of Pennsylvania, dwelt upon what one should consider successful vaccination. The scar present did not indicate "successful" vaccination. He thought only those repeatedly vaccinated could be said to have been successfully vaccinated. Taking 6,000 cases, it was found that 14 per cent. were fatal among those who had been vaccinated once, and 8 per cent. of those vaccinated twice, and so on. It took as a rule four good scars to indicate immunity.

Dr. Fox said that no State was safe until this mild smallpox was stamped out.

Dr. Martin, of Mississippi, took the ground that there were different varieties of smallpox, and that they bred true. He described several varieties with the popular names by which they were known: "four spot," "yellows," "stonepox," etc. He had traced sixteen cases, all similar, to infection from a patient with identical lesions.

Dr. Happel said he had never opposed vaccination, but had strongly advocated it. He believed the present outbreak in Tennessee a hybrid disease that bore the same relationship to variola that rötheln did to measles. Vaccination did not protect against it.

The Chairman was of opinion that vaccination did protect against the mild cases described in the various papers, and placed before the section a resolution to the effect that the prevailing epidemics throughout the country were those of smallpox, and should be treated as such. This was adopted by almost unanimous vote.

SECTION ON SURGERY AND ANATOMY.

Fourth Day—Friday, June 7th.

Indications for Operation in Calculous Nephritis and Ureteritis.—Dr. C. L. Leonard, of Philadelphia, stated that the *x*-ray had shown the very great

relative frequency of ureteral calculus. The absence of symptoms showed that the ureter was extraordinarily tolerant of these stones, and now that we had a means of actually being able to watch them and study the progress they were making, we were relieved of the necessity of operating on a great many cases which heretofore demanded exploratory incision. In one hundred and sixty-five cases the certainty and accuracy of the *x*-ray as a guide for and against operation had been well demonstrated. One very valuable point which this series had shown was that over fifty per cent. of all stones were located in the ureter; another, that the urine, formerly considered so important a factor, had been shown in many cases to be negative. A distended kidney was a good rather than an evil sign, because, in the absence of neoplasm, it showed that there was a *vis a tergo* behind the stone, which experience proved would in many cases dislodge it; on the other hand, in the absence of a large kidney, this force was lacking. The employment of instruments of all kinds seemed to be less valuable than the *x*-ray. In the female, however, this was not quite so true, since in the veins of the broad ligaments phleboliths were occasionally found, and these might interfere with *x*-ray diagnosis. In the male, anuria or a complete blockage of one ureter by calculus of course indicated operation. The presence of pus, however, did not necessarily do so. Every effort should be made to clear the urine by the use of disinfecting drugs, which even in the presence of grave provocation would often accomplish a great deal temporarily, and would thus afford a safer ground for operation. Interureteral operations were facilitated by suprapubic cystotomy and by a special method devised by the author. The *x*-ray had made possible a differentiation of cases in which conservatism was good surgery, from those demanding immediate operation. It had put the question of urinary calculi on a scientific basis.

Acute Infective Cholangitis and Cholecystitis as a Complication of Gall Stones.—Dr. D. N. Eisendrath, of Chicago, formulated the following questions: (1) Do the bile passages normally contain germs? Probably not, except near their entrance into the duodenum. (2) Is bile bactericidal? It probably inhibits the growth of the colon and typhoid bacilli. (3) How and when does infection of ducts occur? Occasionally from above, via the blood; more frequently from below. Any interference with the flow of bile at once increases the number of germs in the ducts. (4) The relation between infection and gall stones, and the effect of these on the liver tissue. He then cited a case, and drew the following conclusions: When pus is present in the gall bladder, the outlook is very grave. There must be no delay in operating as soon as gall stones have been diagnosed.

Dissecting Abscesses of Abdominal Wall Producing Symptoms Simulating Pott's Disease of the Spine.—He cited also a case of typhoid fever which had been greatly complicated by a very large abscess which, forming in the anterior abdominal parietes, had eventually opened near the umbilicus. Associated with it was a compensatory kyphosis, which, even after careful study, was only with great difficulty differentiated from typical tuberculous spinal lesion. The literature showed abscesses to be not infrequent sequels of typhoid, even in parts very remote from the abdomen. It was probable that Zenker's muscle degeneration was an important factor in affording the typhoid germ, which seemed to be the most frequent source of these abscesses, an opportunity to establish itself in the tissues. Of the few abscesses which were formed in the abdominal walls, most had finally opened near the umbilicus. It was interesting that certainly at their maturation they did not in any way connect with the gut. His conclusions were as follows: (1) Abscesses of the abdominal wall occurring occasionally after typhoid are not apt to be fatal and heal well after thorough drainage. (2) If large, these abscesses often produce extensive deformity, may yield some of the typical symptoms, and, particularly as regards the kyphus, resemble heart disease.

Dr. Smythe, of Memphis, in discussing these papers, reported a case which had come to him some time ago, presenting symptoms of violent cystitis. After two weeks' futile treatment by other methods, a preliminary suprapubic cystotomy was done. The patient made a good recovery, and was discharged from the hospital. A short time after, the symptoms returned with increased virulence, and, all else failing, in the presence of free discharge of pus from the ureteral opening, in which an abundance of gonococci were found, nephrectomy was done. There was good recovery from the operation, but subsequently the man complained of dyspnœa, and on auscultation of his heart there was revealed an acute septic endocarditis. The remaining kidney seemed to suffer from a similar infection—at all events, the patient soon presented the typical signs of advanced nephritis. This was a case in which the gonorrhœal sepsis had been very generally distributed throughout the body from the kidney as a nidus. The discussion of gall stones was of particular interest to surgeons of the Mississippi valley, because there was, particularly in its southern portions, an unusual number of these cases. Whether this was due to the existence of a great deal of malarial and typhoidal infection could only be surmised. In the cases which had come under his notice, jaundice had not been associated with gall-stone colic. After the removal of the stone, he invariably washed the bladder with silver nitrate, and if he found this organ reasonably healthy, he closed it very securely by a special technique.

Dr. McGowan, of Los Angeles, had found Dr. Leonard's paper of unusual interest. He asked if the *x*-ray always and invariably gave indication of the presence of a calculus. He wondered what was the percentage of errors which had been made by this technique. Under his care, and, indeed, under his knife, there had come two so-called *x*-ray burns. One of these occupied an entire year in healing; the other one resisted treatment for eighteen months. In each he was obliged to cut away the offending tissue as freely as if it had been malignant. He would wish to know if these conditions arose with the new technique. He felt that clinical judgment in these series of cases, just as in many others, was more to be relied upon than laboratory findings. The surgical sense of the trained and experienced surgeon was of greater value than any microscopic report or *x*-ray.

Dr. Thomas, of Pittsburg, cited three cases which showed that the Harris segregator and the *x*-ray were neither of them infallible. He believed that the idea of closing the gall bladder after the removal of the stones, and in the presence of a comparatively uninjured mucous membrane, was gaining ground.

Dr. Crane, of Vermont, said that he had had an experience of several thousand cases in this *x*-ray work, and wished to emphasize that it was not the *x*-ray, but the negligence of the operator who kept his patient too near the tube and exposed him too long, which gave rise to these distressing so-called burns. The skiagram was dependent on the atomic weight of the substance casting it. Varieties of calculi had variable densities. Oxalate-of-lime calculi, for example, had a greater atomic weight than that of uric-acid stones, consequently they cast a much deeper shadow. The question of differentiation of the shadow was important.

Dr. Means, of Ohio, discussed cholangitis and

cholecystitis. It was a yet unsolved problem how gall stones formed. Was infection a secondary matter in the process, or was it a primary factor which had as yet not been thoroughly worked out? Because of the fatality of these cases, which were operated on for stones during an acute attack, and because of the comparative safety of the operation during quiescence, it was obviously of the greatest import that we should find some means of discovering the existence of stones before they produced their ordinary symptoms. He emphasized that jaundice was not by any means diagnostic of gall stones.

Dr. Davis, of Omaha, had experimented for some time in an effort to find what constituted the nucleus of gall stones. In cases which had not had typhoid fever the colon bacilli were almost invariably found at the centre of the calculus. In typhoidal cases their place was taken by the typhoid germ. Thus, although his cases were not numerous enough to admit of any positive statement, he would say that they at least agreed with the observations of others that the primary cause of calculi was bacterical infection. Once the diagnosis of gall stones was made, immediate operation was necessary. No surgeon was justified in allowing the contents of gall bladders to drain into the peritoneum. In these cases he should be as careful to wall off the area as he was in appendicitis. He protested vehemently against the closure of the gall bladder. It should be drained till every possible indication of infection had passed away.

Dr. Dunsmore, of Minneapolis, asked whether there was any difference in the liability to burn in the different types of *x*-ray machines. He emphasized strongly the importance of "clinical sense." He felt that closure of the gall bladder in properly selected cases was not attended with danger, and reported a number of cases in which this had been successfully accomplished.

Dr. Rodman, of Philadelphia, said that in his city the accuracy of the *x*-ray was considered to be of the very highest type. There it was placed by the best men far ahead of "clinical sense." He had not seen any burns, even when the rays had been flooded on the face, and this from a series of hundreds of cases in which they had been used by a colleague. Indeed, he knew of an infinite number of instances in which not even the mildest type of conjunctivitis had followed its prolonged use in the eye.

Dr. Lemon, of Milwaukee, cited two interesting cases of dissecting post-typhoidal abdominal abscesses. Both of these cases, one of them by Dr. Keen, had been mistaken for appendicitis, for the tumor was low and on the right side. They were unaccompanied by jaundice. Though the occurrence was rare, he was glad that a paper on this important topic had been presented to the section.

Dr. Bloodgood, of the Johns Hopkins Hospital, spoke of the relation of gall stones to pancreatitis. This was such a rare condition that the most careful record should be kept of every case. The work of Opie and others had shown the very important relation anatomically between gall stones and pancreatitis. In a case of Halsted's, of the acute hemorrhagic form, which after operation proved fatal, Opie was so fortunate as to find a small stone lodged in the ampulla of Vater. There it lay like a ball valve, allowing a small amount of bile to pass, so that the patient did not become jaundiced, but yet causing sufficient back pressure to drive a certain quantity into the pancreas. If the stone was lodged higher up in the common bile duct, it not only obstructed its lumen, but, because of the nearness of the pancreatic duct and the frailty of the septum separating them, it undoubtedly induced an inflammatory reaction which often developed into pancreatitis. This blocking of the pancreatic duct might be a factor in accounting for the extraordinary loss of weight sometimes seen in cases supposed to be simple obstructive jaundice. One argument in favor of always marsupializing the gall bladder, even in cases in which no stone was found, was that this procedure was now known to be curative of the chronic pancreatitis which was as yet ofttimes mistaken for cholecystic troubles.

Dr. Porter, of Fort Wayne, believed that the colic so characteristic of gall stones was not produced by the passage of the calculus at all. Both the pain and the jaundice were due to a common cause—the infection and inflammation of the tract.

Dr. Mitchell, of Missouri, asked if the pain might not be induced by the very acid character of the secretion.

Dr. Bernays, of St. Louis, did not believe the pain to be inflammatory in origin. This view he based upon the fact that there were many cases in which no lesion whatsoever was to be found.

Dr. Leonard, in closing, said that some of the points which he had endeavored to establish were as follows: First, that a great many of the stones which were now searched for would pass if left *in situ;* that a detection of even a large stone did not by any means always indicate operation. He had had failures. These he had published. The word opacity had acquired a new meaning since the discovery of the *x*-ray. Proper interpretation of a skiagraph depended on the realization that the sum of the shadows in one area must necessarily be greater than the sum in another. The negative power of diagnosis of this method was as great as the positive. Nevertheless, the clinical side must always remain a very potent factor. In reference to burns, the factor engendering them was the *x*. It was absolutely unknown. However, he believed it was not the ray, but was the effect of the current around the tube. This belief he based on the observation that his own hands had been burned repeatedly, although he rarely if ever placed them in the course of the ray. All forms of machines were equally liable to produce the lesion. He had found a grounded screen to be a great protection. He was now prepared with a considerable degree of positiveness to diagnose which conditions should be left to nature. These were more numerous than formerly supposed, for a careful observation of many cases had shown the ureters in particular to be singularly tolerant of stone.

Dr. Eisendrath, of Chicago, said that abundant evidence had been presented to show that gall stones must be treated surgically. Infection was the first factor which gave knowledge of the presence of stones. In themselves they seemed often to be dormant. All the biliary and pancreatic ducts were sterile save the ampulla of Vater. A Japanese experimenter named Mijake, in a series of experiments on dogs, in one class of which he tied the ducts, in another class of which he infected the ducts, showed that no permanent lesion resulted unless these conditions went hand-in-hand. Sudden death, so frequent in these cases of infective cholangitis of the suppurative type, was due to a paralysis of the function of the liver cells which normally disposed of the germs and their products. He agreed with Dr. Bloodgood and others that a primary suture of the bladder was dangerous; it was better either to excise it or to drain. At the end of ten days if this be done the whole tract would be found sterile.

Dr. Bullitt said that renal surgery had a wonderful future. The progress that would be made would be engendered largely by the application of the *x*-ray. Leonard's conclusions that rays of certain powers must be used in differentiating the softer shadows of objects which were more or less penetrable was the

keynote to the whole situation. Burns might be produced by any type of machine.

Dr. Keokuk, of Iowa, demonstrated a method for the treatment of fracture of the femoral neck which he felt was in accordance with anatomical conditions, and which in the twenty odd cases in which it had been given trial, had shown twenty-five per cent. of cases in which there was no shortening whatsoever. In none of the others did it exceed one inch. His cases ranged from tender years to the limit of life. The principle of his technique was that there should be traction in the body line, just as in the ordinary Bucks extension method, and also in the line of the neck of the femur. In practice he applied the ordinary Bucks extension and then cast a band of adhesive plaster, about six inches wide, around the thigh on its inner aspect close to the perineum. This was drawn outward and upward, more traction was exerted upon the lower band than upon the upper, and a weight equal to that of the Bucks extension was applied.

Dr. Thompson, of Scranton, exhibited a specimen of united neck of the femur, which he had taken from a man aged sixty-two, upon whom he had operated by Gillett's method. A bone flap, consisting of a portion of the femur and the great trochanter, was turned down; a silver nail, three-sixteenths of an inch by two and one-half inches, was driven directly into the head of the bone. The wound was closed, and a plaster spica applied from the axilla to the tips of the toes. The result was perfect. Death occurred later from heart trouble.

A Simple Operation for the Treatment of Hemorrhoids.—Dr. J. R. Pennington, of Chicago, held that these tumors were to be considered typical blood-lakes or angiomata. The aim of an operation must be to reduce the destruction of normal mucous membrane while removing all the diseased area. He simply slit the mucous membrane over the hemorrhoid, evaginated the rectum, and enucleated the angioma. Saline irrigation flowed constantly over the wound. The mucous membrane fell back, and, because of the minimum of injury done, the patients so operated upon were relieved in a most radical fashion; they had very little post-operative pain, and were usually able to be up and about on the fourth day.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Fourth Day—Friday, June 7th.

Puerperal Eclampsia: its Etiology and Treatment.—Dr. T. J. Beattie, of Kansas City, stated that the etiology of puerperal eclampsia was still a mooted question. The theory of intoxication by urea, as well as that of mechanical obstruction of the vessels of the kidney or the ureter, had been exploded. Eclampsia was not dependent on diseases of the kidney because we might have eclampsia without uræmia and uræmia was not accompanied by convulsions. In all cases of eclampsia it had been shown that the urine contained micro-organisms. No one germ could be regarded as specific. It had been shown further that pregnancy caused a retention of poison in the blood because the urine of pregnant women was less poisonous than normal. Albumin in the urine was a secondary manifestation due to the direct action of the poison on the renal epithelium in an effort at elimination. Less than one and five-tenths per cent. of urea in the urine was the most significant evidence of impending eclampsia. In the prophylaxis frequent hot baths and catharsis were the most valuable agents. Special attention should be paid to the specific gravity of the urine in these cases. During the convulsions, chloroform should be administered, followed by an enema of gr. xlv. of chloral with egg and milk. Veratrum viride was the best general drug available in this condition. If given in sufficient quantity the pulse could be kept low, and if this was done convulsions very rarely occurred. Ten minims were to be given by hypodermic injection and be frequently repeated.

Dr. C. L. Bonifield, of Cincinnati, Ohio, said that in full-blooded individuals with strong bounding pulse, veratrum viride was an absolute specific. Fifteen to sixty minims of Norwood's tincture should be given and repeated every fifteen minutes until the pulse fell below sixty. It should be kept below sixty for three or four days. In thin, anæmic patients with a small, thready pulse, veratrum viride should never be used. Chloral and morphine were the best agents in this class of cases.

Dr. Cates, of Minneapolis, stated that by limited diet convulsions could be prevented in most cases if seen early. During the convulsion chloral should be combined with veratrum viride. Albumin in the urine was a very unreliable index of approaching eclampsia. It was only when there was a low percentage of urea with the albumin that the condition was dangerous.

Dr. W. H. Plummer, of Omaha, advised rapid delivery in these cases. Eczematous skin affections bore a close relation to the production of uræmia in many cases.

Dr. W. H. Hall, of Kansas City, had witnessed marvellous results from bloodletting in these cases. As a prophylactic measure, no remedy had given him as much satisfaction as pilocarpine administered as a diuretic in doses from gr. $\frac{1}{20}$ to gr. $\frac{1}{12}$ three times a day. The paper was further discussed by Dr. Rosenthal, of Fort Wayne.

Cæsarean Section as a Method of Treatment for Placenta Prævia.—Dr. W. J. Gillette, of Toledo, Ohio, stated that the most favorable result obtained in the treatment of placenta prævia by induced labor showed a maternal mortality of five per cent., and a fœtal mortality of fifty per cent. A circular letter was sent by the author to one thousand of the largest maternity institutions in this country, inquiring into the frequency of placenta prævia. The author received reports of 105,935 deliveries, among which there were 216 with placenta prævia, or 1:481. Thirty-four mothers died, with a mortality of 15 per cent.; 96 children died, with a mortality of 34⅓ per cent. In placenta prævia centralis the maternal mortality was 22 per cent., fœtal mortality 70 per cent.; in placenta prævia partialis the maternal mortality was 11 per cent., fœtal mortality 31 per cent. None of these mothers died before the seventh month. One-third of the cases reached full term. The high mortality induced Bernays in 1893 to perform Cæsarean section for this condition with a successful result. Since then there had been nine cases reported in this country in addition to the one done by the author, four of which had been successful as regarded both mother and child. Under proper conditions placenta prævia should not have more than ten per cent. fœtal mortality by this method. For emergency cases the Porro operation should be done, as it could be done more rapidly than Cæsarean section and was most useful in this class of cases because when the patient was seen she was exsanguinated, and such a uterus did not contract well. In such a case post-partum hemorrhage and sepsis were very prone to occur. When placenta prævia once occurred it was apt to recur at each subsequent pregnancy and thereby again endanger the life of the patient. In ninety-three cases of Cæsarean section done by German operators for other causes, there had been no fœtal or maternal mortality, and there was no reason why the mortality should be greater

in Cæsarean section done for placenta prævia, provided it be done before the patient lost much blood.

Dr. A. C. Bernays, of St. Louis, advised in these cases the classical Cæsarean section as described by Kelly, of Baltimore. By the methods of tamponing most of these cases would be lost.

Dr. Engelmann, of Boston, advised the use of a rubber bag to tampon the cervix, and then the vagina should be packed tightly with gauze.

Dr. C. L. Bonifield, of Cincinnati, said that if a patient had placenta prævia once, her uterus should be curetted and repaired, and in this way we might prevent recurrence.

Dr. F. F. Reese, of Cortland, N. Y., said he tamponed the cervix by means of the child's leg, and this usually stopped the hemorrhage. The mother's life should be considered paramount to that of the child, and capital operations not employed.

Dr. Gillette, in closing, stated that he would not advise this operation to be done in the milder cases of placenta prævia and in those in which the os could be easily dilated. In the fatal cases of Cæsarean section done for this purpose, the patients had always died from shock and hemorrhage from the uterus left after the operation.

Intra-uterine Amputations.—Dr. Maher, of Oakland, Cal., reported the case of a child born with the fingers of one hand and the toes of one foot missing. Later investigation showed that the amputation was due to fibrous bands that encircled the hands and toes on both extremities. A few days later a spontaneous amputation occurred on the other side, which could be observed to be due directly to the fibrous bands. In most of the cases hitherto reported, the amputation took place early in pregnancy, and it was generally thought to be due to adhesions of the amniotic sac. In this case this was not the cause. It was the author's opinion that it was due to an excess of fibrin in the liquor amnii that was deposited on the fingers and toes.

Gynæcology: its Contributions to Surgery.—Dr. Henry O. Marcy, of Boston, presented this paper. An exhaustive summary of the statistics of ovariotomy as reported by the author showed the progressive advance that had been made in this country beyond every other nation of the globe. Ovariotomy was first done by an American. Dr. Burnham, of Lowell, was the first in the world to describe and perform myomectomy for fibroid tumors. The author reported the first cholecystotomy ever performed. The gynæcological surgeon had been gradually evolved into a general surgeon, and gynæcology as such was rapidly disappearing, although it might be considered the cornerstone of modern surgery.

Officers Elected.—Dr. J. H. Carstens, of St. Louis, *Chairman;* Dr. C. L. Bonifield, of Cincinnati, Ohio, *Secretary.*

SECTION ON DISEASES OF CHILDREN.

Samuel W. Kelley, M.D., of Cleveland, Ohio, Chairman.

First Day—Tuesday, June 4th.

Measles.—Dr. J. B. Garber, of Dunkirk, Ind., read this paper. He said that certain peculiar organisms had been discovered in the secretions of those suffering from measles. No age was exempt from measles, and recurrence was not uncommon. The blood was fluid and dark in measles, and a large number of microbes had been found in severe cases. The period of incubation had been determined quite accurately by experiment and observation to be between twelve and fourteen days. A case occurring in the author's experience was related, proving that susceptibility to this disease began at birth. If the temperature continued elevated, though the rash was subsiding, one should be on the lookout for complicating bronchitis or catarrhal pneumonia. Koplik's sign was not always present. Malignant forms might occur both in epidemics and in isolated cases.

Dr. C. G. Slegle, of Minneapolis, asserted that measles was a disease which one was never too old to contract. He believed that when Koplik's sign was present it was pathognomonic, but in his experience it had been the exception for it to be present. He could not accept the author's statement that recurrences of measles were common; when such apparently occurred, he would explain them on the supposition that measles had been confounded with rötheln.

Dr. Clifton Scott, of Des Moines, said that his practice had afforded peculiar advantages for the study of measles on a large scale, and the experience thus gained led him to differ from the author regarding the susceptibility to measles at all ages. While it was true that very young infants might contract the disease, it was equally true that many children under one year of age would not develop the disease after exposure to it. In his experience, recurrence of measles was rare, but it undoubtedly occurred. It was certainly easy to confound measles and rötheln if attention were given to the rash alone, but the lesser degree of catarrhal inflammation, the presence of post-auricular glandular enlargement, and the generally trivial character of rötheln should serve to differentiate it from true measles. The presence of Koplik's spots had aided him materially in numerous cases in making the differential diagnosis between measles and smallpox.

Dr. Brownell, of Oneonta, N. Y., said that four years ago he had had under his care the father, mother, and two children in one family, each presenting all of the characteristics of measles. Two years later he had attended these same four persons while they were sick with all the characteristic signs and symptoms of measles. An old physician who had repeatedly declared his disbelief in the recurrence of measles in the same individual, and who had seen these individuals in their first illness, was asked to see them the second time, and he was forced to admit that in this particular instance measles had occurred twice.

Dr. J. M. Postle, of Hinckley, Ill., said that he had repeatedly seen a second attack of measles, and cited cases in support of his position. He added that the internal administration, either by the stomach or hypodermically, of suprarenal extract would check the catarrhal symptoms better in the majority of cases than almost any other medicine within his knowledge.

Dr. Charles Douglas, of Detroit, called attention to the wide difference in the mortality from measles in private and in institution practice. It was much greater in institutions, and this he attributed to the inherent vices of such subjects and the more feeble state of health of institution children. It was quite common, too, he said, for children to die of measles in institutions, and that, too, without any special complications.

Dr. Barber, of Minneapolis, called attention to the frequent occurrence of endocarditis as a sequela of measles, and said that children who were allowed to run about shortly after an attack of measles, and before fully convalescent, would often be found to have a heart murmur.

Dr. Townsend, of New Lisbon, Wis., relied upon the enlargement of the post-auricular glands as a means of distinguishing rötheln from true measles.

Dr. Garber, in closing the discussion, said that his statement regarding the common recurrence of measles had referred to true measles and not to rötheln, as he had taken for granted that all physicians recognized these as two distinct affections, and were competent to differentiate them.

The Pathology of Pertussis.—Dr. J. M. Postle, of Hinckley, Ind., presented this subject. He believed the disease to be a toxic neurosis, produced by a bacterium, probably that which Koplik and others had constantly found in the expectoration. He believed that these bacteria worked in the mucous membrane, primarily of the upper respiratory tract, and passed down secondarily into the primary bronchi and alveoli. They produced a toxin which attacked by preference those nerve cells which governed expiration. This toxin was supposed to produce nerve depression, and consequently a clonic spasm of the respiratory muscles. The excess of carbonic acid in the blood produced a powerful stimulation of the nerve cells governing respiration, and at the same time almost completely destroyed the toxin. The cells returned very promptly to their normal condition after this destruction of the toxin. Immunization and recovery took place in about four weeks under appropriate medication. Remedies which powerfully stimulated the respiratory centres should be selected. The use of suprarenal gland hypodermically or by the stomach would materially assist. Strychnine, or some preparation of nux vomica, would give prompt and decided results if pushed almost, if not quite, to slightly toxic effects. This medication would completely relieve the vomiting, and if the remedy were stopped there would be almost no paroxysms of coughing for a period of about forty-eight hours.

Dr. Douglas, of Detroit, asked as to how large an experience formed the basis of this recommendation of strychnine.

Dr. Garber replied that he had used it in about fifty cases in a period of three years, and it had yielded positively favorable results in every instance. Medical friends had also given the method a trial, with the same result.

Dr. Slegle, of Minneapolis, said that he thought the physician had less control over pertussis than over almost any other of the common diseases. The use of strychnine was old, and he could not understand how it could be given so heroically in country practice without a good deal of risk.

Antenatal Treatment of Hæmophilia.—Dr. J. W. Ballantyne, of Edinburgh, Scotland, sent a communication on this subject, which was read by the secretary. In it he reported a case which seemed to indicate the possibility of one's being able, by the administration to a hæmophilic mother, during gestation, of chloride of calcium, not only to save her from severe hemorrhages at the time of confinement, but also to prevent the child when born from becoming a hæmophiliac. As he very properly admitted, the case reported might certainly be only a concidence, but the history was given in minute detail, and was, to say the least, suggestive.

Drs. Slegle and Clifton Scott were disposed to consider the author's position a reasonable one, and commended the scientific spirit of the communication.

Report of a Case of a Child who Ate Paint, Wood, and Plaster.—Dr. Brownell, of Oneonta, N. Y., made this report. The child was ten months old, apparently of normal intelligence. Both it and its parents were healthy. The child ate these strange things whenever an opportunity presented itself. Suddenly, after a long period of obstipation, it died in a convulsion. The autopsy showed three intussusceptions, but no inflammation and no lesions which would throw any light on the case.

Second Day—Wednesday, June 5th.

The special order for this session was a symposium on typhoid fever.

Symptoms and Course of Typhoid Fever.—Dr. J. P Crozer Griffith, of Philadelphia, was the author of this paper. He stated that it could not be denied that typhoid fever was a disease which one having much to do with disease of children must encounter quite frequently. The great degree of malaise and fatigue seen in the adult was usually absent in children. It was common for the child to be brought to the dispensary complaining of loss of appetite and headache, and the physician was usually the first to observe that it had any fever. Usually after careful observation for several days the diagnosis of typhoid fever was made, chiefly by exclusion. Of course, in some cases the onset was sudden and marked; in others the suddenness was only apparent, the earlier symptoms having been overlooked. Very frequently only the serum reaction would distinguish the case from one of indigestion or of enteritis or of an attack of influenza. The average duration was about seventeen days, though abortive attacks were quite common. The mortality in children was from three to five per cent., being nearer the latter than the former. The typhoid roseola was nearly as frequently present as in adult life, according to the experience of many observers. In a very few cases he had seen herpes labialis develop. French observers had described desquamation as of not infrequent occurrence. Enlargement of the spleen was probably always present, and could usually be detected on careful examination if the abdomen were not too much distended. Epistaxis was probably nearly as frequent as in adult life. The temperature ran a similar course to that observed in adults, though it was subject to greater variations, and often remained for a considerable time at the maximum. The remittent type of temperature seen in the later stages of typhoid in the adult was not so common in children. Vomiting was much more frequent than in later life, and even in advanced cases was often a troublesome symptom, and, indeed, he had known it to be the cause of death. Abdominal tenderness and distention were usually not marked. Intestinal hemorrhage was exceedingly rare, and when it did occur it was usually in children eight or ten years of age. One of the characteristics of typhoid fever in children was the tendency of the nervous symptoms to predominate over the intestinal symptoms. A certain degree of apathy was a common feature, especially in young children. The condition known as pseudo-meningitis was apt to cause confusion in the diagnosis. He had seen typhoid fever begin in children with all the symptoms of an acute leptomeningitis.

The Diagnosis of Typhoid Fever in the Laboratory.—Dr. John Lovett Morse, of Boston, Mass., sent this communication, which was read in his absence. The author said that the chief laboratory tests for typhoid fever were the Widal reaction, the examination of the urine and fæces for typhoid bacilli, the examination of the blood and of the rose spots for these bacilli, the diazo reaction in the urine, and finally the leucocyte count. The Widal reaction was observed in ninety-five per cent. of all cases, and was not usually observed before the second week. In a small number of cases it was never present; in others, it was present only intermittently; hence, typhoid fever could not be excluded even by repeated negative tests for this reaction, though the latter constituted extremely strong evidence of typhoid. The reaction might be obtained from the blood after the lapse of twenty-one years; hence, a positive reaction in persons who had had typhoid fever previously was not absolute evidence of the present illness being typhoid. The occurrence, however, of a positive after a negative reaction in a dilution of one in fifty should be looked upon as positive evidence of the presence of typhoid fever. The presence of the Widal reaction in early infancy was of less diagnostic value than in later life because the agglutinating power might be transmitted

from the mother to the fœtus through the placenta. It was also probable that it might be transmitted through the breast milk for years, but when so transmitted it did not persist for more than one week. Although typhoid bacilli were usually present in the stools before the Widal reaction was obtainable from the blood, it was a much more difficult test to apply, requiring laboratory facilities and expert knowledge. Typhoid bacilli could be found in the urine in from twenty-five to thirty per cent. at some stage of the typhoid. In a few cases only had they been demonstrated in the urine before the Widal reaction. The isolation of the bacilli from the urine was less difficult than from the stools, requiring only about two days. Typhoid bacilli had also been cultivated from the splenic blood obtained by puncture of the spleen, but this was not justifiable. It had also been obtained from the blood from a vein in eighty per cent. of the cases examined. This test also required expert knowledge, and two days for its performance. Tapping of the vein was a much more delicate and risky procedure than pricking of the ear. By excision of several rose spots under aseptic precautions typhoid bacilli had been isolated, but the method was not available for the general practitioner. The diazo reaction could be obtained in the urine of most cases of typhoid fever, and quite early in the disease, but as it was present in several other diseases liable to be confounded with typhoid fever, its diagnostic value was not very great. The leucocyte count was subnormal throughout typhoid fever, the average number being 5,000 per cubic millimetre. This count was of no value in the differential diagnosis between typhoid fever and malaria, neither of which had a leucocytosis. On the other hand, it was of great value in differentiating between typhoid and septicæmia, because of the occurrence of leucocytosis in the latter and its absence in the former. The increase in the number of white blood corpuscles in typhoid fever meant some complication, often an actual or a threatened perforation of the bowel. The examination of the blood for the malarial plasmodium to distinguish typhoid fever from malaria, and the examination by lumbar puncture to differentiate the disease from meningitis, were both important tests. In conclusion, the author insisted that the Widal reaction and the leucocyte count were of the greatest value as practical tests, and that all laboratory tests should be used in conjunction with clinical study.

The Treatment of Elevated Temperature by Drugs.—Dr. Edwin Rosenthal, of Philadelphia, read this paper. He said that typhoid fever was probably the only disease in which the temperature was higher in adults than in children. The temperature might range from 101° to 106° without any unusual disturbance. The average duration of the fever in young children was about eighteen days. After having used many drugs he had come to the conclusion that none acted specifically in the control of the fever. He had tried a number of the coal-tar derivatives, but had not observed any positive results from them. He was disposed to use in uncomplicated cases of typhoid fever the "neutral mixture" of the pharmacopœia. He had tried many of the so-called specifics. It should be remembered that hyperpyrexia produced tissue degeneration, and was more apt to do this in children than in adults. He preferred bathing by tubbing or sponging to drugs for controlling a dangerous degree of fever.

A Case of Multiple Gangrene, Associated with Cholangitis and Adenoma of the Liver, Complicating Typhoid Fever.—Dr. Isaac A. Abt, of Chicago, reported this case. The subject of it was a female child of twenty-one months, who had come under observation on the fourth day of her illness, or on September 25, 1900. Four days previously the illness had begun with headache and fever, and she was already dull and listless. At the same time the father was in a ward of the same hospital with well-marked typhoid. The temperature on admission had been 103°, the pulse 130, and the respirations 28. The Widal reaction was positive. There was a peculiar eruption on the head, back, and extremities. It began as papules, which soon became pustular, and then these resulted in the development of areas of gangrene. The child became steadily weaker, and died on October 12th. The process had been most marked on the back, where there had been an area as large as a quarter. At the autopsy the liver was found somewhat enlarged, reddish, and firm. Its surface was studded with pin-point areas having a reddish centre and a yellowish periphery. In the inferior portions of the left lobe was an area, about the size of a lemon, having a white fibrous and nodular appearance. The Peyer's patches of the intestine were swollen, but presented no ulceration. Cultures made from the areas of gangrene showed the presence of staphylococcus pyogenes aureus, and cultures from the spleen showed a bacillus which resembled the typhoid bacillus, but its identity could not be definitely determined. Microscopical examination of the large fibrous area in the liver made it probable that it was an adenoma, and not a mere hyperplasia. There was, in addition, a round-cell inflammation around the bile passages, with a resulting necrosis of the liver cells. The report of the dermatologist who examined this case expressed the opinion that the process in the skin was a multiple embolic process leading to infectious multiple gangrene. This form of gangrene had been observed in connection with varicella, and had, therefore, been described by one author as varicella gangrenosa, but it had been found as a complication of a number of other disorders. The catarrhal form of cholangitis found in this case had received little attention in literature. The occurrence of adenoma in the liver of children was extremely rare.

Dr. Victor C. Vaughan, of Ann Arbor, Mich., opened the general discussion on typhoid fever in children. He said that he would explain the lesser frequency of this disease in children on the ground that children did not go about so much or drank water from so many different sources as adults. He was inclined to think that many persons, both adults and children, escaped with only a mild attack because there was a mixed infection, as a result of which the bowel was irritated by non-specific bacteria, and the diarrhœa thus set up carried out of the system most of the typhoid bacilli. This was more apt to happen in children than in adults because of the greater susceptibility of the mucous membrane of the bowel in children to irritation from such causes. Touching upon the death rate, the speaker said that in Hamburg, where every case of typhoid was reported as well as every death, out of about thirteen thousand cases the death rate was 7.5 per cent. He had calculated the death rate in the hospitals of this country from statistics of several thousand cases, and had found it to be between eight and nine per cent. According to the statistics of the health department of New York City, however, the death rate from typhoid in that city was about twenty-nine per cent., while from similar sources the death rate in Philadelphia is computed to be about thirteen per cent. These great discrepancies were to be explained only by the supposition that New York physicians did not recognize and report many cases of typhoid. He had collected twenty thousand cases occurring in this country in private practice, and the mortality in this series was about sixteen per cent.

Dr. Charles Douglas, of Detroit, said that he had often seen the fever increase and the patient made uncomfortable by an improper dietary. He would give

anything which was easily digested, usually milk, broths, and white of egg, and he would never give more than one pint for every fifty pounds of body weight.

Dr. T. F. Wood, of Angola, Ind., corroborated the statements of the last speaker regarding the common error of feeding typhoid patients too much, and giving them too little water. It was well to keep the bowels slightly relaxed. When the fever was dangerously high, it should be controlled by systematic bathing. Absolute rest and quiet were most important.

Dr. Barber, of Minneapolis, described an epidemic of typhoid that had occurred in his city from infection of the water supply, and pointed out that whereas in the early part of the epidemic, when the level of the river was low and there was much ice present, most of the cases of typhoid had been very severe, in the latter part of this epidemic, or when the river had been replenished by copious rains, sixty per cent. of the cases had been exceedingly mild, being of the walking type. He raised the question as to whether this change to a milder type had been the result of the dilution of the infected water in the river, or to an actual decrease in the virulence of the bacilli.

Dr. Johnston, of Grand Rapids, Mich., said that the physicians of his city had been the pioneers there in using the bath treatment for typhoid fever; and now, after ten years, he wished to assert most positively that the method was entirely applicable to cases in the country and in private practice, as well as to those treated in the large metropolitan hospitals.

Dr. George D. Head, of Minneapolis, said that he wished to protest against the prevalent notion that the white blood count was not a reliable diagnostic method in children. While the Widal reaction often appeared too late to be of any practical value in making the diagnosis, the leucocyte count was often of great assistance in this respect from the beginning.

Dr. Rosenthal, in closing, said that if after two weeks the typhoid diarrhœa gave place to constipation, showing that the disease was held in check, he would not then think of giving calomel, as this, by causing irritation of the bowel, would almost surely do harm.

Prolonged Intubations.—Dr. Edwin Rosenthal, of Philadelphia, was the author of this paper also. He said that whereas formerly the practice of O'Dwyer and his followers had been to leave the tube in the larynx for seven days before attempting its removal, it was now known that this period had been reduced by the use of diphtheria antitoxin, so that the general rule at present was to remove the tube, in uncomplicated cases of diphtheritic stenosis of the larynx, in five days. The author divided the causes of prolonged intubation as follows: (1) the type of the disease; (2) the result or sequela of the disease; and (3) the wearing of the tube. By far the most frequent cause was the second one mentioned, *i.e.*, the result of the disease, diphtheritic paralysis. The too free use of certain irritating medicaments, such as peroxide of hydrogen, to cleanse the tube he felt sure was one cause of prolonged intubation. Formerly he had made use of as strong solutions of peroxide of hydrogen as he could obtain; now he employed a very weak solution. The so-called solvents of the membrane should never be used. It was better and far safer to make use of a solution of borax. If antitoxin were used early enough, it would be found an effective prophylactic measure.

Dr. B. R. Shurley, of Detroit, was of the opinion that prolonged intubations should be considered to be those in which the tube was retained longer than the sixth day. It had been his practice to remove the tube on the fourth day, and sometimes even on the second day. It seemed to him that under a dosage of 3,000 units of antitoxin the tube might be safely removed on the fourth day, and would not ordinarily be required again. In his opinion, the most important cause of prolonged intubation was traumatism incident to the improper performance of intubation. The next most important etiological factor was the use of an ill-fitting tube. He objected to the use of plated tubes on the ground that the plating was liable to be worn off, and wherever there was a defect in it calcareous deposits were apt to form, and so cause injury to the delicate mucous membrane of the larynx.

Dr. Golden, of Chicago, said that in a few rather mild cases of stenosis of the larynx he had administered internally two grains of suprarenal extract at intervals of three hours. This had caused such prompt subsidence of the œdema and disappearance of the symptoms that he had even had the parents refuse to allow intubation to be performed, claiming that it was no longer required.

Dr. I. A. Abt, of Chicago, thought it was an excellent practice to intubate every day, or even more often, beginning about twenty-four hours after injection. This should be possible if the dose of antitoxin had been sufficiently large. He was convinced that there were a few cases in which intubation was impossible. One such case was reported in which it had been impossible even just after death to insert the tube into the larynx.

Dr. Rosenthal, in closing, said that he employed plated tubes, but always had them regilt after each using. This could be done at a cost of seventy-five cents, and should be done after each insertion of the tube, even though it was reinserted in the same case a number of times.

Prevention of Pulmonary Tuberculosis in Predisposed Children.—Dr. John A. Robison, of Chicago, read this paper. He made a plea for considering heredity as well as the tubercle bacilli, particularly when statistics showed that heredity played a part in no less than thirty-six per cent. of the cases. A child might inherit scrofula without the bacillus, or the bacillus without scrofula, or, as was most commonly the case, both together. Children of tuberculous parents were easily infected either directly or indirectly. As Holmes remarked, prevention should begin with the ancestors. The great aim of the physician in the management of children predisposed to tuberculosis should be to promote nutrition. The baby should never be nursed by the mother, but by a wetnurse, or else fed with food known to be positively free from the tubercle bacillus. The effort should be made early to encourage a taste for fats, and the natural craving for sweets should not be too strictly curbed. In his opinion, candy was rather beneficial if given after and not between meals. Water should also be given freely. During childhood the diet should contain a greater proportion of nitrogenous food, for nitrogen supplied muscular force. The period of puberty was a critical one. Enforced ignorance of the sexual laws was most harmful. We boasted of our public schools, yet the method of class instruction there in vogue, subjecting as they did the strong and weak to the same strain, did a great deal toward wrecking feeble constitutions. The harmonious and dual development of the mind and body must be secured. After the period of education came the selection of a vocation. An open-air occupation requiring the person to be active was the best. Work in crowded factories or in dusty places should be sedulously avoided. The statistics in this country showed that the lowest mortality was among farmers. Contrary to what might be expected, the mortality was very low among coal-miners. These persons predisposed to tuberculosis should be warmly clad, and the clothing should be loose enough to allow of free exercise. A corset should not be worn by such a child, as it interfered with nutrition and the development of the re-

spiratory function of the lungs. Excessive swaddling of the neck and chest should also be avoided, as this made these parts unnecessarily sensitive to changes in temperature. The predisposed should avoid contact as far as possible with persons who were consumptives. Hydrotherapy was of great value, as it stimulated the nutritive processes and steadied the vasomotor nerves, thus diminishing the susceptibility to changes in temperature. Fresh-air sanatoria and the country vacation clubs were doing a great deal of good by lessening the susceptibility to consumption in our midst, but their work was far too restricted. France beat the rest of the world in its provision of sanatoria for the care of children who were tuberculous or predisposed to this disease. The physician should warn parents concerning the danger of measles, whooping-cough, tonsillitis, and adenoids in these children.

Dr. T. F. Wood, of Angola, Ind., said that the author of this admirable paper had left out of consideration a most important underlying cause, the lack of any proper restrictions on the marriage of tuberculous individuals.

Dr. Work, of Elkhart, Ind., thought the physician should give explicit directions not only regarding the kind and quantity of clothing to be worn, but should insist that it be changed in accordance with the sudden and marked changes in our climate.

Dr. Slegle, of Minneapolis, recalled the fact that Professor Flint used to lay great stress on the general aversion to fats exhibited by tuberculous persons, and added that he thought it most important that such persons should be taught from the earliest childhood to eat fats freely.

Dr. Johnston, of Grand Rapids, quoted certain statistics published in Virchow's *Archiv*, showing that ninety-eight per cent. of the human race who attained the age of thirty exhibited post-mortem lesions of tuberculosis, and that, therefore, it was evident that almost every one must be infected with the disease at some time. Osler maintained that there were only twenty cases on record of persons having been born with the disease. The system of reporting cases of tuberculosis in the State of Michigan was commended, and it was asserted that as a result of this in the last eight years the death rate from pulmonary tuberculosis in that State had been reduced from one hundred and twenty to ninety per ten thousand of the population.

Dr. Kelsey, of Minneapolis, said that he thought some of the credit for the improved conditions existing in Michigan should be given to advances in hygiene.

Protracted Influenzal Pheumonia in Children.—Dr. F. X. Walls, of Chicago, presented a paper on this subject, based on a clinical study of four cases. Attention was called to the sudden onset and the great height and marked daily variations in temperature. Distinct crepitant râles had been wanting over the consolidated area. Two of the four patients recovered after twenty-five and forty-one days respectively; the other two died. The differential diagnosis included gastro-intestinal infections, pneumococcus pneumonia, ordinary broncho-pneumonia, malaria, sepsis, and tuberculosis. These cases should be isolated in a room having a temperature of 80° to 85°.

Dr. I. A. Abt, of Chicago, said that all protracted pneumonias were not due to influenza. The greatest difficulty he had experienced in these cases had been to differentiate an empyema with a limited quantity of fluid from cases of protracted pneumonia of whatever type.

Congenital Malformations with Roentgen Ray Demonstrations.—Dr. Carl Beck, of New York, read this paper, and exhibited many photographs and radiographs.

Membranous Colitis in Infants.—Dr. Charles Douglas, of Detroit, was the author of this paper. He said that this disorder commonly appeared suddenly, and was accompanied by vomiting, high fever, severe pain, and frequent, large mucous stools. The stools resembled those of catarrhal enteritis except that they contained more blood and also the characteristic yellowish opaque masses of membrane. The prognosis depended upon the amount of mucous discharge and the duration of the illness. Recovery usually took place in eight or ten days. The disease was rare in infants under six months of age, and was most apt to appear in hand-fed infants. Three cases were reported occurring in very young infants, and presenting some unusual symptoms.

A Case of Ureteral Calculus in a Boy of Ten.—Dr. W. W. Keen, of Philadelphia, reported this case, and presented an excellent skiagraph of the same, made by Dr. Leonard. This child gave a history of numerous attacks of nephritic colic from the age of two years. Because of the distention and extreme tenderness, the calculus, which was evidently present on the left side, could not be located until a radiograph had been taken. At the operation, which was done on October 2, 1900, under the guidance of the skiagraph, a calculus was found a little below the pelvic brim in the left ureter. The stone measured 1.5 cm. by 1 cm. by 8 mm. Its nucleus was mucin, and the shell was composed chiefly of calcium phosphate. The recovery was uneventful. In the opinion of Dr. Keen this was one of the most remarkable demonstrations of the value of skiagraphy in such obscure cases.

Dr. Leonard, of Philadelphia, said that he had found a calculus in forty-seven cases examined by skiagraphy, and in fifty per cent. of them the calculus had been lodged in the ureter. As this method placed the surgeon in complete control of the situation, it was rational to resort to expectant treatment in certain cases.

Dr. Clifton Scott, of Des Moines, spoke of the negative as well as the positive value of the method in preventing useless operations founded on erroneous diagnoses.

Third Day—Thursday, June 6th.

Diabetes Mellitus in Children.—Dr. A. C. Cotton, of Chicago, read this paper and reported a case. He said there could be little doubt that this disease was apparently on the increase, but this might perhaps be explained by the greater number of cases reported in consequence of improved diagnosis. Dr. Stern's statistics were quoted to show that the annual average of cases reported to the bureau of vital statistics of New York City was one hundred and sixty-eight, and that the figures for Chicago, from a similar source, were one hundred and four. It seemed to him clear that heredity played a distinct part in the etiology. He did not accept the view entertained by some, that there was a causal relation between diabetes mellitus in children and the acute infectious diseases. The glycogen-storage capacity of the tissues of children had been found to be relatively high. Since the obese type was practically unknown in children, an advanced case of diabetes in early life presented a picture of extreme malnutrition. The affection was essentially acute in childhood, few cases surviving more than a few months. With the exception of opium and the alkalies, the benefits of drug therapy were admittedly very small. The death certificate usually followed hard upon the diagnosis. Something might, however, be accomplished in the way of prophylaxis by guarding these children against dietary indiscretions and against nervous shock and traumatism. Success in the treatment was in inverse ratio to the duration of the disease; hence the great importance of an early diagnosis. He believed too much stress could not be laid

upon the importance of protecting these children from sudden lowering of temperature.

Albuminuria in Disease of the Kidneys in Infancy and Childhood.—Dr. John R. Rathmell, of Chattanooga, Tenn., was the author of this paper. He said that even in so-called cases of functional or cyclic albuminuria it was probable that slight changes took place in the kidney. For cases of albuminuria an almost exclusive diet of milk was the treatment *par excellence*. The hot wet pack would be found an exceedingly useful therapeutic measure. When there was much œdema, cathartics were especially useful. Teaspoonful doses of infusion of digitalis, given every four hours, to a child of four years, would be found beneficial.

Congenital Cystic Kidney.—Dr. William Jepson, of Sioux City, Iowa, reported this case and exhibited the specimen. The points of interest were: (1) The involvement of only one kidney; (2) the absence of disturbance until the cyst was of such a size as to cause undue pressure; (3) the fact that even inspection of the growth at the operation was not sufficient for a diagnosis until a number of other conditions had been excluded, and (4) the fact that this was believed to be the youngest patient to recover after a nephrectomy.

Gonorrhœa in Boys.—Dr. A. L. Wolbarst, of New York City, was the author of this communication. He had seen cases of gonorrhœa occurring in males varying in age from eighteen months to twelve years. The clinical diagnosis had been confirmed by microscopical examination. It was generally thought, he said, that in such young boys the disease arose from infection from soiled linen and filthy water-closets, but his experience with the children of the vile tenements had led him to believe that many such cases originated in the same way as in older persons. He had himself observed gonorrhœal urethritis in three boys of four, ten, and twelve years of age respectively, and in girls of ten and twelve years. The social conditions of the tenement dwellers accounted for very early sexual relations. In this class pæderasty was not uncommon. In accordance with a superstition brought over to this country from certain parts of Europe, some prostitutes endeavored to rid themselves of gonorrhœa by endeavoring to convey it to a child. In these very young children affected with gonorrhœa there was usually frequent and burning micturition, but often also nearly complete retention. The discharge differed from the beginning very little from that seen in the adult. The pain which these children suffered was usually out of all proportion to the symptoms, but this was explicable by the existence of a tight prepuce. Many of these children would not be brought to the surgeon if it were not for the great redness and swelling of the prepuce. These cases afforded ground for an earnest plea for the circumcision of all male infants. Posterior urethritis, prostatitis, and even epididymitis occurred in these cases. When the prostate was involved, it became swollen and highly sensitive, causing intense pain on defecation. It was interesting to note that the duration of the disease, four to six weeks, was the same as in adults, yet there was not the same tendency to development of chronic urethritis as in adults. Physicians practising among the poor should see to it that healthy children did not sleep with infected ones, and that they be warned of the danger of disseminating the disease. The primary requisite in treatment was cleanliness, even carried to the surgical degree. This would in itself often prevent disagreeable complications. If the child had been circumcised, the use of warm water or of boric acid several times a day would secure this. If the prepuce were tight, the cleansing solution might be injected between the prepuce and the glans penis. For the anterior urethra the injection of a half-per-cent. solution of protargol, three times a day, and the retention of this for several minutes each time, would often prove wonderfully effective. In spite of this treatment, or perhaps because of it, the inflammation might extend to the posterior urethra. Irrigation of the urethra with a solution of potassium permanganate, 1:6,000, would prove very beneficial. It was best done with a small soft catheter, or with a small glass syringe. After the bladder had been well filled with the solution, the latter should be urinated out and the injection repeated. The internal administration of pure oil of wintergreen in doses of ♏ v. to x. in milk or water, three times a day, would prove of benefit. Epididymitis was best treated by the local application of a ten-per-cent. guaiacol ointment. When the prostate was inflamed and very painful, rectal irrigation with hot water usually afforded relief. Small-sized "gonorrhœa bags" might be used with excellent effect to prevent further infection, especially of the eyes.

Dr. Edwin Rosenthal, of Philadelphia, said that he had known a whole troop of boys to be infected by one prostitute in the effort of the latter to rid herself of the disease.

The paper was quite extensively discussed, the speakers concurring in the author's view concerning the large number of children who were infected with gonorrhœa.

The Prevention of Infection in Babes Born of Tuberculous Parents.—Dr. Clifton Scott, of Des Moines, in this paper presented a brief report of two cases, one in which the mother, a primipara, had died of chronic pulmonary tuberculosis within six months after the birth of the child; another case in which the mother, also a primipara, had died of acute pulmonary tuberculosis within four months after the birth of her child, the latter dying of acute pulmonary tuberculosis one week after the mother's death. He asserted that many babies dying of hereditary tuberculosis were really infected.

Dr. Johnston, of Grand Rapids, remarked that these two cases had evidently been infected from the mother's sputum or from tuberculous milk.

Dr. Cook, of Chicago, narrated a case in which a young lady had become infected with tuberculosis from a pet monkey.

Dr. E. F. Brush, of Mount Vernon, N. Y., detailed an experiment that he had made, *i.e.*, the feeding of the tuberculous masses taken from a tuberculous cow to twenty-four laying hens and a rooster. All of the animals had died of tuberculosis within five or six weeks. Twenty-four eggs laid by these hens had been set under healthy hens in another part of the farm, and while all of these eggs developed a chick, every one of them was dead. He had known seven healthy children to be reared on the raw milk from a cow subsequently found to have been tuberculous for a long time. It was necessary, therefore, to have some other element in addition to the tubercle bacilli, probably an elevation of temperature.

The following papers were read as parts of a symposium on school hygiene:

The Introduction and Management of School Hygiene.—Dr. Leigh K. Baker, of Cleveland, Ohio, in this paper described a general plan of organization.

Physical Culture in Children, and the Objects to be Attained.—Dr. John Madison Taylor, of Philadelphia, said that the first object of physical culture was to enable the children to assume and maintain a proper and normal attitude. The throwing back of the shoulders according to the old military position was wholly artificial, and tended to impair the equipoise. The shoulders should be let alone, and should be free from tension, but the back should be kept straight and the abdomen held in. The position of the pelvis should be maintained as nearly at a level as possible

so that movement along the level would be almost unconsciously performed. Properly executed breathing exercises were of importance.

The Pubescent School Girl. — Dr. William E. Darnell, of Atlantic City, N. J., read this paper. The importance of this subject was considered to be especially great in this country because of our high-pressure system of education. The strain was bad enough in growing boys, but girls must not only keep up with their classes but must spend many weary hours in the study of music and other accomplishments. After graduation these brain-fagged and physically incapacitated girls plunged into a life of social gayety and dissipation, and little or no attention was given to securing rest at the menstrual period.

Diagnosis of the Backward Child.—Dr. A. W. Wilmarth, of Chippewa Falls, Wis., read this paper. He said that there was no sharp line of distinction between the normal and the backward child, and often there seemed to be some relation between mental backwardness and moral obliquity. The hope was expressed that more special schools for this class of children would be provided.

Speech as a Factor in the Diagnosis of the Backward Child.—Dr. G. Hudson Makuen, of Philadelphia, presented this paper. He gave as a scientific definition of the backward child, "one who is not living up to his capabilities or possibilities." Freedom of speech, he said, was an absolute essential to the normal development of children, and any impairment of this function would unfavorably influence the mental development, for speech was a tool of the mind. It was not always possible to determine at a glance the cause of the backwardness. The latter was not always due to a central lesion, but to an arrest of development or some abnormality of structure in the peripheral organs. Often a defect of the organs of speech was to blame. The best method of arriving at even an approximately correct prognosis was to apply the speech test, *i.e.*, to ascertain by careful study and experiment to what extent the faculty of speech could be improved. Those who were susceptible to training in the refinements of speech were the ones in whom the best results could be promised.

A Plea for the Backward Child.—Dr. C. F. Wahrer, of Fort Madison, Iowa, read this paper. He said that many geniuses had been considered dull and stupid in childhood, but their apparent backwardness had been simply the result of the mental powers being latent. To discover and guide, and not condemn, the backward child should be the effort of all.

Some of the Considerations Regarding the Medical Criticisms of the Hygiene of Early Life.—Dr. J. Noer, of Stoughton, Wis., presented this paper. He pointed out the absurdity of the contention of the pedagogists that they should have the absolute control of the children, for, while no doubt the details of instruction must and should be left to them, the position which they took was comparable to that of a physician who would claim that he had absolute control of the children under his care, and could treat them regardless of their wishes or those of their parents.

Officers Elected.—*Chairman*, Dr. H. F. McClanahan, of Omaha; *Secretary*, Dr. Frank X. Walls, of Chicago.

Electric Light Least Injurious to the Eyes.—An English journal named *The People* has the following item of news: "A Russian medical man has decided that the electric light is least injurious to the eyes. He says that the oftener the lids are closed the greater the fatigue and consequent injury. By experiments he finds that the lid would close with different illuminations per minute: Candle light, 6.8; gas, 2.8; sun, 2.2; electric light, 1.8.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 1, 1901:

	Cases.	Deaths.
Tuberculosis	226	152
Typhoid fever	30	5
Scarlet fever	449	30
Measles	302	13
Diphtheria and croup	241	48
Smallpox	86	16
Chickenpox	76	0

An Old-Time Physician on the Properties of Coffee.—M. Louis Lemery, "Regent Doctor of the Faculty of Physick at Paris," who lived in the first years of the eighteenth century, in a treatise he wrote upon foods, has this to say of the properties of coffee: "It fortifies the stomach and brain, promotes digestion, allays the headache, suppresses the fumes caused by wine or other liquors; promotes urine and women's terms, opens some people's bodies, makes the memory and fancy more quick, and people that drink it brisk. It agrees, when moderately taken, especially in cold weather, with old people; with such as are phlegmatic, and those who are fat and corpulent; but 'tis not so proper for bilious and melancholy persons. The use of coffee to excess is at least as pernicious as the moderate use of it is wholesome to many persons. Many persons that have been used to drink too much coffee become infirm and paralytic, as Willis and other physicians have observed."

The Teeth and Growth of Children.—At a recent meeting of the Harveian Society Dr. W. H. Dolamoret read a paper in which he pointed out the importance of the first set of teeth, both in regard to health and growth. He first showed how injurious an effect upon the health of the child might be produced by the septic condition of the mouth induced by caries of deciduous set of teeth. Among other conditions he mentioned ulcerative stomachs, necrosis of bone and enlarged lymphatic glands, which latter might become the seat of tuberculous growth, by which the whole system might become infected. He also traced much gastric disturbance to the same cause. Then he insisted on the important part played by the first teeth in regard to the growth of the child, and he concluded that the mastication of food could not be interfered with by the decay and extraction of deciduous teeth without impairing the health of the child.

Registrar-General's Report for Great Britain for 1899.—This report, says *The Medical Magazine*, contains very many points not only of statistical value, but of general interest. The estimated population of England and Wales in the middle of 1899 is put at 31,742,588 persons. The marriage act of 1898 came into operation during the year, and appears to have been attended with good results, for the marriage rate recorded, 16.5 per 1,000, is the highest reached since 1876, or 1.1 above the mean rate for the previous ten years. The marriage rate has increased of late years *pari passu* with an increase of value per head of the United Kingdom in exports of British produce and imports, showing the tendency of marriage to follow the lead of increase in natural prosperity. It is sad to note the still falling birth rate, which stands at 29.3 per 1,000, or 0.1 per 1,000 below the rate for the previous year and 1.0 below the mean rate for the previous ten years. There is a faint ray of hope held

out that, the rate being based upon a purely provisional population, the estimate may be fallacious. Its steady decrease of late years, however, has led thinking people to have grave apprehensions for the future of the empire, and to wonder whether the nation is not drifting into the state of the people alluded to by the psalmist when he wrote: "They have children at their desire." The death rate was 18.3 per 1,000, as against 18.4, the average of the previous ten years, and the various factors in this death rate were as follows: Infantile mortality was equal to a rate of 16.3 per 1,000, higher than the average of the ten preceding years. This represents in part the price paid by northern manufacturing towns for their factory labor.

Health Reports.—The following cases of smallpox, yellow fever, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended June 8, 1901:

		Cases.	Deaths.
Smallpox—United States and Insular.			
California, Los Angeles	May 18th to 25th	1	
San Francisco	May 18th to 25th	5	
Dist. of Columbia, Washington	May 25th to June 1st	1	
Illinois, Chicago	May 25th to June 1st	7	
Iowa, Ottumwa	April 27th to June 1st	16	
Kansas, Leavenworth	May 1st to 31st	3	
Wichita	May 18th to June 1st	42	
Louisiana, New Orleans	May 25th to June 1st	4	
Massachusetts, Boston	May 25th to June 1st	1	
Fitchburg	May 17th to 24th	1	
New Bedford	May 25th to June 1st	1	
Quincy	May 25th to June 1st	1	
Michigan, Detroit	May 25th to June 1st	57	
Grand Rapids	May 25th to June 1st	2	
Minnesota, Minneapolis	May 18th to June 4th	15	
Winona	May 25th to June 1st	1	
Missouri, St. Louis	May 19th to 26th	27	
Nebraska, Nebraska City	April 27th to May 18th	6	
Omaha	May 17th to June 1st	25	
South Omaha	May 24th to 31st	26	
N. Hampshire, Manchester	May 25th to June 1st	7	
N. Jersey, Jersey City	May 26th to June 2d	4	
Newark	May 25th to June 1st	2	
New York, New York	May 25th to June 1st	64	17
North Carolina, Charlotte	May 1st to 31st	11	
Ohio, Cincinnati	May 1st to 31st	10	
Cleveland	May 25th to June 1st	31	1
Youngstown	May 18th to 25th	1	
Pennsylvania, Lebanon	May 23d to 31st	5	
Philadelphia	May 25th to June 1st	4	
Pittsburg	May 18th to June 1st	7	
Rhode Island, Providence	May 25th to June 1st	1	
Warwick	May 23d to 30th	1	
Tennessee, Memphis	May 25th to June 1st	13	
Nashville	May 25th to June 1st	6	
W. Virginia, Green Bay	May 26th to June 2d	4	
Milwaukee	May 25th to June 1st	2	
Utah, Salt Lake City	May 18th to June 1st	19	1
Washington, Aberdeen	May 21st	4	
Smallpox—Foreign.			
Argentina, Buenos Ayres	March 1st to 31st	76	
Austria, Prague	May 11th to 18th	5	
Belgium, Antwerp	May 6th to 11th	7	2
Ceylon, Colombo	April 20th	1	1
Colombia, Panama	May 20th to 27th	6	
France, Paris	May 11th to 18th	..	15
Great Britain, Glasgow	May 11th to 18th	..	3
Nottingham	May 16th	1*	
Italy, Naples	May 3d to 10th	114	25
India, Bombay	April 23d to May 7th	..	12
Calcutta	April 20th to May 4th	..	125
Karachi	April 21st to 28th	8	5
Madras	April 20th to May 3d	..	28
Russia, Moscow	May 4th to 18th	29	13
Odessa	May 4th to 11th	5	1
Warsaw	April 29th to May 4th	..	1
Switzerland, Geneva	May 4th to 11th	1	
Yellow Fever.			
Costa Rica, Liberia	May 25th	Present.	
Cholera.			
India, Bombay	April 22d to May 7th	..	4
Calcutta	April 20th to May 4th	..	126
Madras	April 20th to May 3d	..	7
Plague.			
Africa, Cape Town	To April 27th	377	160
India, Bombay	April 22d to May 7th	..	778
Calcutta	April 20th to May 4th	..	371
Karachi	April 21st to 28th	273	233

* Apparently transmitted from Salt Lake City, Utah, by fomites.

Lunacy Statistics.—Finland, says an English weekly journal, turns the tables on England in lunacy statistics. Out of a million Finns, 1,700 only are fit subjects for the lunatic asylum. No part of England drops below 2,500. London heads the list with 3,610 mad persons in each of her 5,000,000. Harder-headed Scotland has 2,580 in 1,000,000.

Antiseptic Barber Shops in Paris.—Several barbers in Paris, says *The Scientific American*, have been induced by medical students to introduce aseptic hair dressing. In front of each chair there is a gas burner, metal combs are used, and they are passed through the flame several times. Scissors and razors are likewise purified by fire. The brush cannot, of course, be treated in this manner, but it is given a frequent wash in an antiseptic solution, in which thymol is the principal ingredient. The principles of the operating-room of the hospital are thus extended to the barber shop, and as the barbers used formerly to be surgeons as well, they should be flattered if they are required to observe the practice of surgeons to-day.

A Helper of the Deaf.—The Rev. Dr. Thomas Gallaudet, says the New York *Tribune*, May 26th, will be seventy-nine years old if he lives until June 3d. He has spent a great portion of his life in efforts to promote the welfare of deaf-mutes. His father founded the first permanent school for deaf-mutes at Hartford, Conn., in 1817. In October, 1872, Dr. Gallaudet founded the Church Mission for Deaf-Mutes, having for its object the promoting of the welfare of the silent people after leaving school. This society was a pioneer in church work among deaf-mutes throughout the country. It has a board of twenty-five trustees, with the bishop of New York as president *ex officio*. Its missionaries hold services at ten places. The society has established the Gallaudet Home for Aged and Infirm Deaf-Mutes. Dr. Gallaudet has made several visits to Europe in the interests of work among the deaf-mutes.

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

CLINICAL ANNOTATIONS ON FIVE CASES OF RIGHT-SIDE ABDOMINAL DISEASE.[1]

BY A. A. BERG, M.D.,

NEW YORK,

ADJUNCT SURGEON TO MOUNT SINAI HOSPITAL.

I THOUGHT it would be of more interest to the majority of the members of this association to present for their consideration a clinical rather than a technical or theoretical subject. The trend of medicine and surgery of the present century will be toward perfecting our diagnostic methods and improving our therapeutic procedures, and we can further these ends only by rehearsing, reviewing, and discussing the cases that have come under our observation and treatment. These reasons constitute my apology for giving at length the clinical records of the following five cases. Outside of their intrinsic value all of them present features that are of interest from diagnostic and therapeutic standpoints. The histories are:

1st. Of a case of typhoid fever, with intestinal perforation; suture of the perforation; recovery.[2]

2d. Of a case of tuberculous purulent peritonitis; cœliotomy; recovery.

3d. Of a case of empyema of the gall bladder, with impacted stones in the cystic duct; cholecystostomy; recovery.

4th. Of a case of suppurative appendicitis, complicated with a large ovarian cyst and pyosalpinx; abdominal section, removal of the appendix, cyst, and pus tubes; recovery.

5th. Of a case of lymphosarcoma of the intestine, simulating appendicitis; laparotomy; recovery from the operation.

Before proceeding to the recital of the individual cases, a few general remarks might be in place. All these patients were sent into the Mount Sinai Hospital,[3] by competent practitioners, with a diagnosis of appendicitis. In all the head and front of the disease appeared to be located in the right iliac fossa, and hence the errors in their diagnosis. I had occasion some time ago, in a communication published in the *Philadelphia Medical Journal*, May 20, 1898, on the "Differential Diagnosis of Appendicitis from other Affections in the Right Iliac and Pelvic Fossæ," to call attention to the frequent mistakes that are made in ascribing inflammatory diseases in these regions to the appendix. The causes of these rather frequent errors are to be sought, first, in the overwhelming frequency of appendicular as compared to other diseases in these parts of the abdomen, and secondly, in the close anatomical relation of the appendix to the other organs of the right side. While we should be able to guard ourselves against errors due to the first factor, by carefully excluding all the organs disease of which might simulate appendicitis, still frequent errors are bound to arise. Often a differential diagnosis is utterly impossible. A close investigation, however, into the antecedent history of the patient, combined with a carefully conducted abdominal, rectal, and, if the patient be a woman, vaginal examination, will render such errors very infrequent, and will serve to remove from the already overtaxed appendix a large part of its burden as a factor in diseases of the right side of the abdomen.

CASE II.—Tuberculous purulent peritonitis in a girl fourteen years of age; abdominal section; evacuation of the exudate, drainage, recovery.

Minnie R—— was admitted to the medical service of Dr. Manges, July 10, 1900. Her family and previous histories were negative. Four days before her admission she had a chill and severe headache, and vomited twice; the stools were soft and black. The headache and vomiting ceased after two days, but she commenced to complain of pain in the right iliac fossa. The pain remained local for two hours, and then became general over the abdomen. It was sharp and cutting. There was no chill subsequent to the one at the onset of the illness. Physical examination at the time of the child's admission showed her to be poorly nourished, her tongue moist, her expression anxious but not typhoidal; there was no eruption on the body; temperature, 103°; pulse, 124; respirations, 30. The heart and lungs were normal, likewise the liver and spleen. The abdomen was markedly distended and everywhere tender, but especially so in the right iliac fossa; the abdominal muscles were rigid and tense. There was dulness in both flanks, varying with change of posture. No obliteration of the liver or splenic flatness could be detected. Rectal examination revealed a slight fulness in Douglas' cul-de-sac. The pulse was small, not dicrotic. Blood examination showed no Widal reaction, but a leucocytosis of 25,000. Urine, negative.

On July 11th the temperature varied between 99° and 103°; the leucocytosis was more marked, being 36,000; the abdomen was more distended; the pulse was small and 104 to 124 to the minute; no Widal reaction was obtained.

July 12th. Resistance was felt in the right iliac fossa; leucocytosis about the same. There was some vaginal discharge, but no gonococci could be found in it. The diagnosis of appendicitis with peritonitis being made, Dr. Gerster was asked to see the patient. Her extremely wretched general condition rendered so probable an immediate succumbing from the shock attending a laparotomy, that delay was counselled until her general condition would become somewhat improved, and she be thus enabled better to withstand operative interference. The girl was therefore kept under expectant treatment, being freely stimulated the while. Two days later her general condition had improved, the pulse was more regular and full, the temperature fluctuating between 99° and 102°. During the next four days her general condition continued to improve, although the local abdominal symptoms were but little changed. On July 18th, eight days after her admission, her general condition had so far bettered itself that she was considered able to undergo the necessary abdominal section. Accordingly, under

[1] Read before the Harlem Medical Association, November, 1900.

[2] The history of this case will be reported in a separate paper.

[3] These patients were all of them admitted to the service of Dr. Gerster, by whose courtesy I am enabled to report them.

eucaine, the writer opened the abdomen in the right iliac region, and a quart of thin, inodorous pus from the free peritoneal cavity was evacuated. Exploration showed the intestines to be completely matted together into one mass, which had been pressed over to the right side of the abdomen. The appendix could not be isolated or found. The visceral and parietal peritoneum was completely covered with grayish fibrin, and studded with millet-seed spots that resembled tubercles. Microscopical examination of the pus showed streptococci but no tubercle bacilli. The peritoneal cavity was drained by tube and gauze.

Subsequent history: The child reacted well from the operative attack; the pulse at once improved, the temperature elevations were only moderate, never beyond 100°. The general condition commenced to get better; the discharge through the tube was profuse for a time, but gradually became more serous, and finally ceased. On July 22d a severe cough developed, and examination of the chest revealed dulness at the left apex, with diminished voice and breathing. The cough remained a prominent symptom during the convalescence. Repeated examinations of the sputum showed no tubercle bacilli. The abdominal wound gradually closed by granulation; the general condition continued to improve, and the patient was discharged, cured, September 9th.

Remarks: Here was a patient who exhibited all the clinical signs of a diffuse suppurative peritonitis that seemed to take its origin from the right iliac region. As the uterine appendages and gall bladder were apparently normal, the appendix was justly considered the most probable cause of the inflammation of the peritoneum. The streptococcus infection which had been engrafted upon the tuberculous process had served to confuse the diagnosis, for this mixed infection gave rise to a leucocytosis, high septic temperatures, and rapid pulse rate. Very many of the cases of tuberculous peritonitis resemble in their local signs cases of appendicitis. Thus there is marked resistance and even an indefinite tumor to be felt in the right iliac fossa, owing to the small intestine when it has become matted together sagging into the right iliac fossa, because its mesentery is attached more to the right side of the abdomen. Pressure over the inflamed intestine lying in this place elicits greater pain than in other parts of the abdomen. Two cardinal symptoms of appendicitis, then, namely, tumor and pain and tenderness, are present. If now a mixed infection is engrafted on a tuberculous process, so that fever and rapid pulse and leucocytosis occur, it can well be seen how difficult the differential diagnosis becomes. Even in the absence of such a mixed infection a differential diagnosis is often very difficult, but the non-febrile character and the longer duration of the disease, the presence of tuberculous areas in other parts of the body, will aid one in arriving at the proper diagnosis.

You no doubt have noted, in the report of the history of this case, that operation was declined when the child was first seen, because of her wretched general condition. The question may at once be asked, Is anything to be gained by waiting in such cases, and does not an immediate operation hold out to these patients their only hope of salvation, in accordance with the law *ubi pus, ibi evacua*, and at once? This is an important question, and demands earnest consideration. Let us review the facts at our disposal. On the one hand is the necessary abdominal section, which must be performed for the evacuation of the pus; on the other hand is the element of chance that the peritoneal inflammation may localize itself, the patient's general condition and pulse consequently improve, and thus he be better able to withstand the shock of an operation. Which procedure holds out the greatest possibility for recovery?

Experience has shown that a recovery following an operation performed at a time when the patients are in an extremely wretched condition, is a great rarity. The usual result is collapse immediately following the operation, from which the patient never rallies. On the other hand, it has been repeatedly observed that such cases, when kept under opium and ice applications, improve markedly, the pulse becoming of better quality and of less rapidity. It has been customary to ascribe this improvement to a self-limitation of the inflammatory process of the peritoneum. If operation is undertaken at this time, the patients are far better able to withstand the shock, rally well from the attack, and very often recover. I feel convinced that far better results can be obtained in these most desperate cases of diffuse peritonitis, by resorting to free stimulation, administration of opium, and application of ice, and operation at a period when the pulse improves, than by immediate resort to operative interference with a view of following out the letter of the law "*ubi pus, ibi evacua.*"

Case III.—A case of empyema of the gall bladder in a woman of sixty, with impacted stones in the cystic duct; cholecystostomy; recovery.

Braune L——, sixty years old, entered the surgical service of Mount Sinai Hospital, May 11, 1900. Her previous personal history was negative except for rheumatic attacks and indefinite abdominal cramps. She had never been jaundiced. Three days before her admission she was suddenly seized with severe abdominal pain, most marked on the right side, accompanied by vomiting of stomach contents. Her bowels moved once the following day; the color of the stool had not been noticed.

Physical examination revealed a very obese woman, with labored, rapid, and wheezy respiration; pulse rate, 126; temperature, 100.6°, and marked general prostration. No icterus was present. The abdomen was markedly distended, and tender to pressure, especially in the right flank. No pain was felt on pressure over the liver or right hypochondriac region. In the right umbilical and iliac region was a marked resistance of the rectus muscle, and an indistinct tumor, surrounded above, below, and internally by coils of intestines. No free fluid could be discovered in the abdomen.

Heart: A distinct systolic murmur was heard at the apex.

Under local anæsthesia of eucaine, the abdomen was immediately opened by the writer, the incision being placed directly over the mass. This was so low down that the incision lay in the right iliac fossa, about two inches above and parallel to Poupart's ligament. When the peritoneal cavity was opened a few ounces of free sero-purulent fluid escaped; the intestines were found adherent to an inflammatory tumor, and covered by a large amount of fresh fibrin. After the free peritoneal cavity was protected by gauze compresses, the intestines were carefully separated from the mass, which proved to be a very much enlarged and distended gall bladder. This was isolated by compresses, evacuated of its sero-purulent contents by aspiration, incised, and two large stones, one of which was impacted in the orifice of the cystic duct, were removed. Bile flowed freely into the gall bladder when the impacted stone was removed. The gall bladder was drained by tube and gauze, the incision in it closed around the tube by a purse-string suture, the abdominal wound partly sutured, and an aseptic dressing applied.

Subsequent history: The patient reacted fairly well from the operation; bile flowed freely from the tube in the gall bladder. The hypostatic pneumonia cleared up. The wound healed kindly; the tube drainage was removed from the gall bladder on the tenth

day; bile continued to discharge from the fistula for six weeks, when the latter closed spontaneously.

Remarks: This case illustrates admirably the difficulties which may be encountered in the differential diagnosis of right-side abdominal disease. The tumor representing the gall bladder was situated not in the right hypochondrium, but low down in the iliac region, and was surrounded on all sides by coils of intestines. In the absence of jaundice, and of any history pointing to cholelithiasis, and with a tumor separated from the liver above, and occupying the right iliac fossa, an accurate diagnosis was utterly impossible. Of course this patient represents a rather infrequent type of gall-bladder disease, namely, one that has given no previous sign, in the shape of gall-stone colic, of its existence. The anamnesis in these patients is always of the utmost importance, and in any case in which doubt exists, it should be carefully elicited. It will serve not only to diagnosticate correctly the organ that is diseased, but will also materially aid us in locating the exact site of the calculi,—whether they are in the cystic, or hepatic, or common bile ducts. Another point of interest in connection with the case is the fact that the operation, though extensive and rather prolonged on account of the adhesions, could be very satisfactorily performed under local anæsthesia. The indications prompting me to the selection of eucaine, rather than a general anæsthesia, were the wretched general condition of the patient, and the existence at the time of her admission of a marked hypostatic pneumonia. It might be said that, with patients of good courage and physical endurance, most of the surgical procedures could be carried out under local anæsthesia, without the infliction of very much pain. The great advantages of general anæsthesia lie in the complete relaxation induced by their administration, and in the unconsciousness of the patients to the fact that they are being operated upon.

Case IV.—A case of acute perforative appendicitis, with localized abscess, complicated with a large ovarian cyst and pyosalpinx; incision of the abscess and drainage; healing of the abscess formation; secondary operation for the removal of the appendix, ovarian cyst, and pyosalpinx; recovery.

Elizabeth G——, thirty-five years old, a very obese woman, a widow, was admitted to the surgical service, June 30, 1900. Her illness was of four days' duration, having commenced with general abdominal pain, which later became localized in the right iliac fossa. There were associated with the pain vomiting and fever.

Physical examination revealed a very obese woman, with slight conjunctival icterus. The heart, lungs, liver, and spleen were normal. The abdomen was very much distended, the right rectus muscle rigid and tense, and a very distinct tender mass was to be felt in the right iliac fossa. Vaginal and rectal examinations merely confirmed the presence of this mass. The diagnosis of perforated appendicitis with abscess being made, the writer immediately opened the abdomen under chloroform anæsthesia by the Sonnenberg incision. The peritoneum was found to be œdematous, and the caput coli adherent to the parietal peritoneum. After due protection of the free peritoneal cavity by gauze compresses, the caput coli was separated from its adhesions and an abscess cavity opened into which contained about three ounces of fetid, fecal pus. This cavity was thoroughly cleansed and search then instituted for the appendix. As this could not be readily located, further search was deemed inadvisable on account of the danger of breaking down the adhesions separating the abscess from the free peritoneal cavity. The abscess was therefore drained by tube and gauze, and an aseptic dressing applied.

The patient reacted well from the operative procedure. The abscess cavity healed by granulation. There was a fecal odor to the discharge for several weeks. The patient was discharged July 29th, with the recommendation to return for the removal of the appendix. For two weeks after leaving the hospital the patient remained well. Then she commenced to suffer with pain in the bladder, especially on urination. She was told by her physician that she had cystitis, and her bladder was irrigated. The pain persisted, and radiated to the left iliac region. There was no vomiting, no chill or fever; her menstrual history was negative.

Abdominal examination showed the scar of the previous operation in good condition. Over this there was slight pain. The abdominal wall was soft, but nothing could be palpated within the abdominal cavity. In the right vaginal fornix was a tender mass which stretched for a short distance to the left pelvic region. The rectal examination was negative.

In view of the fact that I knew the diseased appendix was still within the abdomen, I concluded that this organ was the chief source of the trouble, although the tender mass in the right vaginal fornix distinctly suggested an associated pyosalpinx. On the 23d of August, under chloroform anæsthesia, I again opened the abdomen to the left of the former incision. When the peritoneal cavity was opened a dense mass of adherent omentum presented. This was divided between two sets of mass ligatures. The deeper parts being now exposed, the large ovarian cyst with very flaccid walls was seen. The pedicle of the cyst was wrapped up in dense adhesions, with a pus tube the size of an orange. After due protection of the peritoneal cavity, the cyst and tube were separated from their adhesions, their pedicle was secured with silk ligatures, and the diseased structures were ablated. Search was now made for the appendix. It was readily found embedded in adhesions. Its mesentery was secured, and the organ removed. Its mucosa had become obliterated for two-thirds of its extent. The abdomen was partly closed, a gauze drain being passed to the stump of the broad ligament; aseptic dressing.

Subsequent history: The patient reacted well from the operation; the bowels moved on the second day; the gauze drainage was removed on the fourth. The wound healed per primam; the drainage opening closed by granulations in six weeks, when the patient was discharged cured.

Remarks: This case again shows the difficulty of accurately diagnosticating the exact pathological condition. Those who are accustomed to examine the genital organs of the female know that in obese patients it is a matter of extreme difficulty to map out a flabby, cystic ovarian tumor. The reason is self-evident. The flaccid, non-resisting mass offers to the examining hand the same sensation as does the loose fat. This fact should always be borne in mind before establishing the diagnosis of appendicitis in the female; for should such a cyst become twisted upon its pedicle it would give rise to symptoms strongly simulating an acute appendicitis.

Upon this patient's first admission to the hospital the presence of even a rather large ovarian cyst was not made out, although a careful vaginal and abdominal examination was made. As regards the pyosalpinx, the mass produced by the pus tube was detected and recognized at the first examination, but as the left vaginal fornix was comparatively free, and as the mass in the right fornix appeared to be continuous with the inflammatory focus in the right iliac fossa, it was considered that both were due to the same cause, namely, the appendicular abscess. At the time of the first operation, I contented myself with evacuating the abscess cavity around the appendix, and did not wish to expose the patient to the increased risk of

breaking down adhesions for exploring purposes. On her readmission to the hospital the pyosalpinx was at once detected, although its importance as a factor in producing the return of the symptoms could not be fairly estimated, as a diseased appendix was still within the abdomen. As regards the advisability of removing the appendix at the time of the first operation, it is the custom of the writer never to jeopardize the chances for recovery by breaking down adhesions in a search for an appendix that probably in itself forms one of the walls of the abscess cavity. When, however, the appendix can be readily located, in these cases its peritoneal covering is split, and its mucosa shelled out. The acting cause of a subsequent attack of inflammation of the appendix can be thus removed, and yet the patient not be exposed to any added risk by breaking down the peritoneal adhesions that it has formed.

Case V.—Lymphosarcoma of the intestine and retroperitoneal glands; exploratory laparotomy; recovery from the operation.

Max G——, thirty-five years old, admitted June 28, 1900. He had been in his usual good health until five days before, when he was seized with severe abdominal pain and vomiting, and slight fever. The pain became localized in the right iliac fossa; the bowels moved daily. On admission he had a temperature of 100.4°; pulse, 98; respiration, 28. Physical examination showed the man to be in poor general condition, though rather well nourished; the heart and lungs were normal. The abdomen was much distended and very rigid, and tender to palpation. There was no indication of free fluid within the peritoneal cavity. The liver and spleen appeared to be of normal size. In the right iliac fossa was a tender mass the size of a large orange. This mass could be palpated per rectum. Some slight enlargement of the axillary and cervical lymph glands existed. The diagnosis of appendicitis with abscess having been made, immediate operation was proceeded with. The abdomen was opened in the right iliac region with a Kammerer incision. After incision of the parietal peritoneum the intestines were found to be matted together with fresh adhesions. Between the adherent coils were collections of sero-sanguinolent fluid. Exploration revealed a large number of nodules, varying in size from a hazelnut to a walnut, situated in the mesentery of the small intestine. The omentum likewise was rolled up into a thickened, indurated mass, adherent to the intestinal coils. A part of the omental tumor was excised for pathological examination. The small intestine itself, at its mesenteric attachment, likewise contained several of these nodules. The adhesions were general throughout the abdominal cavity and the appendix could not be readily located. The diagnosis of lymphosarcoma of the omentum, intestines, and glands was made. The abdomen was closed by through-and-through suture, slight drainage being provided.

Subsequent history: The patient reacted well from the anæsthetic; the drainage was removed on the second day; the wound healed primarily. There was a daily increase of temperature to about 100°; otherwise convalescence from the operation was uneventful. The pathologist, Dr. Mandelbaum, reported the excised specimen of omentum to show lymphosarcoma.

The patient was given hypodermic injections of arseniate of sodium, but no material change was noticed from its use.

July 15th, the wound was entirely healed. The tumor mass was palpable in the right iliac fossa; apparently it had increased in size. The general condition of the patient had not improved, and he was discharged at his request. Subsequent attempts to locate him have been unsuccessful.

Comments: I have presented this history because it illustrates one of the rare mistakes in diagnosis. Lymphosarcomatous degeneration of the mesenteric glands is not a very frequent disease. Very often, as in the above case, it simulates appendicitis. I know of no way in which the differential diagnosis can be made, except when there is a previous history of abdominal tumor, or when there are several tumors to be felt in the abdomen.

I think the cases I have cited sufficiently illustrate the difficulties that are and may be encountered in establishing a diagnosis in disease of the right side of the abdomen. Pain over the classical McBurney's point is not by any means always appendicular in origin: and again I would suggest that, before appendicitis is diagnosed, the other organs in the abdominal cavity be investigated.

TONOMETRIC EXAMINATION IN CHRONIC DISEASES OF THE HEART.

By PROF. THEODOR SCHOTT, M.D.,

BAD NAUHEIM, GERMANY.

The treatment of chronic diseases of the heart by means of baths and gymnastic exercises, as introduced into medical practice by my late brother and myself, is so well known to the readers of this journal and probably to the profession generally throughout the United States, that a detailed description of the same is uncalled for here. The principles which we established have been fully confirmed by the repeated studies and experiences of our colleagues and followers, as regards the indications for treatment as well as the improvements and recoveries which may result.

That improvement which we especially observed, namely, the changes in the form and size of the cardiac wall, and which gave rise to much discussion, has been most satisfactorily confirmed by means of the Roentgen rays; the results obtained by the use of the latter proved to be almost identical with those established by percussion. The details of the *x*-ray examination have been fully stated by me in this journal, March 26, 1898, whereby my previous experiences and deductions were most fully corroborated. I was thereby enabled to prove that by the application of thermal mineral baths containing carbonic acid, combined with the administration of systematic therapeutic exercises with resistance and self-resistance, an increase of the contracting vigor of the heart could be demonstrated, resulting in a slower but more powerful pulsation, which caused a dilatation to decrease or entirely to disappear.

The diagrams of the pulse taken in the course of such a treatment gave striking proofs of what had been asserted, by an increase of the primary elevation, by a greater distinctness or augmentation of the elastic elevations, a rising of the elevation produced by the shutting of the aortic valve, etc. Although these examinations seemed clear and unobjectionable, yet many eminent medical authorities refused to be convinced concerning the blood pressure.

My brother and I were long ago able to demonstrate and prove by experiment that by the administration of properly regulated thermal baths containing carbonic acid gas, combined with a methodical use of gymnastic exercises, an increase of the blood pressure could be more certainly produced. Fully twenty-five years ago, my brother, in experiments which he made with shorn rabbits in the physiological laboratory of Professor Heidenhain at Breslau, found, after the application of thermal baths, of indifferent temperatures, containing chloride of sodium and more or less of chloride of calcium in solution, an increase of the blood pressure, measured in the carotid artery, of

from five to ten or more millimetres of mercury. I have myself, in a series of published cases, given detailed statements regarding the increase of blood pressure caused by the administration of natural or artificial Nauheim baths and by the use of therapeutic exercises, all of which have been confirmed by means of the sphygmomanometer of Basch. Many of my colleagues and followers have been able further to confirm these observations of mine by the use of other instruments, such as those invented by Potain, Oliver, etc.

Notwithstanding all these observations and testimonials, there are those who have doubted and even still doubt the correctness of my assertions, and who claim that they have noticed a decrease of the blood pressure, where by the use of our remedial measures there should have been an increase of it.

This discrepancy will be accounted for by a few explanations, which, for lack of space, I must give very briefly. The differences in the results observed were mainly due to the instruments hitherto applied to the body. However valuable they were in their kind, still they were unfitted to settle decisively the point in question, for the following reasons:

1. The height or degree of pressure as measured by the touch of the finger varies not only if different observers examine the artery at the same spot, but a difference more or less significant will often be observed under the touch of the same examiner.

2. In an advanced sclerotic condition of the vessels the height of the blood pressure is sometimes delusively great in consequence of the resistant and rigid condition of the arteries, and when from other symptoms we know there exists a low blood pressure; and

3. A swollen condition of the tissues over the artery may in some cases seriously influence the examination of the blood pressure.

All these facts will sufficiently explain why the results of examinations made by different persons vary, and we must conclude that the records of the instrument were too much subject to the action of the individual observer. In a word, the apparatus hitherto in use has not been sufficiently accurate for unequivocal demonstration. We have, therefore, great reason to be gratified and pleased with the invention by Gaertner of his tonometer, an instrument with the help of which we know and behold with our own eyes the moment in which the blood gushes into the tip of the examining finger, or, differently expressed, we are enabled to read directly from the instrument the highest pressure of the blood at the time of examination.

As this apparatus is well known to most of your readers, a description of it here is unnecessary, but I may mention that in all examinations of a minute character I never use any but the mercury apparatus, as the pocket instrument of the same kind often shows differences and is, therefore, unreliable. Moreover, the instrument which I prefer permits of a more distinct and accurate reading of the resulting figure. It is true that constant use of and long-continued experience with Gaertner's tonometer are indispensable. In the first place, we must not regard the first tonometric figure as the correct and reliable one. It is well known that the momentary state of the nerves greatly influences the blood pressure, that is, the tonometric figure, and that in patients who are not of a nervous disposition the first recorded height is generally too great. Therefore, care should be taken that as far as possible during the examination the patients should be free from excitement, and that they should not even look forward to the measurement with too keen an interest. For this purpose, the attention of the patient should be distracted as much as possible from the manipulation, and we must not consider our task completed until the measurement shows an almost equal result on several fingers of the same hand, or by turns on both hands.

Further, we must not regard the pale-red color of the finger-tip which at first appears as the definite condition for measurement; on the contrary, a real purple color must be distinctly observable. I have had frequent occasion to convince myself that on this point my colleagues have erred, and have thereby been led to record too high a degree of blood pressure. Oft-repeated experiments and observations of different kinds will, however, easily disclose the sources of such mistakes.

It is certainly conceivable that repeated examinations of the blood pressure, taken upon the same person and made with the careful avoidance of the above-mentioned errors, would give identical results, and that these results would be of great value, because the blood pressure ascertained by means of the tonometer represents, for physiological reasons, almost exactly the real blood pressure in the small arteries. Now, if we know the degree of blood pressure in the small arteries, it is an easy matter to calculate the degree of pressure in the large arteries and in the heart itself. It was, therefore, with much surprise that last spring I casually read statements which were contradictory to the results obtained by means of the tonometer by myself and colleagues.

In this connection I have to add only that, with a purpose of obtaining perfectly reliable facts, every possible care was taken in making my experiments to avoid those possible sources of error to which I have already directed attention. It is quite conceivable that a neglect to guard against these sources of error may account for the contradictory conclusions arrived at by other experimenters.

While recording in this article the results of my experiments relative to the blood pressure in the course of a balneological and gymnastic treatment of chronic diseases of the heart, I must direct the attention of the reader to some other points which it is of special importance to attend to during the application of the tonometer.

As the inventor, Professor Gaertner, justly observes, it is necessary to place the instrument in such a way that the finger selected for the examination is kept during the manipulation on a level with the heart. That striking and great differences arise from a want of attention to this point, I have proved experimentally by ascertaining the tonometric figure of one and the same patient, with the hand raised first to the height of the mammilla, after that to the level of the shoulder, and finally above the head. The results were as follows:

	Mammilla.	Shoulder.	Head.
Patient Fl	115	90	75 mm. Hg.
" Dr. M.	120	110	80 "
" K.	130	105	90 "

It is, therefore, perfectly evident that examinations of blood pressure taken at one time with the manipulated finger on a level with the heart, and at another time when the same patient is in the bath tub, with the finger, of course, higher than the heart, and even as high as the shoulder, will give different tonometric figures; and that, without further precautions, it is absolutely impossible to determine the effect of a bath upon the blood pressure. Hence, with a view to obtain a uniform and reliable basis for the manipulation, I caused a small table to be constructed, which, by means of a screw, could be raised or lowered in the bath-tub. The tonometer and the hand of the patient rested upon the table board. In every case in which the blood pressure was measured while the patient was

on the sofa, I have taken special care that he assumed the same position as in the bath-tub, and that both the finger and the tonometer were on a level with the mammilla.

Care must also be taken lest the fingers under examination get too cold, for thereby the vessels are contracted and the figures obtained will be much too low. In conducting the examination it is a matter of indifference which finger is selected, provided that the rubber ring, which is applied before being blown up with air, must be neither too tight nor too loose, and that it be not placed directly over a joint. With careful attention to the above-mentioned precautionary measures, one is sure to obtain reliable results for a satisfactory comparison.

During the last two years I have made, partly alone and partly with the aid of my assistant, several thousand tonometric examinations—many of them in the presence of colleagues of mine—with the result that I am fully convinced that cases of the same disease and in the same stages thereof will show corresponding figures both in the course of the bathing and of the gymnastic treatment. I quote here a few cases among many.

P. R——, male, aged twenty-three years, suffering from mitral insufficiency and dilatation of both ventricles. His condition has been aggravated through bicycling. He complains of palpitations and of dyspnœa. I ordered fifteen minutes' rest before taking Nauheim effervescent bath of Spring No. VII. of a temperature of 89.6° F. and ten minutes' duration.

	Frequency of the Pulse.	Respiration.	Blood Pressure, Tonometric Figure.
Before bathing	92	22	102
After 2 minutes' bathing.	81	Not counted.	115
" 6 " "	78	18	117
" 8 " "	78	16	129
" 10 " "	82	18	125
After 6 minutes' resting .	80	16	125

The following diagram, taken before, during and after the bath, shows distinctly its effect.

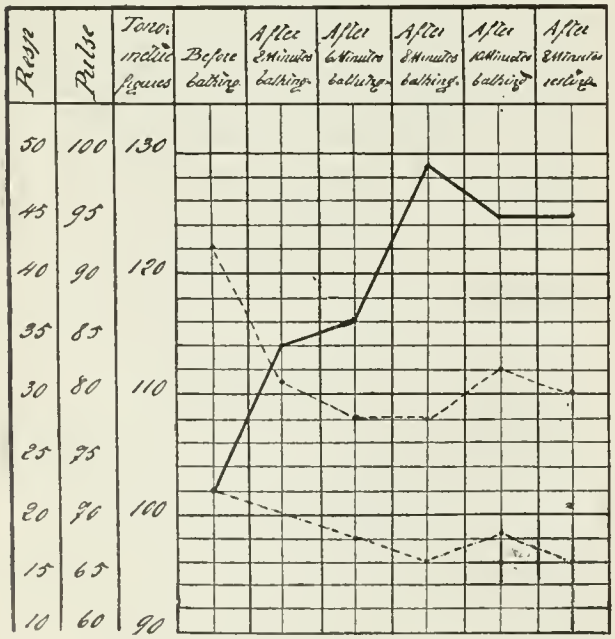

FIG. 1.—Tonometric Figure, ——; Pulse .....; Respiration, —·—·—.

A. W——, male, aged fifty years, with cor adiposum, debilitas cordis, dilatation ventriculorum amborum præcipue ventriculi sinistri. I ordered before bathing forty-five minutes' rest. He takes an effervescent bath of Spring No. VII., temperature 88.7° F., ten minutes' duration.

	Frequency of the Pulse.	Respiration.	Fressure of the Blood, Tonometric Figure.
Before bathing	76	24	101
After 2 minutes' bathing.	74	19	110
" 5 " "	70	18	110
" 7 " "	68	16	114
" 10 " "	68	16–17	116
After 8 minutes' resting...	66	17	122

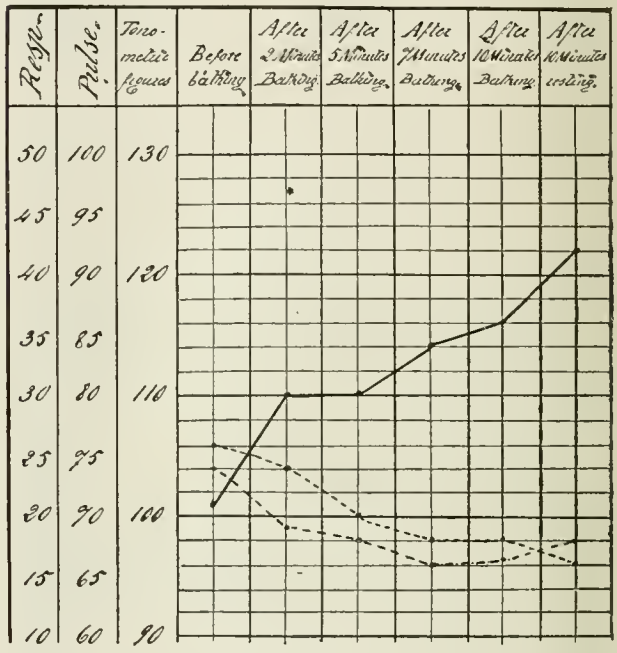

FIG. 2.—Tonometric Figure, ——; Pulse Frequency, ...; Respiration, —·—·—·.

By means of this diagram we see in this case the same uniformity of results, and we also find that the tonometric measurements reflect like a mirror the workings of the pulse and respiration.

We find that just in proportion as the pulse and respiration rates are lowered to a more natural frequency, the blood pressure rises to a more normal height.

Some of my cases were of great interest to me in another direction, and emphasized the necessity for another precaution, namely, if through an insufficient closing of the stop-cock, as will now and then happen even in Nauheim, a more or less violent escape of carbonic-acid gas occurs, evoking a shortness of breath in the patient, the blood pressure is at once lowered, indicating failure of heart power, while, per contra, the pulse and respiration rise, also indicative of cardiac failure. This is illustrated in the following case:

M. R——, male, aged fifty-three years, with debilitas cordis, neurosis cordis motor.

	Frequency of Pulse.	Frequency of Respiration.	Blood Pressure.
Before bathing	90	21	147 mm. Hg.
After 2 minutes' bathing ..	96	24	135 "
" 3 " " ..	98	24	132 "

Great care, therefore, must be taken in the administration of carbonic effervescent baths, lest the air of the bath-room become surcharged with the gas. It would take me too long to state here the differences of the blood pressure in cold and hot baths. Perhaps I shall find another occasion to recur to this subject. The result of experience up to this time in the systematical use of exercises with resistance and self-resistance in cases suitable for the administration of such treatment, would lead us to expect that in these

cases also the tonometer would have shown an increase of the blood pressure. And, in fact, the experiments made by me during the past year fully confirm all those which I had occasion to make in preceding years.

For want of space, I relate here a few cases without adding diagrams:

Dr. J——, physician, aged forty-seven years, with insufficientia et stenosis mitralis, œdema pedum, intumescentia hepatis, dyspnœa. Before the therapeutic exercises a rest of one hour is ordered.

	Frequency of Pulse.	Respiration.	Tonometric Figure.
Before the exercises	90	26	103 mm. Hg.
After 5 minutes' exercises with resistance	75	24	117 "
After 10 minutes' exercises with resistance	70	25	124 "
After 15 minutes' exercises with resistance	65	24	123 "
After 20 minutes' exercises with resistance	62	24	130 "
After 20 minutes' resting	62	24	133 mm. Hg.

G——, male, aged fifty-six years, with stenosis aortæ, hypertrophia et dilatatio cordis.

	Frequency of Pulse.	Respiration.	Tonometric Figure.
Before the exercises	65	24	157 mm. Hg.
After 5 minutes' exercises with self-resistance	62	22	180 "
After 10 minutes' exercises with self-resistance	66	24	175 "
After 15 minutes' exercises with self-resistance	61	21	182 "
After 10 minutes' resting	60	18	185 mm. Hg.

Of course, in those cases in which the therapeutic exercises have been abused, or for any other cause the patient has over-exerted himself, the record of the blood pressure will be of a different character. I shall treat of this on some other occasion. Those cases in which the Cheyne-Stokes phenomenon occurs are most instructive, as an accumulation of carbonic acid in the blood is then known to exist and to cause an abnormal height of blood pressure. In such cases we find, although not always, according to the stage and progress of the disease, that by means of the gymnastics and also by the use of the mineral baths, the blood pressure is either temporarily or permanently reduced. A similar effect may be expected in cases of anæmia.

Aided by my assistant, I have taken notes in several hundred consecutive cases undergoing the combined balneological and gymnastic treatment, and the results thus obtained have fully confirmed all that I have claimed. I mention herewith only three cases:

	Blood Pressure.		
	Before Treatment.	After Treatment.	
Dr. St., physician, aged forty-one years; debilitas cordis, dilatation of both ventricles, neurosis cordis sensibilis et motor	100 mm. Hg.	52 days.	125 mm. Hg.
Dr. J., physician, aged forty-seven; insufficientia et stenosis mitralis, intumescentia hepatis, etc	95 "	72 "	130 "
Dr. C., physician, aged forty-nine years; myocarditis ex cor adiposum, dilatation of both ventricles	85 "	30 "	115 "

The diagrams of the pulse taken simultaneously with the tonometric examinations, during the balneological and gymnastic treatment, show the changes which my readers are already acquainted with; therefore, I do not reproduce them here, nor do I consider it necessary to give the cases in detail.

With regard to massage, I can only repeat what I have hitherto stated on that subject, namely: That whenever used it has had little or no effect upon the blood pressure.

It was with considerable curiosity that I made some tonometric examinations in cases of heart disease in which I knew that the balneological and gymnastic treatment was contraindicated, namely, cases of far advanced arteriosclerosis, of far advanced myocarditis, and of aneurism of the heart and the aorta. Here, also, my former experience was fully confirmed. I cite the two following cases:

T. S——, male, aged forty-seven years, with myocarditis, dilatatio ventriculorum amborum, congestio hepatis, ascites, œdema pedum, dyspnœa.

	Frequency of Pulse.	Respiration.	Tonometric Figure.
Before bathing	108–110	27–28	230 mm. Hg.
After 4 minutes' bathing (Spring No. VII., temp. 90.5° F.)	118	28	115 "
After 8 minutes' bathing (Spring No. VII., temp. 90.5° F.)	130	30	85 "
After 5 minutes' resting	125	29	125 mm. Hg.

H. Z——, male, aged forty-five and a half years, with aneurysma aortæ, arteriosclerosis.

	Frequency of Pulse.	Respiration.	Tonometric Figure.
Before bathing	75	22	105 mm. Hg.
After 2 minutes' bathing (Springs VII. and XII., temp. 90.5° F.)	82	26	82 "
After 5 minutes' bathing (Springs VII. and XII., temp. 90.5° F.)	81	25	90 "
After 8 minutes' bathing (Springs VII. and XII., temp. 90.5° F.)	86	24	88 "

Then, shortness of breath with cough supervening, the patient had to leave the bath.

With few exceptions, it may be considered a serious symptom whenever, in cases undergoing the balneological or the gymnastic treatment, the blood pressure is lowered; and I have no hesitation in saying that when a tonometric figure as low as 65 or 60 mm. of mercury is found, therapy is of little avail, and the bath and exercise treatment are wholly contraindicated. Very recently a case of advanced myocarditis, originally due to gout and malaria, came under my notice. It had not previously been under treatment. To the myocarditis were added violent attacks of diarrhœa, and in this case a lowering of the blood pressure to the extreme figure of 45 mm. of mercury was noted about eight hours before the fatal end, although at the time the patient declared that he felt better.

Future experience must determine what is the exact degree of low blood pressure which must be regarded as dangerous and as indicating an exitus lethalis.

Although the old rule that practitioners should manage with as few instruments as possible is certainly correct, yet of late years the instruments for physical examination have rapidly increased in number. Therefore, when a new apparatus for physical diagnosis is brought forward, it behooves us to ask ourselves whether we really stand in need of it. The general practitioner may dispense with the tonometer, but the physician who is desirous of making minute and careful observations, or who is in quest of an excellent expedient for demonstrating the blood pressure,

will find in the tonometer an instrument especially adapted to his purpose, provided that with its use he combines the necessary care and diligence to avoid the sources of error to which I have called attention. I have not the slightest doubt that further careful experience with Gaertner's tonometer will fully confirm the statements and facts which I have given in this treatise.

CHRONIC GONORRHŒA AND POST-GONORRHŒAL URETHRITIS—A SKETCH OF THEIR MODERN TREATMENT.[1]

By FERD. C. VALENTINE, M.D.,

PROFESSOR OF GENITO-URINARY DISEASES, NEW YORK SCHOOL OF CLINICAL MEDICINE; GENITO-URINARY SURGEON, WEST SIDE GERMAN DISPENSARY; GENITO-URINARY CONSULTANT, UNITED HEBREW CHARITIES AND METROPOLITAN HOSPITAL AND DISPENSARY, ETC.

A GONORRHŒA may become chronic from, and a post-gonorrhœal urethritis may be perpetuated by, (1) lack of treatment, (2) misdirected treatment, (3) insufficient treatment, (4) over-treatment, (5) infraction of dietetic or hygienic regulations, (6) constitutional disturbances, (7) congenital or acquired deformities and complications, (8) involvement of the urethral adnexa, (9) marital reinfection.

In addition to the above, some gonorrhœas, as Guiard[2] has shown, present all appearances of being chronic from their very inception (*blenorrhagie chronique d'emblée*).

In studying the modern treatment of chronic gonorrhœa and of post-gonorrhœal urethritis, it is useful to consider the above causes of chronicity. Such a study must necessarily be in coarse outlines, lest the perfectly proper time-limit set upon papers before this Congress be exceeded.

1. Lack of treatment. Despite the efforts of those who have labored and are laboring most assiduously for the true understanding of gonorrhœa, there are still colleagues who dismiss it as a trifling ailment. This view is transplanted to the public, most of whom cannot understand the need of treatment when they suffer little or no pain, and are barely disturbed by slight inconvenience. Thus unchecked, the gonococci proliferate; they invade the depths of the urethral tissues, make many a nidus in its crypts, glands, and follicles; penetrate the adnexa, so establishing a chronicity which is often very tardy of cure. The patient must ever be reminded that until a cure is effected he carries with him danger of infection to himself and others.

2. Misdirected treatment is perhaps more frequently the cause of the persistence of gonorrhœa than are all the others combined. This misdirection at the present time is happily less frequent than it was formerly. But, unfortunately, gonorrhœa is still, in the eyes of the laity, the proper field in which the quacks and nostrum venders may exploit the public. And as long as the public, through its lawgivers, refuses to pass and enforce enactments for its own protection, so long will charlatanism flourish.

Another flagrant means of misdirecting treatment lies in the too prevalent custom of relegating the details of the treatment of gonorrhœa to the patient himself. This is often done, apparently under the assumption that a layman is necessarily born with the knowledge and skill which the physician attains only after many years' study and experience. The patient cannot know, unless instructed, how dangerous a disease gonorrhœa is, nor can he intelligently and dexterously treat so delicate a canal as the urethra until he has been properly instructed therein.

3. Insufficient treatment is often the reason for a gonorrhœa becoming chronic. When effective care causes pain quickly to disappear and the discharge to be reduced to a mere mucoid excess of urethral moisture, the patient, unless thoroughly warned, is likely to leave the rest to nature. How this fair lady treats him is recorded in the history-books of physicians in general, and of genito-urinary specialists particularly.

4. Over-treatment, too, can maintain a urethral discharge indefinitely. The gonorrhœa may long ago have subsided, but an irritative urethritis can be maintained without any specific lesion in the canal to account for it. In these cases, when treatment is stopped, the patient gets well.

5. Infractions of dietetic and hygienic regulations often insure the chronicity of a clap. There are, however, but relatively few patients, and these among the most depraved, who will not abstain from those indulgences which their physicians tell them are noxious. Indeed, these cases are most exceptional when the patients are properly impressed with the fact that, while they have gonorrhœa, they are a danger to themselves and to others.

6. Constitutional disturbances, such as depressed conditions from malnutrition, anæmia, lowered vitality from overwork, unhygienic living, dissipation, etc., naturally place the vitality at a disadvantage in the struggle against microbic invasion. Manifestly in such cases local treatment alone rarely suffices to prevent gonorrhœa from becoming chronic.

7. Congenital or acquired deformities and complications in the genito-urinary apparatus naturally offer mechanical impediments to effective local treatment. It behooves us to study the most frequent of these, as much in detail as is permissible in so brief a paper as this.

It will be convenient to consider the most frequent deformities and complications of gonorrhœa according to their anatomical site. In doing so we first meet with

Deformities of the prepuce. Congenitally this fold may be very large, with or without tightness preventing its retraction. Acute inflammation may also thicken it immensely with the coverings of the penis, as in a lymphadenitis or lymphangitis. Its orifice may be very narrow from birth, or in consequence of cicatricial contractions. Any of these conditions may lay the foundation for a severe phimosis or paraphimosis. Not at all infrequently in young subjects with a first gonorrhœa the prepuce is found adherent to the glans, rarely in its entirety, more often in spots. All of these states unrelieved make violent balanitis and balano-posthitis unavoidable, and provoke condylomata in consequence of the local irritation, compression, and maceration of the mucosa.

When the preputial infiltration is acute, and even when it has existed for some time, it generally yields to hot antiseptic applications continuously applied. Naturally, when the prepuce is congenitally tight such treatment cannot, even when most successful, do more than reduce the prepuce to its original thickness and dimensions. If this has been attained or not, and if it is not possible painlessly to retract the prepuce, operative intervention is immediately necessary. The dorsal slit, usually recommended, is unsatisfactory even when the prepuce is small and thin, as thereby a rolling pendant is formed of the foreskin, exposing only a small triangle of the glans. This small triangle may expose no serious lesion, while the uncovered and so uncoverable part of the preputial sac may contain chancre, chancroids, condylomata, and may retain immense quantities of pus and masses of decomposing or indurated smegma. To expose thoroughly all parts of the glans in such a phimosis, it is best to make free incision through each side of the prepuce exactly mid-

[1] Presented before the Third Pan-American Medical Congress, Havana, February 4 to 7, 1901.

[2] Guiard: "Les uréthrites chroniques chez l'homme," 1898. Rueff, Paris.

way between the dorsal line and the frenum.[1] These incisions must be carried well down to the coronary sulcus. Rare, indeed, is even an indurated prepuce which does not, after the escape of some blood, become so manageable that the entire glans and the inner preputial surface can be readily examined and any lesions found there treated. Later on, when active local conditions have subsided, circumcision may be completed for cosmetic effect.

A very large, heavy prepuce, although it may be easily retractible, may cause a chronic urethritis to continue a very long time. By covering the meatus it prevents free drainage of the canal with consequent retention of its abnormal secretions and thus favors the proliferation of noxious microbes. Manifestly the remedy therefor is circumcision. The method of circumcision experience has led me to prefer, because it is painless and does not disable the patient from his occupation and diversions, is elsewhere fully described.[2]

A stenosed meatus, congenital or acquired, may be the essential element for the indefinite prolongation of a gonorrhœa. In a fair number of cases the stenosis yields to gradual dilatation, but in the majority meatotomy is required.

Stenosis of the posterior boundary of the fossa navicularis not infrequently accompanies a small meatus, although each may exist independently of the other. This stricture is amenable to the same treatment as is that of the meatus. It is well to keep in mind, when performing a meatotomy, that the posterior fossal boundary may be tight. The same incision which relieves the one should then also embrace the other.

Para-meatal fistulæ, sometimes exceedingly minute, may open near the external urethral orifice. They must be sought for and either destroyed by electrolysis, or opened into the meatus by incision, according to their size and their relations to the channel. If this is not done, these fistulæ, harboring gonococci, may continually reinfect the urethra and thus indefinitely maintain its inflammation, despite the best-directed efforts that may be made.

Hypospadias or epispadias of the glans may render the thorough treatment of gonorrhœa difficult, but does not usually cause much prolongation of gonorrhœa. When, however, the infection is reduced to a minimal state which defies treatment, radical operation for the cure of the deformity in hypospadias (preferably by

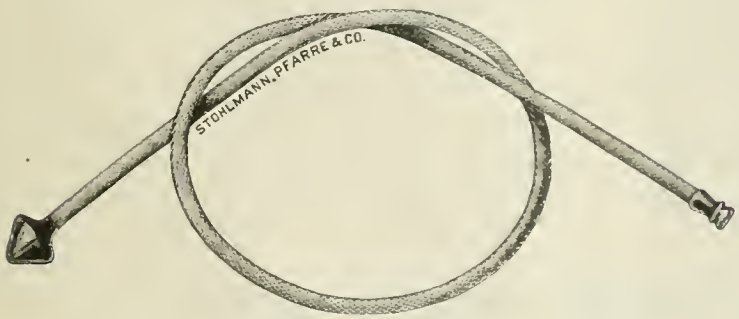

FIG. 1. Bougie-à-boule.

Beck's method[3]) may be required before final recovery is obtainable.

Condylomata on the glans, the prepuce, within the meatus or the urethra, may prolong a gonorrhœa into chronicity. As Posner[4] has shown, when extra-urethral warts are pedunculated, they almost invariably yield to local applications of powdered savin; sometimes sessile condylomata also are removed by the use of this drug. When this fails, they may be painted with tincture of iron and curetted daily or every second day, or they may be excised and their bases cauterized with nitric acid. When they are located within

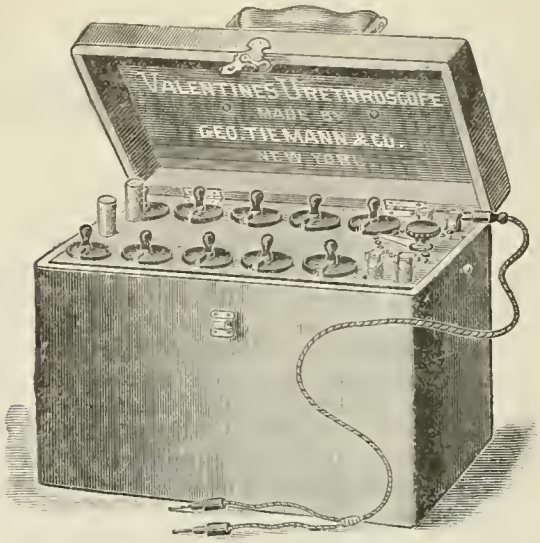

FIG. 2.—Valentine Urethroscope.

the urinary channel, they usually require removal through the urethroscopic tube.

Residua of previous infections of the urethra manifestly must be cured before a new infection can be obliterated. These residua, however long quiescent, can at any time produce what resembles a new gonorrhœa, although the patient may be innocent of a fresh exposure. It would be a sad commentary upon matrimonial fidelity if every man, who even in the remote past had a gonorrhœa, were accused or accused his wife of unchastity, should recrudescence occur of a gonorrhœa so old as to be almost forgotten. This fact emphasizes the need of physicians to instruct the public on this subject, and of warning men not to marry until careful examination has proved that they are free from infectious material. This subject, however, is detailed elsewhere.[1] The most important residua of previous urethral infection which render a gonorrhœa chronic are infiltration of the mucosa, stricture, retention of gonococci in the crypts, glands, and follicles, and neoplasms.

The methods of diagnosing these conditions, beside a close study of their symptoms, are in microscopical examination of the urethral discharge, microscopical examination of the urine, and physical exploration of the urethra.

The last mentioned is accomplished first, by palpation of the external coverings of the channel, in which experienced fingers can often elicit the location of even minute lesions; but with certainty as to the site of an abnormality, the diagnosis is by no means accomplished. In connection herewith it must be remembered that the patient's sensations often are misleading. As merely one example thereof, we may now recall that a sense of discomfort, weight, or even pain in the glans may be indicative of no lesion there, but of a prostatic involvement.

Therefore our senses, feeling, and sight must be called into service, so that our treatment may be guided by correct diagnosis.

All too frequently do we find that physicians, other-

wise very well informed, are satisfied to declare the urethra free from obstruction when a large-sized sound glides easily and smoothly through the canal. But if they would invoke the aid of a well-constructed, very soft bougie-à-boule, the shoulder of whose acorn is almost at a right angle to the shaft of the instrument, they will find that on deftly withdrawing it from the urethra it is more or less withheld by a series of contractures. With experience, and consequent higher development of the sense of touch, one learns to distinguish by means of this invaluable instrument normal coarctations, infiltrations of the mucosa, strictures, neoplasms, and very much of the character of each.

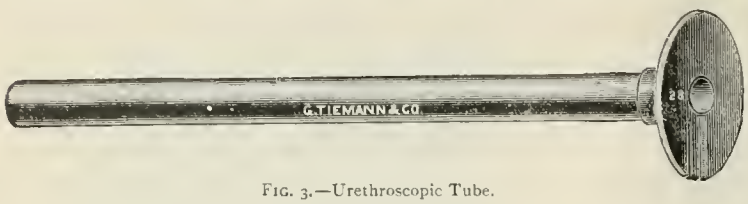

Fig. 3.—Urethroscopic Tube.

Final decision as to precise diagnosis, however, is obtainable only by the urethroscope. The basis of modern urethroscopy was laid by Oberlaender,[1] and to him is due inexpressible credit for giving us the foundation of the treatment of chronic gonorrhœa.[2] The urethroscope he evolved from Nitze's original device, although long the best of its kind, was for many years a deterrent to the use of urethroscopy by practitioners generally. Its fundamental principles were used by me to develop an apparatus which is easily transportable, uncomplicated, and cheap. It is my hope that in demonstrating its use on the patients kindly provided for the purpose, I may be able to make clear that its employment is not at all difficult and entails no discomfort to the urethra. I am convinced that every one who gives himself even less trouble than he must with the ophthalmoscope or other instrument of precision, can learn to diagnose and treat urethral diseases more rapidly than he can those of the eye, the nose, throat, ear, or rectum.

The urethroscope consists essentially of a box weighing about eight pounds and containing all that is necessary for a complete examination of the urethra. It has five short and five long tubes, in sizes from 23 to 32 Charrière. The short tubes bear the uneven numbers and are destined essentially for operative purposes in the prescrotal region, when there is no need of disturbing the urethra behind the penoscrotal juncture. Each tube is provided with its obturator to facilitate its entrance into the urethra. Once in place, the moisture or excess of the lubricant employed is removed by absorbent cotton wrapped preferably about a wooden applicator. The cords attached to the battery are also attached to an appropriate light-carrier, which is inserted into the tube and by slight pressure automatically fastens itself to the disc at the ocular end of the urethroscope. We have now, in obedience to a fundamental optical principle, the best possible illumination by the source of light being almost in juxtaposition with the spot to be illuminated. The minute lamp used for this purpose generates no appreciable heat in the tube and therefore does not interfere with most prolonged detailed examination and local treatment.

Fig. 4.—Obturator.

By means of this instrument the anterior and posterior urethra are brought into as plain sight as if they were on the superficies of the body. With practice the eye learns to distinguish anæmia and hyperæmia of its mucosa, soft, medium, and hard infiltrations, epithelial denudations, strictures, infiltrations of the crypts, glands, and follicles, intra-urethral chancre and chancroid, benign and malignant growths. The treatment of the urethral condition must then be predicated upon the urethroscopic findings. To discuss these and their many variations in more than very coarse outlines would lead far beyond the scope of this modest effort.

Anæmia and hyperæmia of the urethral mucosa are not amenable to local treatment, but must be attacked through the constitutional condition which produces them.

Epithelial denudations generally yield quickly to local applications of silver nitrate in one- or two-percent. solutions.

Infiltrations of the mucosa, the most frequent conditions found, and strictures, are best treated by gradual dilatation. The methodizing of dilatations is due primarily to Oberlaender[1] and the school he founded. Among those who have worked most extensively in the propagation of the principles he advocated are Kollmann, Wossidlo, de Keersmaeker, and numerous others. Of these Kollmann vastly extended the usefulness of the procedure by many, most ingenious instruments, but few of which can be even briefly mentioned here.

Fig. 5.—Light-carrier.

Oberlaender attributes the results of dilatations to "melting of the infiltrates." The great master Guyon holds that the steady pressure—a species of massage I prefer to call it—induces a retrograde metamorphosis of the fibrillary structure into parvicellular, reabsorbable material.

The instruments used for the purpose are briefly:

Soft conical sounds, as long as the urethral calibre is below 21 Charrière or while hyperæsthesia prevents the painless use of dilators.[2] Experience has led me to disagree with those eminent men who use cocaine for urethral analgesia, except when an emergency imperatively demands invasion of the bladder through a hypersensitive canal. Delicacy of manipulation invariably makes cocaine unnecessary; its use not only changes the appearance of the mucosa, but also deprives it of those infinitesimal touches of discomfort which nature has given us as signals to warn against possible local traumatisms. Moreover, it is the experience of all operators that after the use of cocaine or other local anæsthetic, urination is far more persistently painful than if no drug had been employed.

After the urethra has been taught to tolerate instruments, dilators may be used and the dilatations performed exactly in the affected regions. The general practitioner will have occasion to employ Oberlaender's straight dilator for the anterior urethra when the lesion to be treated is within the movable portion of the canal. Oberlaender's antero-posterior dilator, as its

name conveys, is intended to exercise pressure in both urethræ. When the limits of therapeutic power of a two-bladed instrument are attained, Kollmann's four-bladed dilators come into play. All the preceding instruments are used with fine, easily sterilizable rubber

Fig. 6.—Oberlaender Anterior Dilator.

covers. There are now being made, under my directions, new rubber covers for these instruments, which are placed on the market so cheaply that they need not be employed twice, thus saving the operator the trouble and risks of sterilization after use.

Recently Kollmann has devised a new eight-bladed dilator for the anterior urethra, which is employed without a rubber cover. Its blades are so rounded that they cannot injure the mucosa. This instrument is sterilized first by scrubbing with soap and hot water, then immersing it in alcohol and burning the alcohol from its surface.

While firm rules cannot be laid down for the employment of these instruments, the following will apply in the generality of cases:

1. The first dilatation must go no further than that point at which the first resistance to further dilatation is felt by the operator's fingers turning the screw which separates the blades.

2. In the beginning of treatment, dilatations, if done by a novice, must not be repeated oftener than every three or four days.

3. Each session must not extend in time beyond two minutes over that employed at the preceding session.

4. Regardless of any lack of resistance that may present, no dilatation must exceed one-half number Charrière beyond the number attained at the preceding session.

These four rules will keep the practitioner within the limits of safety.

Infiltrations of the urethral crypts, glands, and follicles yield in a great many cases to the treatment above outlined. When, however, they do not, they must be attacked locally through the urethroscopic tube. Oberlaender, Kollmann, and others have devised numerous ingenious instruments for this purpose. Among those most frequently required are Oberlaender's urethroscopic knife for slitting hard infiltrations of the mucosa, infarcted Morgagnian crypts, and Littre's glands; Kollmann's syringe for injecting cauterizants into these crypts and glands, and his electrolytic needle for their complete destruction. I have satisfactorily extended the use of this needle to puncturing extensive, old, very hard infiltrations.

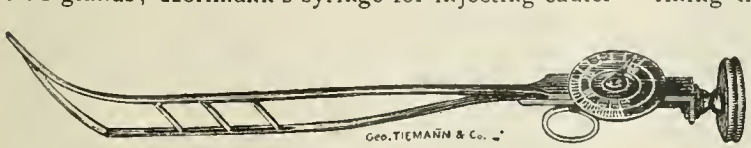

Fig. 7.—Oberlaender Antero-posterior Dilator.

Effective local treatment of intra-urethral chancres and chancroids can be accomplished only through the urethroscopic tube, and intra-urethral growths cannot be otherwise diagnosed or treated. Both Oberlaender and Kollmann have added to our instrumentarium delicate cold and electric snares, forceps, and special cautery-carriers for the removal of these growths and destruction of their bases.

This seems the proper place to remember the need of asepsis, greater if anything, of urethral instruments than of those employed in other parts of the body. The difficulty of sterilizing the surgeon's hands and of rendering hollow instruments aseptic is well known to the profession, and the methods and means employed, while easily accessible in well-equipped specialists' offices, are oftentimes beyond the reach of the general practitioner. Much study and experiment directed to means of obtaining asepsis of the operator's hands and instruments in the simplest possible way have led me to advocate for the past eight months a new preparation called synol soap, whose non-irritating character makes its extensive use not only pleasant, but whose effectiveness has not disappointed me. I use it for the cleansing of my hands and instruments and as a lubricant for urethral instruments. I also employ it as a lubricant for the fingers in rectal and vaginal exploration, and I cause all patients to use it to cleanse their hands after touching their genitals.

While the effectiveness of synol soap (introduced by Goelet,[1] of New York) has passed the stage of doubt, I cannot omit mention of the moral effect upon patients who are instructed to use a special form of detergent. They thus practically are taught the importance of urethral diseases, and the need of scrupulous cleanliness therein, the dangers of contagion, and the urgency of having them radically cured are thus emphasized.

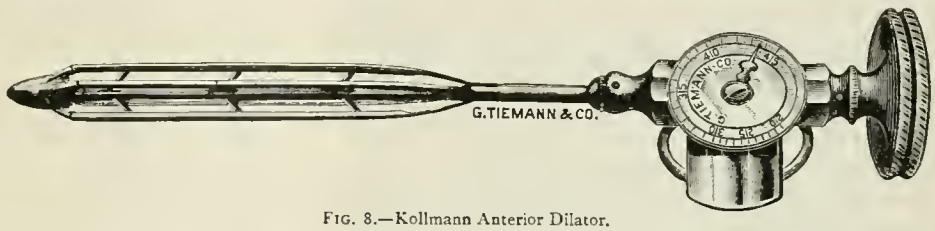

Fig. 8.—Kollmann Anterior Dilator.

As, however, asepsis and the methods of obtaining it are too vast for even cursory consideration here, we must strive to satisfy ourselves by the mere mention of one means which experience has proven satisfactory.

Other conditions than those of deformity or residua of preceding disease of the urethra can insure the chronicity of a gonorrhœa or the continuance of urethritis. Theoretically they may appear due to an infection of the mucosa itself, which perhaps does not deeply invade its stroma and leaves the urethral glands intact, or in which these glands can be made to yield their noxious contents. These are the cases in which irrigations prove so brilliantly effective. Before outlining the method of irrigations, we must pause to give due credit to Janet, who popularized irrigations of the urethra and bladder in the treatment of gonorrhœa. But the somewhat complicated character of the apparatus he devised for urethral and intra-vesical irrigations deterred many from its employment, unless they had by service in the Hôpital Necker become imbued with the scientific enthusiasm with which Janet pursues his work. This caused me to devise an apparatus for the purpose in 1895, and if it is the simplicity of my irrigator, or my writings on the subject which led thousands of physicians in America to pursue the method, my efforts in this regard are amply rewarded.

The device is fully described in my little book, "The Irrigation Treatment of Gonorrhœa, its Local

[1] Goelet: "Aseptic Minor Gynæcology." Journal of the American Medical Association, October 6, 1900.

Complications and Sequelæ," as are the drugs used therewith and their dilutions for the treatment of the acute and chronic urethral and vesical diseases in which they are applicable.

I need but show the apparatus to make evident its simplicity, but cannot now take up the time of the Congress to describe again the technique of its employment. To emphasize the value of irrigations I must, however, repeat here that when irrigations are correctly employed, catheter fever (urethral fever or urinary fever) does not follow urethral or intravesical instrumentation.

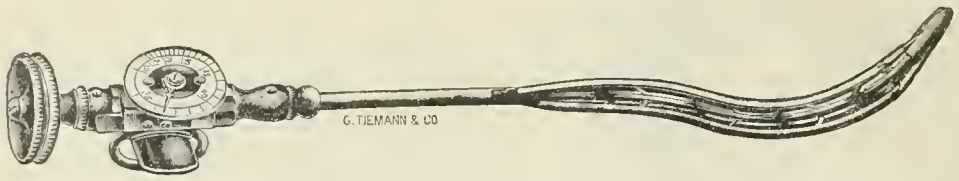

Fig. 9.—Kollmann Antero-posterior Dilator.

The simplicity of construction and ease of manipulation of the urethral and intravesical irrigator which I devised, as well as the success obtained with it by many others, are arguments in favor of its employment. The objections thereto are:

1. It weighs about four pounds, and its dimensions, when packed for transportation, are thirty-six inches in length, eight inches in breadth, and twelve inches at its thickest part. Although this weight and these dimensions are the smallest that can be employed for a convenient and effective irrigator, they preclude its use as a part of the armamentarium which can be carried in the instrument bag.

2. Patients whose occupations prevent their visiting the physician as often as is usually necessary for irrigations would ordinarily by the dimensions, weight, and expense of the irrigator be deprived of its use and consequently relegated to the old form of treatment by syringes.

These two essential objections led to the evolution of what is called the Valentine urethral and vesical auto-irrigator. This apparatus in its entirety weighs eight ounces, and occupies a space of six by two by three inches in the instrument bag; it can be sterilized after each use by merely throwing it into boiling water. It consists of a fine rubber bag, of a capacity of three pints (1,500 c.c.), a tube four and one-half feet in length, a rubber shield and a very soft rubber conical nozzle, whose apex terminates in a thin projection of such delicacy that it cannot injure the most exquisitely sensitive, inflamed meatus urinarius. A wire stopcock easily enables the user to allow mere drops to escape from the nozzle, or by simple pressure to increase the outflow from a gentle stream to a forcible jet, amply sufficient for copious bladder-washings. This auto-irrigator and the technique of its employment require no further description, as its appearance fully shows them. Those, however, who may desire to study the details thereof are referred to a paper entitled "Asepsis of the Urethra and Bladder," read before the American Medical Association in June, 1900.[1]

The preceding considerations have been treated in a superficial manner, utterly out of keeping with their transcendental importance. Though painfully conscious of this fact, the limits that are set, as well as my incapacity to do the matter full justice, oblige rapidly proceeding to the other divisions of the subject of this effort.

8. Involvement of the urethral adnexa. When a gonorrhœa stops its external manifestations, even when the urine has become macroscopically clear, it is by no means sure that the patient is cured. Wossidlo[1] insists that no patient, apparently recovered from gonorrhœa, be dismissed from treatment before the prostate has been examined and found free from involvement. Experience leads me to go further than this eminent author, and to urge that no physician is justified in considering a patient cured, after employing all the ordinarily recommended tests, until examination per rectum has shown that the prostate, seminal vesicles, and Cowper's glands are normal. It is these adnexa which so often carry gonococci without giving external evidence of their presence; if the patient then in ignorance of his ailment resumes sexual relations, he not only may cause a recrudescence of the disease, but may also infect others. The mode of examining such cases and the methods of treating them, if found diseased, are elsewhere discussed.

9. Marital reinfection. It has been often shown, and with what sad results need not be described, that a woman can harbor gonococci without presenting even a slight increase of the normal vaginal secretion. Under favorable circumstances she then may innocently infect a man. I use the adjective advisedly. In illustration thereof let me sketch a not infrequent occurrence. A man thinking himself cured of gonorrhœa marries. The bride, as a consequence of the first conjugal nights, finds herself with what appears to be a slight vaginitis. This soon subsides under the usual treatment, or perhaps under no treatment. Some time later, mayhap several years after marriage, the couple, under a stimulus of any kind, perform the conjugal act once or twice oftener than was their habit. Even without this extraordinary element the husband suddenly finds himself with all the evidences of an apparently fresh gonorrhœa. This may be due:

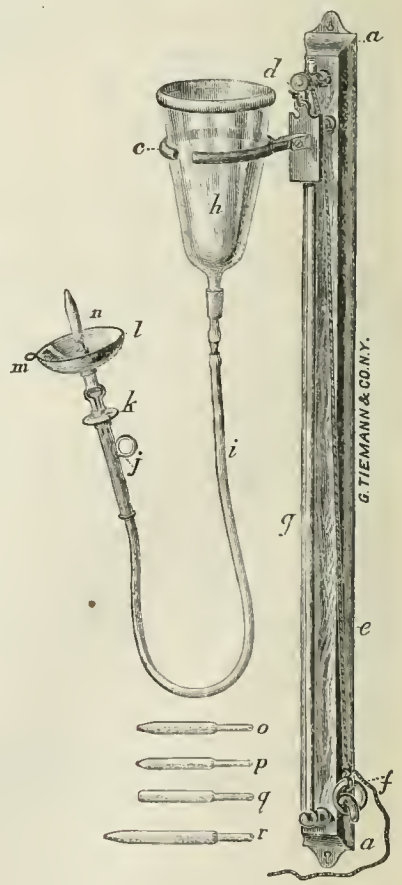

Fig. 10.—Valentine Urethral and Intravesical Irrigator.

1. To auto-infection caused by the discharge of gonococci that have long lain residual in one or more of the urethral adnexa; or,

2. It may be due to infection from the wife having held gonococci residual for perhaps many years, after what appeared during the beginning of her married

[1] Journal of the American Medical Association, January 12, 1901.

[1] Wossidlo: "Chronic Prostatitis and its Treatment." Journal of the American Medical Association, August 27, 1898.

life as only a slight vaginitis. Its manifestations may have been so slight that they were soon forgotten.

A careful search of the husband's genitalia, after the acuity of the apparently new infection has subsided, will reveal the site or sites where gonococci have lain residual, and in accord therewith the condition must then be treated.

Roughly outlined as it is, the matter of marital reinfection has been discussed more extensively than is proportionate with the other divisions of our subject, for the purpose of emphasizing three facts:

1. That the discovery of gonococci in either husband or wife, or in both, is no proof of infidelity in either.

2. That as long as either husband or wife harbors gonococci, the other is not safe from infection while marital relations are maintained.

3. That resumption of marital relations must not be permitted until it is proven beyond peradventure that neither of the couple harbors gonococci.

In submitting this outline of a study of the treatment of chronic gonorrhœa and of post-gonorrhœal urethritis, I beg to offer the following conclusions:

1. That in these conditions, like all others, the cause of the perpetuation of the disease must be sought.

2. That no one remedy exists or can exist which will meet all the causative indications.

3. That the cause of a chronic urethral discharge is easily found, and when found can be successfully treated.

4. That the majority of chronic urethritides can be successfully treated by the general practitioner, and that the services of the specialist are required only in exceptional cases.

5. That the physician's duty is to warn all his patients of the dangers of gonorrhœa to themselves, their family, and the public.

6. That no person who has had gonorrhœa at any time should be allowed to marry until it is proven that he or she is free from the disease.

TUBERCULOUS MASTITIS.

By R. A. GIULIANA, M.D.,

NEWARK, N. J.

A patient came to my office to consult me concerning a cough associated with other pulmonary symptoms. She was twenty-four years of age; Italian by birth. The latter fact makes the case more interesting, as tuberculosis is not so prevalent among Italians as among those of other nationalities, in my experience.

The history of the patient was that her father and one sister had died of pulmonary tuberculosis. On examination, I found that she was suffering from a similar condition, the right lower lobe being consolidated and presenting all the subjective symptoms which exist in pulmonary tuberculosis. I put my patient immediately under the necessary treatment. Three months after I first saw the woman her right mammary gland showed signs of inflammation. As she was nursing a child at the time, I suspected that I had to do with a case of mastitis, due to milk stagnation; but, on making inquiry, I learned that she had had several similar attacks, but in a milder degree. On the strength of this statement and of certain symptoms which did not indicate milk stagnation, I made the diagnosis of tuberculous mastitis.

I saw a similar case some years ago in a woman under nearly the same circumstances. The disease is far more common in women than in men. Warden says that statistics show that 89.6 per cent. of reported cases were in females and 10.4 per cent. in males. Pregnancy and lactation favor its development. Cuneo states that the three possible routes of infection are the lymphatics, the blood-vessels, and the milk ducts. Infection by way of fissures in the nipples is probably more common than that through the milk ducts.

In this case of mine the axillary glands were involved, a condition which occurred before the breast disease had become obvious. In the first case I saw the cervical glands were involved. Cuneo states that the condition is first interstitial, and the giant cells are not situated in the acini. Pain was the first sign which my patient noticed; it was described as being sharp and lancinating in character, radiating to the arm and neck. Finally, a cold abscess formed, which I incised. Pus cocci were plentiful, but the tubercle bacilli were very hard to discover. I curetted the cavity well and injected iodoform emulsion, and packed it with iodoform gauze.

My patient was very weak, otherwise I might have amputated the entire gland, as that is the best procedure, in my opinion, in such cases.

Etiology and Treatment of Pyorrhœa Alveolaris; Stomatitis Ulcerosa Chronica.—F. Forchheimer states that next to caries this is the most common form of disease which attacks the teeth. Primarily it is a gingivitis; secondarily it affects the alveo-dental membrane, and produces an absorption of part of the alveolar process. It is commonly found in connection with diseases of the gastro-intestinal tract, and with either diseases or functional disturbances of the nervous system. Uric acid is rarely absent from the scrapings made from teeth affected by this trouble. Treatment should consist, first, in the removal of all substances that irritate and in antisepsis of the mouth. General treatment should be addressed to the causes mentioned above, or to anæmia, diabetes, syphilis, alcoholism, uric acid, or neurasthenia.—*The St. Paul Medical Journal.*

The Prevention of Tuberculosis.—A. N. Bell says that from a physiological standpoint all observers appreciate the important difference which exists in regard to the requirements of nutrition between the young of all animals and those of mature growth, and in none is it more marked than in the human species. Every organ of the body, in addition to sustenance, appropriates the additional amount of nutriment necessary to give it required bulk. The current of nutritive life in the young is rapid, and the blood itself, from which the organism is built up, receives its impressions and modifications—its constitutional predisposition—chiefly from the nature of the food during the growing period of life. Hereditary tendencies may often be wholly overcome by a change in the quality of the nutriment and the physical surroundings, while the inheritors of healthy constitutions may be dwarfed to degeneracy by poor food and a vitiated atmosphere devoid of sunlight. Tuberculosis is liable to be communicated by city cow-stable milk, by food exposed to germs afloat in the dust of the atmosphere, and in rooms occupied by consumptives. The author urges zeal and care in the protection of the young from such contamination, and in obtaining proper feeding and hygienic surroundings.—*The Sanitarian.*

Metchnikoff on Microbes in the Human Body.—M. Metchnikoff of the Pasteur Institute lectured on the above subject in Manchester, Eng., a short time ago, and in the course of his remarks said that of all the parts of our digestive system, it was certainly the small intestine alone that was indispensable to the continuance of life. And yet in man, who could support himself on food easily digestible, the small intes-

tine was disproportionately fully developed. Instead of having it between eighteen and twenty-one feet long, man could do with one-third of that length. Kakala reported a case in which he had removed almost two-thirds of the small intestine with the greatest advantage to the patient. In one case Körte had removed, together with part of the small intestine, the greater part of the large intestine, leaving only the terminal section. As a result of this operation, the man had been completely cured. He cited other cases of successful surgical operations to prove the uselessness of the large intestine to human beings. In one case the whole of the large intestine had atrophied of itself without operation, in consequence of a fistula, without interfering with the active life of the subject. The sum of all this was that we possessed a voluminous and highly developed organ, the large intestine, which fulfilled no useful function, and bred a very copious and varied mass of microbes, capable of injuring us through their poisons.

The Indigestion of Loneliness.—*The Lancet* discourses lightly but withal instructively upon the sad fate of the solitary being as viewed chiefly from the standpoint of physical health. Of course it is well known that it is not good for man to live alone, nor for the matter of that for woman either. Social communion is in the majority of cases favorable to health and exerts a salutary influence upon the action of the gastric juices. Alexander Selkirk, doubtless, was a man of exceptional temperamental qualities, or he must have succumbed under the mental and physical strain to which he was subjected by his enforced, lonely, prolonged exile on the island of Juan de Fernandez. Our esteemed British contemporary makes the following sage remarks upon the evils of loneliness: "At a time like the present, when the marrying age of the average man of the middle classes is being more and more postponed, the physical ills of bachelordom come increasingly under the notice of the medical man. It is not good for man or woman to live alone. Indeed it has been well said that for solitude to be successful, a man must be either angel or devil. This refers, perhaps, mainly to the moral aspects of isolation, and with these we have now no concern. There are certain physical ills, however, which are not the least among the disadvantages of loneliness. Of these, there is many a clerk in London, many a young barrister, rising perhaps but not yet far enough risen, many a business man or journalist, who will say that one of the most trying features of his unmarried life is to have to eat alone, and a premature dyspepsia is the only thing that ever takes him to his medical man. There are some few happily disposed individuals who can dine alone and not eat too fast, nor too much, nor too little. With the majority it is different. The average man puts his novel or his paper before him, and thinks that he will lengthen out the meal with due deliberation by reading a little with, and more between, the courses. He will employ his mind enough to help, and too little to interfere with, digestion. In fact, he will provide that gentle mental accompaniment which with happier people conversation gives to a meal. This is your solitary's excellent idea. In reality he becomes engrossed in what he is reading, till, suddenly finding his chop cold, he demolishes it in a few mouthfuls; or else he finds that he is hungry, and paying no attention to the book, which he flings aside, he rushes through his food as fast as possible to plunge into his arm-chair and literature afterward. In either case the lonely man must digest at a disadvantage. For due and easy nutrition food should be taken slowly, and the mind should not be intensely exercised during the process. Every one knows that violent bodily exercise is bad just after a meal, and mental exertion is equally so. Wise people do not even argue during or just after dinner, and observation of after-dinner speeches will convince any one that most speakers neither endure themselves nor excite in their hearers any severe intellectual effort. In fact the experience of countless generations, from the red Indian of the woods to white-shirted diners of a modern party, has perpetuated the lesson that a man should not eat alone, nor think much at the time, but should talk and be talked to while he feeds. Most people do not think much when they talk, and talking is a natural accompaniment of eating and drinking. How does it fare with the many solitary women of to-day? No better, we know, than with the men, but differently. Alone or not, a man may generally be trusted at any rate to take food enough (we suppose, of course, that he can get it). With a woman it is different. She is more emotional, more imaginative, and less inclined to realize the gross necessities of existence. Therefore, the woman doomed to dine alone as often as not does not dine at all. She gets dyspepsia, because her digestion has not sufficient practice. A man gets it, because his functions practise it too often in the wrong way. Worst of all, perhaps, is the case of the solitary cook. In the myriads of small flats in London there are thousand of women 'doing' for their solitary masters and mistresses. These women, whose main occupation is to prepare food for others, find it impossible to enjoy, or even take, food themselves. As confectioners are said to give their apprentices a free run of the stock of the shop for the first few days, knowing that it will effectively cure appetite afterward, so the women who are always occupied with buying and preparing food grow unable to use it for themselves. These people suffer from dyspepsia, which is cured if somebody else manages their kitchen for a week, allowing them to take meals without preparing them. It needs no moralist to declare the evils of solitariness. The human being is a gregarious animal. Physically and intellectually we improve with companionship. Certainly it is not good to eat and drink alone. It is a sad fact of our big cities that they hold hundreds of men and women who in the day are too busy and at night too lonely to feed with profit, much less with any pleasure."

The Care of the Wounded in Naval Warfare.—In an article in the *Archives de Médecine*, part of which is quoted in *The Lancet*, Dr. Léo reviews the important question of the removal and accommodation of wounded men in naval warfare. "One may say, without exaggeration," says Dr. Léo, "that as regards regulation and installation, the arrangements for succoring the wounded during conflicts at sea, have not advanced a single step during the past thirty years." Dr. Léo supports the accusation with exhaustive references to official publications and documents, as well as by quotations from several authoritative writers, whose descriptions of existing arrangements for the wounded in particular instances could not be more condemnatory. The problem to be solved is a complex one, bristling with difficulties in every direction. Unless the necessary space is provided in the original plans, when the framework of a vessel is under construction, it is hopeless to expect that on completion she will possess adequate medical and surgical accommodation. The reservation *ab initio* of sufficient room for hospital wards and annexes, and of sufficiently spacious avenues leading down them, is absolutely essential, but, as Dr. Léo observes, it is of equal importance that the installations which have obtained sanction should not be modified subsequently out of all recognition during the armament and equipment of the vessel. In practice unfortunately this is what usually takes place, with most disastrous consequences.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 29, 1901.

DARWIN'S ILL-HEALTH.

IN Darwin's autobiography and in the reminiscences written by his son and in his letters, the reader cannot fail to be struck with the ever-recurring references to the state of his health. From the age of twenty-seven until his death, forty-six years later, there does not seem to have been a day upon which he enjoyed even fair health. W. W. Johnston published recently in *The American Anthropologist* an article treating of this subject, in which is related at some length the history of Darwin's ill health, its nature, and its effect upon his work.

In early life the great philosopher was strong, fond of out-door life and proficient in many forms of sport. He was a man of fine physique, of strong constitution, and inherited from his immediate ancestors on his father's side a tendency to long life. After leaving school he first went to Edinburgh, with the intention of qualifying as a physician, his father's profession. However, he quickly came to the conclusion that he was not fitted for a medical life, and went to Cambridge, where he stayed three years. Up to the end of his university career his health had been excellent.

Upon leaving Cambridge he was appointed to the position of naturalist to H. M. S. *Beagle*, which was then about to start on a voyage of discovery and research. The long train of symptoms which followed him through life dated from this appointment. He was away from England for five years, the greater part of the time being spent in and about South America.

Little is known concerning his physical condition during this period except the few references to the subject contained in his journal. Although Darwin speaks of being ill, he was able to go on with his work and showed very great powers of endurance. Upon his return to England he settled in London, married, and continued to live there for rather longer than five years. His health then became so unsatisfactory that he decided to leave London and to live in the country, where he accomplished the most important part of his monumental literary labors.

Mr. Johnston divides the life of Darwin into four periods, each one characterized by a different condition of health. 1. From birth to the age of twenty-two. He was at this time in excellent health, active-minded, with keen sensibilities, devoted to out-door life and exercise. 2. From the age of twenty-two to twenty-seven—the period covered by the *Beagle* voyage. He was then strong, capable of bearing great physical fatigue, but taxing his mental and physical endurance to the utmost. Rare and sudden illnesses occurred, brought on by unusual strain on mind and body. 3. From his return to England in 1836 to 1872. This period of thirty-six years represents the time of his most severe suffering and of the accomplishment of the greatest part of his work. 4. From 1872 to 1882. A notable improvement in the nervous symptoms, which had made life miserable and work difficult, marked this period. He was less despondent, worked more easily, and we do not read of the distressing insomnia, exhaustion from conversation, indigestion, and other causes of suffering so frequently mentioned in the preceding years. At this time he developed new symptoms, however, which took the place of those enumerated. These were clearly due to atheromatous and senile changes in the heart and vessels. With advancing years angina pectoris and accompanying cardiac exhaustion led to his death in 1882.

The causes of Darwin's ill-health are attributed by Mr. Johnston in the first instance to his voyage in the *Beagle*, brought on by excessive physical and mental strain, to which should be added the hardships and discomforts involved in ship life and the exertions taken in a somewhat unhealthy tropical climate. No doubt the five years spent with the *Beagle* under these conditions sapped Darwin's constitution and sowed the seeds of his subsequent ill-health. He further aggravated the bad state of his health by his pertinacity in continuing at high pressure his work without rest on returning to England. The arduousness of his literary efforts will be better appreciated when it is said that during his lifetime Darwin was the author of twenty-three distinct and important works, not including new editions and reviews, nor the works which he edited and superintended through the press. He also published fifty-one papers and communications to scientific journals.

The conclusions arrived at by Mr. Johnston in regard to the nature of Darwin's ill-health are that he had no organic disease, but that he suffered from a chronic neurasthenia of a severe grade, due to the overstrain of the *Beagle* voyage and also to the life of hard intellectual work begun in 1837 and continued until 1882.

These conclusions are doubtless correct, but one cannot avoid the impression that some of Darwin's symptoms might be ascribed to the hypochondriasis so common to men who use their intellectual faculties to an excessive extent, and lead for the most part an insanitary and sedentary existence. Carlyle is a conspicuous case in point. It should be borne in mind that both these great men reached a ripe old age, and therefore could not have suffered from any serious organic trouble. In the instance of Darwin Mr. Johnston stoutly rebuts such an idea, and asserts that it is shown upon the positive testimony of his son that Darwin's sufferings were real; and that in so calm and well-balanced a mind as that of the author of "The

Descent of Man," it is not reasonable even to assume that imagination may have been a factor in the production of his symptoms. The highly strung nervous organization of Darwin would probably not permit his brain to rest, the result being that the mental strain reacted upon the system, bringing in its wake all the unpleasant functional symptoms which nature inflicts upon those who rebel against her laws. Such, however, are the men who usually do the best work in the world.

THE INSANE IN GENERAL HOSPITALS.

There is no valid reason why individuals afflicted with a mental disease should not be as worthy of care in a general hospital as other sick persons. Yet there has always been a great deal of red tape about the treatment of unfortunates afflicted with mental disorders. The regulations of the prison have been applied in a measure to the admission of the insane to hospitals for treatment. As a result the insane have been placed on a par with criminals, and a stigma has attached itself to legal commitments for insanity. Yet early and careful treatment is as important for disordered mental states as for most somatic diseases.

Dr. Frederick Peterson, the recently appointed president of the New York State Lunacy Commission, has for many years advocated the establishment of wards or pavilions in connection with general hospitals for the early treatment of acute, delirious, and insane patients. In January, 1890, as chairman of a committee of the New York Neurological Society, he formulated the following paragraph in a series of resolutions in relation to the so-called Gallup lunacy bill then before the legislature:

"A clause should be introduced into the bill providing that nothing in the lunacy laws of this State should be construed to interfere with the reception and treatment of acute cases of insanity in chartered general hospitals, in the same manner and under the same conditions as patients suffering from other diseases are there received and treated, provided such hospitals have suitable accommodations approved by the State commission in lunacy."

In a paper on "The Treatment of the Insane Outside of Asylums" in *The Medical News* for March 11, 1893, Dr. Peterson conceived the lines of progress in the care of the insane to be as follows: 1. The opening of special reception wards or pavilions for the insane in general hospitals; 2. The establishment of psychopathic hospitals in large cities; 3. The creation of out-door departments in connection with asylums situated in densely populous districts.

In his address on "Some of the Problems of the Alienist" before the American Medico-Psychological Association, May 24, 1899, he reiterated the idea of the care of the insane in general hospitals. In this address he said that psychopathic hospitals should be established in all cities having a population of from 50,000 to 100,000; and that isolation wards or pavilions for the acutely insane in connection with general hospitals should be provided for the needs of the smaller towns and cities.

It is a pleasure to record that the first modern psychopathic pavilion in this country in connection with a general hospital has already been projected, planned, and constructed on the grounds of the Albany General Hospital. It is now about ready for the reception of its first patients. The credit for the inauguration of this reception hospital for the insane at Albany is probably due to Dr. J. M. Mosher, who, in a paper on "The Insane in General Hospitals" in *The American Journal of Insanity*, vol. lvii., No. 2, gave an outline of what it was proposed to do in that city, together with a plan of the two-story pavilion about to be erected for the acutely insane. The Albany physicians went quietly to work, and secured the grant of space from the General Hospital, and $18,000 for the pavilion from the board of supervisors. The Albany Reception Hospital will accommodate twenty patients.

We have lying before us "An Act to Provide for the Construction and Equipping of a Psychopathic Ward upon the Hospital Grounds of the University of Michigan, and to Appropriate the Sum of Fifty Thousand Dollars Therefor." This bill became a law in Michigan on May 25, 1901. Forty patients are to be provided for, and Ann Arbor will have this additional feature in connection with its chair of psychiatry.

It is evident that the public is awake at last to the needs of the insane, and that the era of early treatment of mental disorders in the city and county jails is now about past. We trust that the readers of this editorial will observe the trend of modern care of the insane, and that the physicians in our larger cities and towns will promptly begin to agitate the question of the establishment of wards or pavilions for these unfortunates in general hospitals, or of separated psychopathic hospitals associated with our medical schools and universities.

THE BACTERIOLOGY OF ACUTE ARTICULAR RHEUMATISM.

Acute articular rheumatism may be defined as an acute, specific, infectious disease, characterized especially by inflammation of one or more joints, and often complicated by endocarditis. There are, in addition, other varieties of arthritis, which also may be complicated by endocarditis, but of different etiology. Further, it seems not impossible that both acute rheumatism and the group of disorders resembling it may be unattended with obvious articular involvement, and exhibit only such manifestations as tonsillitis or endocarditis, together with more or less characteristic constitutional features. Chorea, it is also thought, is in some way related to, if not an actual expression of, acute rheumatism.

Much study has been devoted to the bacteriology of acute rheumatism, and various forms of cocci especially have been looked upon as the etiological factor. One of the most elaborate and complete studies in this connection has been made by Drs. F. J. Poynton and Alexander Paine, who now supplement (*Lancet*, May 4, 1901), an earlier report (*Lancet*, September 22, 29, 1900) with additional data. These investigators found in eight successive cases of acute rheumatism

a diplococcus susceptible of cultivation in liquid media, in streptococcic chains. The organism did not thrive upon ordinary agar or upon serum-agar, and although it could be grown upon blood-agar, it appeared to thrive best in a liquid medium of milk and bouillon rendered slightly acid with lactic acid. On three occasions the organism was isolated in pure culture during life from the blood of patients suffering from acute rheumatic pericarditis. It was obtained also after death from the pericardial fluid. the heart blood, and the valves, and from the throat of a rheumatic patient, as well as from a rheumatic nodule. In five of the eight cases the diplococcus was present in pure culture. Intravenous inoculation of rabbits with pericardial fluid and with pure cultures was followed by polyarthritis and endocardial and pericardial complications, and from the lesions, as well as from the kidneys and from the liver, diplococci were isolated. The micro-organisms were found also in the heart-valves or pericardium in eight other cases of undoubted rheumatic fever, and in the pia mater and brain in a case of fatal chorea. These observations have now been confirmed in eight additional cases. Besides, the organisms were demonstrated in two more nodules, and they were grown in the nodular tissue outside the body in pure culture. Further, a condition believed to be acute rheumatism—namely, polyarthritis, pericarditis, and multiple valvulitis—was induced in a rabbit by intravenous inoculation from that culture. Finally, the chain of proof was completed by isolating the organism in pure culture from the joints of the animal after death.

SOME THERAPEUTIC USES OF THE ACTUAL CAUTERY.

Despite the activity in physiological research displayed in recent years, we are still without a satisfactory explanation for the efficacy of certain therapeutic measures that have long enjoyed successful employment. In treatment especially it is a wise rule to hold fast to that which is good, and, while ever maintaining an open mind, not to be carried away by the enthusiasm attending the introduction of every new remedy. Here, as elsewhere, the safe position is midway between extreme radicalism and extreme conservatism. There can be no doubt that many useful therapeutic measures employed at one time or another have fallen into undeserved neglect, while others of unproved utility are used all too liberally because of their novelty alone. It seems possible, further, that the vast number of drugs, so easy of administration, that have in recent years been evolved have perhaps too largely replaced certain manipulative measures for which no true substitute has been provided. Among these are bleeding by leeches, cupping-glass, or lancet, and counter-irritation by blister, moxa, cautery, setons, and the like.

In a practical address delivered recently before the Hunterian Society, Sir William M. Banks spoke of the neglect of the actual cautery in surgery, and reviewed some of the conditions in which this agency was capable of affording relief. Thus the periostitis and ostitis developing at a late stage of syphilis, and often attended with agonizing, boring pain, will often be remarkably ameliorated by thorough application of the actual cautery at a white heat, the patient being anæsthetized and constitutional medication being of course not neglected. So, too, the actual cautery, conjoined with rest and a properly applied splint, can be employed with great advantage in the treatment of certain diseases of joints, especially the knee-joint, in gouty or rheumatic individuals, resulting from traumatism, when the condition is one of synovitis, with swelling of the articular ends of the bone and thickening and matting of periosteum, fascia, ligaments, and aponeuroses. The use of the cautery is indicated further in the presence of acute inflammatory conditions of the spinal column and the spinal meninges following traumatism. In addition to the foregoing conditions for the relief of which the cautery has been used, Banks recommends its employment in the treatment of cases of pruritus ani of undetermined pathology, attended with exaggerated wrinkling of the skin around the anal orifice and presenting an appearance suggestive of slightly damp, rugose wash-leather. This condition has proved exceedingly resistant to all forms of treatment, but it will usually yield promptly to the application of the cautery.

THE DANGERS OF OPERATION IN CASES OF EXOPHTHALMIC GOITRE.

If operation in cases of exophthalmic goitre is attended with special dangers the fact is not generally known; nor does it seem to be referred to in the literature. It is true that disastrous results occasionally follow quickly upon partial or complete extirpation of the thyroid gland, but these may be attributed in part to the gravity and often the bloodiness of the operation and the danger of complications, and in part perhaps to the secondary effects of the removal of a gland whose importance in the economy has only recently been properly appreciated. The state of intoxication, the condition of the nervous system, and the lowered vascular tension should besides awaken caution in the operation. A case that seems to illustrate the bad effects that may follow operation not involving the thyroid gland in a case of exophthalmic goitre has recently been reported by Mr. T. D. Harris (*British Medical Journal*, May 4, 1901). A woman, forty-six years old, with exophthalmic goitre, presented herself on account of stabbing pain in the left breast of about two weeks' duration. On examination a lobulated mass was felt in the upper part of the gland, which itself seemed inflamed and swollen. The pulse was seldom below 150, irregular and forcible. Tremor was distinct and Graefe's symptom was well marked. The goitre had long been present, and the pulse had been quick for twenty years. Under treatment for one month with potassium iodide and ammonia, and local applications of extract of belladonna and mercurial ointment, the mastitis diminished, but the hard, lobulated mass became more prominent. Removal of the breast was decided upon and carried out, but the patient died sixty-eight hours after the operation, with

great acceleration of the pulse, but without elevation of temperature. The unfortunate outcome is attributed primarily to the condition of the heart, whose rapid and irregular action is referable to dilatation of the ventricle, with thinning of its walls, the situation being aggravated by the effects of the anæsthetic and the unavoidable loss of blood. Of course it would be difficult to prove that death in this case was really due to the presence of exophthalmic goitre, and that the association was more than a coincidence, but in any event the possibility should be borne in mind and suitable precautions be taken under like circumstances if operation should be deemed necessary.

News of the Week.

Medical Society of the State of New York.—Dr. Henry L. Elsner, president of the Medical Society of the State of New York, announces the appointment of his business committee for the coming year, consisting of Dr. Nathan Jacobson, 430 S. Salina Street, Syracuse, Dr. George Ryerson Fowler, 301 De Kalb Avenue, Brooklyn, and Dr. William C. Krauss, 371 Delaware Avenue, Buffalo. All communications referable to papers and scientific communications pertaining to the semi-annual meeting to be held in New York City on October 15 and 16, 1901, and the annual meeting to be held in Albany in January, 1902, should be addressed to the chairman of this committee.

A New Peril of City Life.—Suit for damages was recently brought against the Metropolitan Street Railway Company by a man who claims to have been thrown to the ground and severely injured by an electric shock received while stepping on the slot of the underground trolley road in Second Avenue. The plaintiff's contention is that the ground was partly covered with snow and that the electric current leaked and thus injured him. His complaint says that the company did not use proper appliances to detect the leakage, and therefore it was negligent.

The Surgeon's Right to Use Judgment in Operating.—Judge Kavanagh, of Chicago, ruled a few days ago, in a suit for damages against the Post-Graduate Medical School and Hospital, that in case a surgeon, while performing an operation on a person under the influence of an anæsthetic, finds that another operation, not contemplated before, is necessary, he has the legal right to perform the second operation without waiting to get the consent of the patient.

Dr. Paul F. Mundé has resigned the chair of gynecology in Dartmouth College, which he had held for twenty years, and has been elected by the trustees professor emeritus of gynecology.

Post-Graduate Instruction in Germany.—Classes for instruction especially to medical graduates have been very generally established in the past year or two in the several German universities. These are known as the "medical extension classes," and serve the same purpose as the post-graduate schools long flourishing in this country.

A Gift to the Harvard Medical School.—Mr. J. Pierpont Morgan has offered to give three of the five new buildings to be erected for the use of the medical department of Harvard University. The cost of the buildings will be about $1,000,000. The university was recently presented with the use of a tract of twenty acres by Messrs. Henry and Frank Higginson, who have agreed to hold it in trust until such time as the university can purchase it at the present cost price of half a million dollars. Mr. Morgan's gift, it is announced, is for the prosecution of "applied biological research." One of the five buildings planned for the medical school will be a hospital.

Compulsory Vaccination in Cuba.—A decree has just been issued making vaccination compulsory throughout Cuba. It orders that within four months from August, 1901, all persons who have never been successfully vaccinated must be vaccinated, and that all children shall be vaccinated before they are one year old. Physicians are to be appointed to vaccinate the people under the superintendence of a permanent vaccination commission.

A Chicago Medical School Burned.—The building of the College of Physicians and Surgeons, the medical department of the University of Illinois, was struck by lightning on Tuesday evening and destroyed by the fire which followed.

An Epidemic of Suicides.—It is said that over thirty of the residents of Emporia, Kans., a town of about nine thousand souls, have committed suicide during the past two years. In one day recently three persons attempted suicide, all in the same way. The mayor has now issued an order forbidding the local newspapers to print any further details of suicides or attempted suicides in the town. He says that a veritable mental epidemic exists, and that infection is spread through the accounts in the papers, which he, therefore, characterizes as matter deleterious to the public health, and as such legally suppressible by the public authorities.

Infection through Insects. — Surgeon-General Wyman has issued a general circular to medical officers of the Marine-Hospital service calling special attention to the importance of insects as conveyers of disease. Medical officers are directed to place mosquito nettings over the beds of patients with communicable diseases. Hospitals are to be thoroughly protected by fly screens at all openings, particular attention being paid to the kitchen and dining-room.

Mosquitos and Yellow Fever.—In his latest report of the sanitary condition of Havana, dated June 1st, Dr. W. C. Gorgas, chief sanitary officer, stated that there had been no cases of yellow fever in the city since May 7th, and since March 1st there had been but one death from that disease, this occurring on March 13th. In no other year have the conditions as to yellow fever ever approximated this. He said, regarding this: "I cannot but hope that this exceptionally good condition is in great part due to the large amount of labor and money we are expending in the destruction of mosquitos; and the circumstances of the

case point in the same direction. Since March 8th, outbreaks of yellow fever have occurred twice. The first time, April 21st and 22d, we had two cases; and again on May 6th and 7th, four cases. Each time the infected houses, and three or four contiguous houses on every side of the infected house, were carefully gone over. Every room in each of these houses was closed and sealed, and insect powder burned in them at the rate of 1 pound to 1,000 cubic feet. All standing water was drained away, where possible; and oiled where it could not be drained. The results look as if the focus of infection, at that particular point, had been eradicated. In the case of the patient taken sick March 8th after our disinfection, we went forty-two days till the next case. Then an outbreak occurred, April 21st and 22d. We again disinfected; and went fifteen days till the next cases, May 6th and 7th. We again disinfected; and have gone twenty-four days without a case. I am more particularly impressed by these figures, as we commenced our systematic destruction about the middle of February."

Dr. Frank L. Christian, formerly a house physician at Bellevue Hospital and more lately medical officer of the Eastern District Reformatory, has been appointed medical superintendent of Elmira Reformatory, at a salary of $3,500 per annum, with a residence.

Raising of the Quarantine against Cuba.—Dr. James D. Glennan, surgeon of the Marine-Hospital service at Havana, has recommended the raising of quarantine on passengers from Cuba to all ports north of Norfolk. This recommendation is based upon the fact that yellow fever practically exists no longer in the island, thanks to the medical officers of the United States army. At present non-immune passengers from Cuba are held at quarantine at New York a sufficient period to make a total of five days from Cuba. In the case of the faster boats this means a detention here of from twenty-four to thirty-six hours.

A Collecting Agency Sues Physicians.—Several Brooklyn physicians were sued recently for $25 each by a debt-collecting agency. The suits were based upon a clause in the contract according to which the physicians were led to promise to put into the agency's hands claims, amounting in the aggregate to $150, against at least thirty debtors living in this State. These claims were to be sent to the agency within twenty days, and with them were to be sent two two-cent postage-stamps for each name on the list. It was agreed that failure to comply with any of these stipulations should subject the signing physician to a penalty of $25. The defence was that the contracts were signed under a misapprehension of their provisions.

An Epizootic in New York.—An epidemic has attacked the horses of this city during the past two weeks, the nature of which has not been definitely determined. The symptoms are fever (102° to 105° F.), cough, loss of appetite, and pronounced weakness amounting in some cases almost to collapse. The veterinarians say that it is the most serious epidemic affecting horses which New York has seen since 1874. The present disease is much less severe, however, than that was, for though some 40,000 or 50,000 horses have been attacked and temporarily disabled, few deaths have occurred. In 1874 thousands of horses died during the six weeks that the disease prevailed. Several of the cities in the neighborhood of New York have also been visited by the same epidemic.

The American Institute of Homœopathy.—The election of officers in the American Institute of Homœopathy, which held its annual meeting at Richfield Springs last week, resulted in the choice by a majority of sixty votes of the following: *President*, Dr. James C. Wood, of Cleveland; *Vice-President*, Dr. Edward Beecher Hooker, of Hartford, Conn.; *General Secretary*, Dr. Charles Gatchell, of Chicago; *Treasurer*, Dr. Thomas Franklin Smith, of New York; *Recording Secretary*, Dr. Wilson A. Smith, of Chicago.

The British Congress on Tuberculosis.—Announcement is made that this important congress will be held in the Queen's Hall, London, from Monday, July 22, to Friday, July 26, 1901. The work of the congress will be divided among four sections as follows: State and Municipal, under the presidency of Sir Herbert Maxwell; Medical, including Climatology and Sanatoria, Sir R. Douglas Powell; Pathological, including Bacteriology, D. Sims Woodhead; Veterinary (Tuberculosis in Animals), Sir George Brown. The section meetings will be held daily from Tuesday to Friday at 9:30 A.M. On the evening of Monday, July 22d, the opening day of the congress, a reception will be held by the organizing committee in the Queen's Hall, when the band of the Royal Engineers will be in attendance. On Tuesday, the 23d, Professor Koch will address a public meeting in St. James' Hall, and in the evening a reception will be held by the Lord Mayor in the Mansion House. On Wednesday afternoon, the 24th, Professor Brouardel, of Paris, will address a public meeting in St. James' Hall at 3 o'clock, and from 4:30 to 7 P.M. the ladies' reception committee will give a garden party in the Royal Botanic Society's Gardens. On Thursday afternoon, the 25th, the Earl and Countess of Derby will give a reception, and on Friday afternoon Sir J. Whittaker Ellis will entertain members and their friends at a river party at Richmond. On Saturday, the 27th, excursions will be arranged to sanatoria and other places of interest, and in the afternoon the Duke of Northumberland will give a garden party at Syon House. During the period of the congress some of the largest private houses in London with interesting collections of pictures will be thrown open to visitors. Quite a large attendance of American physicians is expected. Those who intend taking part in the congress should send their names, with the membership fee of $5, to Dr. St. Clair Thomson, 20 Hanover Square, W., London.

Enucleation of Ovarian Cysts.—Dr. Edward N. Bush, of Baltimore, writes that this operation was first suggested by the late Dr. J. F. Miner, of Buffalo, and not Dr. Mynter, of Buffalo, as was stated in the abstract of Dr. C. D. Palmer's paper in the report of

the American Gynecological Society, on p. 1013 of the MEDICAL RECORD. "The operation," he writes, "was first suggested and made by the late Dr. J. F. Miner, of Buffalo. Dr. Miner contended that the operation, with modifications suggested by the case in hand, was applicable to all forms of ovarian cyst, and made the operation repeatedly. I am not aware that Dr. Mynter ever attempted it."

Koch Still Believes in Tuberculin.—Dr. Robert Koch states in the *Deutsche medicinische Wochenschrift* that tuberculin has been used by a Dr. Goetsch in the treatment of uncomplicated tuberculosis for the past two years with uniformly successful results.

The Good Samaritan Dispensary.—An examination will be held this summer for the position of attending surgeon to the department of diseases of the skin in this institution. Applicants must have had hospital experience and possess a practical conversational knowledge of German.

The Plague has reappeared in Honolulu. Major Blair D. Taylor, of the army medical department, reports that there were four deaths from bubonic plague at Honolulu from May 29th to June 9th. His report says that the Honolulu board of health has taken every precaution to segregate the inhabitants of infected houses and disinfect them, and the president of the board believes that he has the situation well in hand. At Hong-Kong the disease has broken out in virulent form, and every port in the Orient has quarantined against that place. A United States transport, having on board one hundred and eighty soldiers and sixteen officers, returning from the Philippines, was detained at Nagasaki on account of the death from plague of a Chinese fireman. At Hong-Kong since the first of the year seven Europeans and five hundred and forty-two natives have died of the plague. A British steamer is in quarantine at San Diego, Cal., having lost six of her crew from plague during the voyage from Hong-Kong. One death occurred before Honolulu was reached, and five between that port and San Diego. The cases were not confined to any part of the ship, various members of the crew and one steerage passenger being among those attacked. Many dead rats were found in the ship.

A Medical Excursion to London and Paris has been arranged for the benefit of medical men in this country and Canada who are desirous of attending the forthcoming Tuberculosis Congress in London and the annual meeting of the British Medical Association. The steamer *Zeeland* will leave New York on July 10th, arriving at Cherbourg on the 18th. The party will proceed to Paris, and after spending two or three days there will cross the Channel to England, arriving in London in time for the opening of the Tuberculosis Congress. The meeting of the British Medical Association will be held immediately afterward at Cheltenham, and the party will have the option of returning by the *New England*, which will leave Liverpool on August 1st, and is timed to reach Boston on the 8th, or by the Cunard steamer *Umbria*, which will leave Liverpool on August 3d, and is due in New York on August 10th. The cost of the trip will be $238 or $260, according to the date of return. The arrangements of the trip are in the hands of Henry Gaze & Sons, New York.

An Australian Medical Mayor Honored.—Dr. John Graham, Mayor of Sydney, N. S. W., was knighted by the Duke of Cornwall on the occasion of the latter's visit to that city. Sir John Graham is also a member of parliament for New South Wales. During his term of office as mayor he has made special efforts to improve the sanitary condition of his city.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ended June 22, 1901. June 17th.—Dr. H. M. Tolfree appointed assistant surgeon from June 14, 1901. June 18th.—Surgeon C. F. Stokes ordered to the *Solace* upon arrival in the United States. Assistant Surgeon R. B. Williams ordered to the *Kearsarge*, June 24th. June 20th.—Assistant Surgeon F. M. Furlong detached from duty at Guam and ordered to the *Solace* for transportation home. Assistant Surgeon R. K. McClanahan detached from the *Culgoa* and ordered to the *Vicksburg*. Assistant Surgeon D. B. Kerr detached from the *Vicksburg* and ordered to the *Culgoa* to wait orders en route.

Obituary Notes.—DR. WILLIAM LEONARD WORCESTER, pathologist to the Danvers, Mass., Hospital for the Insane, died in that institution on June 9th, at the age of fifty-six years. The cause of his death was septicæmia. He was born in Chelsea, Vt., his father being Dr. Ezra C. Worcester. He was a graduate in arts of Dartmouth College in 1869, and in medicine of the Medical Department of the Columbia University, Washington, in 1873. He practised for a while in Burlington, Vt., and then went to Kalamazoo, Mich., where for eleven years he was assistant physician at the insane asylum. Following that he was for six years assistant superintendent of the hospital for the insane at Little Rock, Ark. In 1895 he was appointed pathologist at the Danvers hospital. One of his brothers is Prof. Dean C. Worcester of the Philippine Commission, now in Manila.

DR. E. E. WAITE, of New Bedford, Mass., died in that city on June 20th, at the age of forty-eight years. He was a graduate of the New York University Medical School in 1877. He was at various times physician to the overseers of the poor, city physician, and member of the New Bedford board of health. A widow and one daughter survive him.

DR. GEORGE HOSMER MAGNESS died at his home in White Plains, N. Y., on June 25th, at the age of fifty years. He was born in this city and was graduated from the Bellevue Hospital Medical College in the class of 1876. He was a member of the Westchester County Medical Society and was president of the White Plains board of health.

DR. JAMES W. E. ROBY, of Brooklyn, died on June 25th at the age of thirty-eight years. He was born in this city and was graduated from the University Medical College in 1887. A widow survives him.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 20, 1901.

The Home Treatment of Tuberculosis vs. The Climatic Treatment.—Edward O. Otis, while upholding the benefits of such climates as Colorado, etc., believes that so many sacrifices have to be made for the gain that it is a debatable question whether the gain is worth the price paid. Exile from familiar surroundings and friends, the fatigue and expense of a long journey, the necessity for acclimatization (and reacclimatization when the patients return home), are all very valid objections to the climatic treatment. Any region whose climate permits one almost continuously to remain out of doors in pure air, is a favorable one for the hygienic-dietetic treatment. Sanatorium treatment would seem to be better than home treatment because of the greater power and personal influence exerted by the physician over his patients. Still it is difficult to compare the two, as conditions as to stages of the disease, class of patients, detail of treatment, etc., vary so greatly. On the whole, it must be a source of congratulation to all interested that the prospects of success in the home treatment appear so auspicious, for it is a very small minority of the tuberculous who are able or willing to travel far afield for a resort in which to take the cure.

Puerperal Insanity.—Edward B. Lane does not deny that insanity occurs in conjunction with the puerperal state, nor that the puerperal condition is an exciting cause, but he does not recognize a distinct type of mental disease the immediate result of the puerperal condition. Heredity may play an important part, but he questions whether it is more potent in these cases than in insanity in general. As to statistics, investigations in Boston show that, as a matter of fact, insanity associated with childbirth occurs only one-half as often as it does among women in general at the child-bearing age. To use the terms of the insurance actuary, it would be a good risk to insure a pregnant woman against insanity, or at least against commitment for insanity. The author believes it to be demonstrated that the puerperal condition is not an important factor in the causation of insanity, and cites a number of cases to illustrate his point.

A Case of Marked Cyanosis Difficult to Explain.—Sylvester F. McKeen reports the case of a man aged fifty-three years, of excellent family and personal history, except that twenty years ago he had an attack of dyspnœa which laid him up for eight days, with similar attacks at intervals of six months to two years. He has now had cyanosis for a year and a half. It came on after an attack of dyspnœa and persists, often increasing suddenly. He has attacks of blurring of vision and vertigo and sweating; also of diarrhœa. Physical examination showed extreme cyanosis of face, hands, and feet. No condition was found in any organ to account for the abnormality.

Medical News, June 22, 1901.

Psychic Epilepsy, with the Report of a Case.—J. W. Courtney states that to establish the diagnosis of psychic epilepsy frequently requires a great deal of acumen combined with endless patience and pertinacity. Often are epileptics put on trial for various criminal acts for which they are not responsible and of which they have not the slightest memory. Alcohol as a factor in the production of psychic epilepsy is one of paramount importance. The case reported is one of intellectual petit mal and is of traumatic origin. The patient is an unmarried man aged thirty-three years. Several years after a fall, when he thinks he struck his head, he began to have "fainting" spells, during which his mind was a blank. On one occasion he remembers going into a saloon and asking some one to drink with him, but does not remember getting up to the bar. Several hours later, when he had become conscious, he found himself arrested for drunkenness. With regard to this attack, either he did actually take a drink which precipitated the attack, or the attack came on just as he started to take the drink. If the latter is true, then it can be easily understood that he himself believed, when he realized that he was under arrest, that he had actually taken the drink and become intoxicated. In another attack he was asked to sign a promissory note for ten thousand dollars, which he did. When he read the note aloud, he called the sum ten dollars. On being questioned, he said he meant to sign the note. Five minutes after, he remembered nothing about the note. A half-hour after the onset of the attack the patient was almost fully conscious and remembered nothing whatever about the attack or anything connected with it. The forensic importance of this incident can easily be appreciated.

A Study of Some Complications and Sequelæ of Typhoid Fever.—H. A. Hare and H. R. M. Landis state that croupous pneumonia is a fairly frequent and serious complication of typhoid fever. Pleurisy is not rare. Hypothermia is very common. Hyperpyrexia occurs in the septicæmic type of the disease. Among skin affections which have been noted in this disease are the typical rose rash, herpes labialis, morbilliform rashes, rubeoliform eruption, sudamina, miliary eruptions, urticaria, pemphigus, ecthyma, erysipelas, and purpura. Albumin in the urine is usually a result of the eliminations of the toxins. Hæmoglobinuria is extremely rare. Convulsions occasionally develop. Bulbar paralysis, tetany, and acute ascending hemorrhagic myelitis have been noted but are unusual. Various lesions of the alimentary canal have been reported, *e.g.*, gangrenous stomatitis, glossitis, stricture of the œsophagus. Perforation is most commonly seen in the third week. The most frequent time of hemorrhage is during the second or third week. Nearly every patient with perforation will probably die without operation, but the great majority of those having hemorrhage recover. A number of cases have been collected in which the patients showed every evidence of typhoid fever, and yet at post-mortem no intestinal lesions were found. Involvement of the arteries is far more rare than disease of the veins. Phlebitis is the most common lesion of the vascular system. The most notable fact connected with the blood is the progressively increasing number of the colorless cells following perforation. The typhoid bacillus in the blood has been demonstrated a number of times after death, but very seldom during life. The Widal reaction in recent reports has been present in from ninety-eight to ninety-nine per cent.

Obstipation.—Sterling B. Taylor defines obstipation as an obstructive costiveness which must be differentiated from functional costiveness, intentional, habitual delay of bowel movement, and constipation. It is far more common than is generally believed. It is dependent upon some mechanical or foreign interference situated in the rectum or sigmoid flexure. It may be due to: (1) Compression from without; (2) blocking up of the lumen of the canal; (3) constriction due to disease of the gut wall; (4) hypertrophy of the normal rectal valves. Among the symptoms of hypertrophy of the rectal valves are: Chronic irregularity of bowel movement; frequent, partially successful attempts to evacuate the bowels; stool flattened laterally; an inordinate desire for defecation; a feeling of distention over the colon; inability to pass gas freely; discharge of mucus; headache, melancholia, neurasthenia, etc.; fitful appetite. Treatment may be palliative, massage, enemas, etc. Radical treatment consists in a division of the free border of the valve.

Philadelphia Medical Journal, June 22, 1901.

A Case of Severe Anæmia with Changes in the Spinal Cord.—William E. Hughes and William G. Spiller report this case. The patient was a man aged sixty-three years, his chief complaint being shortness of breath and swelling of the feet and legs. The family history was negative. The pulse was slow and full but of very low tension. The heart was slightly enlarged, the apex beat could hardly be felt, and there was a systolic apex murmur, transmitted into the axilla. Autopsy showed dark fluid blood and a few currant-jelly clots in the heart cavities. The cardiac muscle was dark reddish-brown. In the left papillary heart muscles was a distinct yellow mottling showing through the endocardium. The spleen was of moderate size with thin and light-colored capsule. Its parenchyma was soft, pulpy, and easily scraped. The sclerosis in the spinal cord was most pronounced in the upper thoracic and cervical regions, and was more intense in the left lateral column than in the right in these regions. It was diffuse here. In the posterior columns the degeneration was most noticeable in the ventral portion. The anterior columns were more nearly normal than the other portions of the white matter of the cord, but the neuroglia was proliferated somewhat here also. The anterior and posterior roots appeared to be normal. The crossed pyramidal tracts were degenerated as far as the sacral region, the left more than the right. In the lumbar region the posterior columns were slightly sclerotic. In the medulla, the right anterior pyramid was much degenerated, but the left appeared to be normal. The right pyramidal tract above the decussation was degenerated, the left intact. The nerve-cell bodies of the cervical and lumbar regions were not distinctly abnormal, but some were intensely pigmented. The blood-vessels had much thickened walls.

What I Have Learned from One Hundred and Sixty-One Operations for the Relief of Senile Hypertrophy of the Prostate Gland.—Orville Horwitz concludes that success following the Bottini operation depends on having perfect instruments, a good battery, the necessary skill, and the employment of a proper technique. In suitable cases the Bottini is the safest and best radical operation thus far advised for the relief of prostatic hypertrophy. It is often very efficacious in advanced cases of obstruction as a palli-

ative measure, rendering catheterism easy and painless, relieving spasm, lessening the tendency to constipation, and improving the general health. It is especially valuable in the beginning of obstructive symptoms due to hypertrophy of the prostate gland, and may be regarded as a means of preventing catheter life. It is indicated in all forms of hypertrophy except when there is a valvular formation, or an enormous overgrowth of the three lobes, associated with tumor formation, giving rise to a pouch, both above and below the prostate gland. When the bladder is hopelessly damaged, together with a general atheromatous condition of the blood-vessels, associated with polyuria, results are negative. Pyelitis is not a contraindication to a resort to the operation. The character of the prostatic growth has no bearing on the results of the operation.

American Medicine, June 22, 1901.

The Nervous Exhaustion due to West Point Training.—Charles E. Woodruff states that it is an error to rate scholarship as military ability. To keep a child, aged fourteen years or less, two hours on a single recitation is said to be a heartless violation of all mental laws, and the same can be asserted of the long recitations at West Point. In addition, the cadet, when through his work at the blackboard, must face about and stand at the military attitude of "attention," which is such an unwholesome strain that they now and then feel faint and have been known to go to hospitals as a result of this exhanstion. According to Ellis, "The amount of work performed by the cadet is prodigious. Scarcely a moment is wasted. Under the rigorous discipline, which taxes mental and physical capacity to the utmost for six days in every week, with only a slight loosening up on the seventh, the West Point cadet is always, barring accident, in perfect physical condition." It is impossible for cadets to get more than eight hours of sleep in winter and seven and one-half in summer. The dread of failure is another cause of exhausting strain. The real fault is a system which demands of the human brain three times as much as it can do. The friends of West Point should insist upon the uprooting of evils and modernizing its methods.

Atypical Pneumonia and Pulmonary Tuberculosis.—W. H. Bergtold writes: Be suspicious of an atypical pneumonia. Every case of unusual pneumonia should be suspected and put under surveillance until proved not tuberculosis. There is little excuse for allowing a case of atypical pneumonia to go many weeks, even days, unrecognized, with our present methods of diagnosis, including examination of the blood and of the sputum for tubercle bacilli and pneumococci, the biological and tuberculin tests, and the ordinary methods of chest examination. One of the chief points in the war against tuberculosis is to make an early diagnosis. The sooner the disease is detected, the better are the patient's chances of recovery. In his own cases of pulmonary tuberculosis, the author in one series of one hundred and ninety-three cases found that thirteen per cent. gave a history of previous "so-called" pneumonia, all of suspicious type, varying from one showing no signs or symptoms of croupous pneumonia except fever and consolidations, to others atypical only in one or two ways, *i.e.*, altogether without expectoration, or long continued with no crisis. It is reasonable to suspect, then, that many cases of croupous pneumonia end in pulmonary tuberculosis.

Journal of the American Medical Ass'n, June 22, 1901.

The Value of Calcium Carbide in the Treatment of Inoperable Carcinoma of the Uterus.—I. C. Chase reviews the literature of this remedy and concludes as follows: (1) The mass of the literature on this subject is misleading. (2) The originators of the treatment were ignorant of the real action of calcium carbide, and had insufficient clinical experience to pass judgment on its value. (3) Acetylene has no effect on protoplasm sufficient to support a theory of any specific annihilative action on carcinomatous cells. (4) Acetylene has no escharotic effect. (5) Acetylene has no bactericidal action upon pathogenic bacteria or the bacteria of putrefaction. (6) The principal action of calcium carbide results from liberated quicklime. (7) Lime is not a rational caustic to select, if one is desired, because of its superficial action, the character of the necrosis, and tendency to promote hemorrhage. The metallic salts are more styptic, and their action may be better graduated by proper selection. (8) The amount of heat evolved may be sufficient slightly to cauterize the tissues. In most cases it has slight therapeutic effect save counteracting the tendency to hemorrhage and promoting contraction. (9) The heat of the actual cautery promises better results because of the firmer cicatrices, resisting carcinomatous invasion, and more complete contraction of the wound. (10) Calcium carbide is open to the same dangers as are other caustics when improperly or too zealously applied: those of producing its corrosive action in the wrong place, fistulæ, perforation, and fatal peritonitis or occlusion of the ureters. (11) The treatment does not reduce odor or hemorrhage, nor give more comfort to the patients than other rational lines of treatment. (12) The claims of its advocates have not been realized in experience. There is no evidence in theory or practice warranting the conclusion that calcium carbide could ever cure a case of really inoperable cancer of the uterus. (13) The facts regarding the subject should be more widely disseminated to expurgate medical literature and to avoid false expectations and fatal delays in operable cases.

The Diagnosis of Diaphragmatic Hernia.—E. Fletcher Ingals relates the history of a case of supposed diaphragmatic hernia in a man aged twenty-nine years. Several other physicians who examined him were of the opinion that the case was one of pneumothorax. A table of differential diagnostic signs between the two conditions is given but is too long to be reproduced here. The literature of the condition is briefly reviewed. These cases are rarely made out during life. Some three hundred have been reported, mostly from autopsy records. The affection possesses many signs and symptoms in common with pneumothorax, like which it causes distention of one side, diminished motion, tympanitic resonance, and feeble or suppressed respiration with metallic tinkling. The most important factors in the differentiation of non-strangulated cases are: (1) That in pneumothorax the metallic tinkle is heard only with respiratory movements or upon shaking the body, while with the hernia it occurs independently of these movements and is associated with rumbling or gurgling of gas in the stomach or bowels which have escaped into the pleura. (2) The displacement of the heart, which in pneumothorax remains practically constant, in diaphragmatic hernia may vary with the varying contents of the stomach or bowels, as when the patient is fasting or soon after eating or drinking freely. The retraction of the abdomen may prove of some value as a sign, and the symptoms of obstruction will be of the utmost importance if strangulation occurs.

Interesting Throat Paralysis in a Case of Locomotor Ataxia of an Irregular Form.—J. E. Rhodes reports the case of a railroad employee aged thirty-five years. His ataxia symptoms began about two years before he was seen by the author. The latter found the left side of the palate relaxed and not responsive to irritation by the probe. The right vocal cord was stationary in the median line, there being a paralysis of the right posterior crico-arytenoid muscle. Special ataxia symptoms were ptosis of the right eyelid and divergent squint of the right eye.

Morphinism; an Unusual Case.—W. E. Taylor reports a case, the interest of which lies in the fact that the patient, a man aged forty-five years, who had been addicted to the habit for sixteen years and had used as high as thirty grains daily, broke off of his own accord without medical or other treatment excepting certain simple domestic measures.

Spasm of the Glottis and Œsophagus in Adult Life.—I. D. Brose reports two cases. In the first the progress of the case showed that irritation of the nerves was set up by a carcinoma of the lower end of the œsophagus and of the stomach. In the second, the cause was probably irritation from apical tuberculous deposit.

New York Medical Journal, June 22, 1901.

Syphilitic Fever, with a Report of Three Cases.—T. B. Futcher says that the fever of syphilis may occur three or four weeks before the secondary eruption, may immediately precede or be coincident with the eruption, or finally may occur at any time during the secondary or tertiary stage. It may take the form of a mild continuous pyrexia with a general range of 101° F.; it may be a definite intermittent fever with morning drops below normal and evening exacerbations; or, finally, it may appear as a definite intermittent fever. The following headings of the three cases reported show some of the difficulties attending the diagnosis: Case I.—Syphilitic fever of remittent and intermittent type, commencing at least twenty-seven days before the appearance of the secondary eruption. Fever ushered in by a chill, followed by sweating. Case II.—Syphilitic fever of a remittent and intermittent type which for weeks was suspected of being typhoid fever and treated as such. Diagnosis established by the discovery of periosteal thickening over the clavicles and by cessation of the fever after the beginning of treatment with potassium iodide. Case III.—Syphilitic fever, characterized by intermittent chills with fever, and treated first as a case of malaria. Fever occurred twenty-nine years after the primary infection and yielded readily to antisyphilitic treatment. The author concludes as follows: (1) In all cases of fever of obscure origin the possibility of it being syphilitic should be borne in mind. (2) Experience has shown that physicians of reputation, as well as those of limited experience, are prone to mistake the condition for one of

the acute specific fevers. (3) The affections for which syphilitic fever is most often mistaken are malaria, typhoid fever, tuberculosis, sepsis, and occasionally rheumatic fever. (4) The fever may occur as early as four weeks previous to the appearance of the secondary skin eruption, or, what is of greater importance, late in the disease after tertiary manifestations have existed probably for years. In Case III. it occurred twenty-nine years after the primary lesion. (5) The fever may be continuous, remittent, or intermittent. The remittent type is regarded as the most frequent form in the fever of invasion. The fever is often associated with chills and sweating. (6) Careful examination of the long bones and viscera for evidences of tertiary lues should be made in all cases of fever of obscure origin.

An Introduction to the Psychological Study of Backward Children.—W. B. Noyes classes mentally defective children as follows: (1) Those in whom the faculty of perception is deficient; (2) those who in spite of possessing all the special senses and power of perception lack the power of attention; (3) those possessing disease or defect of the will; (4) those deficient in the higher or cognitive powers of the mind, the reasoning faculties; (5) those deficient in memory, and (6) those morally defective. There is in addition a large class showing mental stupidity, which is the simplest term for uniform mental deficiency affecting the different mental faculties at the same time. Such children, though possessing special senses, do not really perceive. Attention, volition, reason, and moral faculties are not and cannot be developed to any great extent. This condition in its milder degree is stupidity; in its more pronounced degree dementia.

Inguinal Bubo as a Complication of Malarial Fever.—A. C. Smith, of the Marine-Hospital service, records a group of cases of bubo associated with malarial fever, being generally non-suppurating and the fever being of the æstivo-autumnal type, though not invariably so. The bubo occurred without suspicion of venereal infection, and was clearly secondary to the fever and dependent upon it.

The Lancet, June 15, 1901.

The Feeding of Diphtheria Patients, with Special Reference to Children and Severe Cases.—R. G. Kirton enumerates four methods, by mouth, nasal tube, rectum, and subcutaneously. Contraindications to mouth feeding are inability to swallow owing to pain or faucial swelling, regurgitation, entrance of ingesta into the larynx, struggling on the part of the patient, and vomiting. The latter may be continuous from beginning to end of the disease, may commence about the middle or the end of the second week, or may be deferred for some weeks. For mouth-feeding milk is to be mainly relied on. Patients with regurgitation should be fed on jellies, eggs made into a paste with bread crumbs, etc. Nasal feeding may be required owing to (1) inability to swallow from regurgitation, paralysis of muscles of deglutition, etc.; (2) coughing on feeding, due to entrance of food into the larynx, and this especially in tracheotomy cases; (3) patients who vomit when fed by the mouth, but do not when fed through the nose; (4) cases exhausted by mouth feeding, but not when nasal-fed (among these must be numbered cases in which mouth-feeding takes a very long time); and (5) moral effect. These suggestions apply to children who refuse food though well able to swallow. One nasal feed is often sufficient. Rectal feeding should be resorted to when feeding by the mouth or nose fails or is insufficient. The following are the chief conditions in which it is required: (1) Vomiting; (2) great difficulty in passing the nasal tube from various causes; (3) when nasal feeding acts harmfully on the patient, owing to fright, struggling, or other cause; and (4) epistaxis caused by the passage of the nasal tube. Finally, subcutaneous injections may be made of sterilized horse-serum or saline solution. Horse serum should be used when the amount of nourishment taken by the stomach or rectum, or both, appears to be insufficient to support life. Sometimes it is used as the only means of feeding patients owing to continued vomiting and diarrhœa. It should be injected into the loose subcutaneous tissues of the trunk. If given over a prolonged period, from 20 to 40 c.c. are often as much as it is advisable to inject daily. As a rule, patients submit to its injection well, and Kirton has occasionally noticed that children who have become cyanosed on attempting to nasal-feed, have been injected without any untoward effect. As far as he knows, the only indication against the use of these injections is hemorrhage into the subcutaneous tissues adjoining the site of injection.

Scarlatinal Infection; an Inquiry and an Illustration.—J. B. Pike says that the pathogenic germ of scarlet fever appears to require moisture for its development, and, this being the case, it seems somewhat strange that dry exfoliated epidermis should have received so much credit as the potential in scarlatinal infection. Latterly more attention has been paid to nasal discharge, and pus from the middle-ear is also suspected. This being granted, the question arises, How long can these discharges convey specific scarlatinal infection? Can scarlet-fever microbes lurk insidiously in hiding? Certainly the middle-ear and mastoid cells form excellent quarters for the secret dwelling, if the germs can lie there quietly, without resentment of the tissues. If they can do so for a long or indefinite time we must enlarge our view of the infective period of scarlet fever. Isolation can hardly be indefinite, but if we recognize an ear discharge occurring even a year or more after scarlet fever as possibly or probably infectious, something may be done to prevent the spread of the disease. Another interesting question which is suggested by a reported illustrative case is this: Is a secondary auto-infection possible from scarlatinal poison lurking in the cavities of the temporal bone? Clinical experience is given tending to confirm the foregoing suggestions.

The Treatment of Puerperal Eclampsia by Saline Diuretic Infusions.—The following rules are given for the application of this method by Robert Jardine, who strongly commends it and states that his experience is leading him to give up antispasmodics, and also that in his opinion morphine lessens excretion from the kidneys and is not therefore devoid of danger. The infusions are given under the breast or into the abdominal wall. A medium-sized Potain's trocar and cannula with three or four feet of tubing and a funnel is the apparatus to be used. The apparatus should be sterilized and the skin thoroughly cleansed. From one to three pints can be run in under the breast in a few minutes. The puncture should be covered with strapping. Tablets are used of acetate and chloride of sodium, one drachm in each. One of each should be added to each pint of sterilized water at a temperature of 104° F., as it cools somewhat in the tube. With ordinary precautions there is no fear of sepsis. The author has given over two hundred infusions and has never seen any bad effects. There is considerable tension in the part, but absorption is so quick that this is soon relieved. If necessary the infusion may be repeated several times. As soon as the patient can swallow milk should be freely administered.

Sulphur in the Treatment of Dysentery.—The use of this remedy is commended by G. E. Richmond, who says it is especially serviceable in young adults of vigorous constitution. He finds that it lessens diarrhœa and tenesmus, lowers pulse and temperature, and generally improves the patient's condition. He advises the giving, every four hours, of a powder composed of gr. v. Dover's powder combined with gr. xx. sublimed sulphur. The dose is lessened as soon as the stools become less frequent. It does not as a rule give rise to much trouble from flatulence, and it tends to diminish the unpleasant smell from the stools, acts as an antiseptic, and encourages healing of intestinal ulcers.

Pure Urea in the Treatment of Tuberculosis.—Henry Harper relates the histories of five cases in which the administration of pure urea in four daily doses of gr. xx. each led in conjunction with other measures to surprisingly good results. His opinion is that urea is a constructor or builder-up when given in this disease. This view is forced upon him by his observation of how much better his patients are when eating liver, kidney, and brain (all substances rich in urea) in conjunction with urea taken by the mouth.

British Medical Journal, June 15, 1901.

The Surgical Treatment of Typhoid Fever.—T. J. Maclagan declares that typhoid fever is a disease of the abdomen rather than a fever, when considered as to its surgical aspects. The most serious complication of typhoid fever is perforation of the bowel. All depends on early diagnosis of the accident and prompt surgical interference. The three chief indications of perforation are pain in the lower part of the abdomen, diminished abdominal respiration, and rigidity of the abdominal walls. Any one of these showing itself suddenly toward the end of the third week points to perforation; their combination makes it a certainty. Cases of hemorrhage should be especially watched. Another class of cases is that of retained sloughs. In most cases of typhoid, the sloughs and fetid discharges which pass from the small to the large bowel are carried along without delay and evacuated. In some cases they are retained in the large bowel, especially the cæcum. If the case is desperate the cæcum should be opened under local anæsthesia, and the poisonous contents find direct exit. There should be no unnecessary delay, but as soon as there is evidence of interference with the action of the diaphragm, and the long tube fails to give relief, the cæcum should be opened.

A Case of Typhoid Arthritis Proper.—John J. Buchan reports the case of a boy aged eleven years, who was admitted to the hospital on the sixteenth day of illness. Four typical rose spots were seen. The spleen, although not

palpable, on percussion came forward to the anterior axillary line. The abdomen was somewhat distended. Widal's test was positive on the eighteenth day of the disease. The patient complained of pain in the left elbow-joint. Later it was aspirated and clear serous fluid was withdrawn which proved sterile. The local symptoms disappeared for a time, but later returned, when a second aspiration was performed, and this time a purulent fluid was drawn off. This fluid contained many streptococci and fewer staphylococci. Careful search did not reveal the bacillus typhosus nor the bacillus coli communis. Neither the boy nor any of his near relatives had suffered from any manifestation of rheumatism previously; this joint affection was almost wholly confined to one joint; none of the commoner complications of rheumatism were present, and the affection became suppurative. The fluid did not become purulent till almost a fortnight after the first aspiration.

On Anæmia in Typhoid Fever.—Thomas Houston, after giving the blood counts taken at various stages in a case of typhoid fever, notes that: The leucocytes per cubic millimetre are always below the normal, and show a gradual decrease in number, except in two instances in which an inflammatory complication intervened. The inflammatory increase in leucocytes is not so pronounced as it is in slight cases of suppuration. It seems evident that the leucocytes in typhoid fever react normally to inflammatory toxins, but this reaction is to a large extent masked by the dilution of the blood. The fall of polymorphonuclear leucocytes is roughly proportional to the decrease in hæmoglobin. Leaving out the inflammatory periods, and allowing for the dilution, the absolute number of polymorphonuclears remains, roughly speaking, stationary throughout. The lymphocytes, taking all varieties together, come out practically the same in all cases. The mononuclears show a considerable increase in this case following the rule in typhoid fever. The eosinophiles occur only in very small numbers. It seems clear from these observations that during the course of this case there was considerable dilution of the blood.

On a Common Source of Diphtherial Infection and a Means of Dealing with it.—R. T. Hewlett and H. Montague Murray show by statistics that the Klebs-Loeffler bacillus and the pseudo-diphtheria bacillus exist in the throat in a large number of cases, especially in children, without producing any recognizable symptoms. Out of three hundred and eighty-five children under the age of fourteen, the former organism was found in fifteen per cent., while the latter was found in twenty-four per cent. Neglecting the latter, these figures show that one out of every seven children, or at least out of every seven sick children, is a possible source of diphtheria infection. The presence in a hospital ward of children under two years of age increases the risk of outbreaks of diphtheria. Kissing and other similar artificial demonstrations of childish affection should be discouraged. If after every meal, in the case of a breast-fed or bottle-fed infant, or night and morning in an older child, the mouth was swabbed or rinsed with some mild but efficient antiseptic, such as glycerin of boric acid and warm water, or a diluted solution of chinosol (1:1,000), many cases of diphtheria might be prevented.

Syphilitic Heredity.—S. W. MacIlwaine notes the case of a man aged forty-seven years, who incurred syphilitic infection probably between the ages of twenty and twenty-five. He was inefficiently treated. Within the last four years he has suffered from aortic and mitral regurgitation. He has two sons, aged eight and ten years, respectively. The elder within two years has had a nervous and mental break-down, while the younger has become epileptic. The writer believes that the cause of these disorders is syphilitic heredity, not hereditary syphilis. The distinction, if genuine, is of great practical importance as regards prognosis, treatment, and the attitude we bear toward the question of the risk of transmitting the evil effects of syphilis to succeeding generations.

Simple Continued Fever in South Africa.—F. J. W. Porter states that in the present campaign there has been a variety of continued fever which is not malarial and not enteric. The onset is rather sudden and the temperature may be from 102° to 104° at the end of the first day. There are generally much headache and considerable disturbance of the gastro-intestinal tract. There is more often constipation than diarrhœa. The duration is very variable, from two to seven or eight days, and there is very rapid convalescence.

Veld Sores.—J. G. Berne concludes that veld sores are not more common in the mounted men of the service than in the infantry. They are much commoner in the winter months—June to October. This sore is generally characterized by a purulent discharge. The lesion starts in two ways: (1) A blister; (2) by direct injury. The sores are always chronic in their course.

French Journals,

Malignant Tumor of the Eyelid.—M. Lagrange reports a melanotic sarcoma of the upper eyelid and of the bulbar conjunctiva. Histological examination showed that it was an angiosarcoma with interstitial hemorrhages and consecutive melanosis. In this case the pigment was of two origins—autochthonic and hæmatic.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, May 16, 1901.

Berliner klinische Wochenschrift, June 3, 1901.

The Hæmolytic Properties of Human Serum.—E. Neisser and H. Doering, in order to determine the degree of hæmolytic power possessed by human serum, made experiments which, briefly stated, consisted in adding it in varying amounts to rabbit's blood and observing the quantity required to destroy the erythrocytes. The results of their investigation lead them to believe that the human lysin thus experimented with has the same constitution as the animal immune and normal sera analyzed by Ehrlich and Morgenroth. The complement of this serum is invariably rendered inactive by heating for one-half hour to a temperature of 56° C. Rabbit serum and some horse sera contain a complement fitting the human middle body and reacting with it, and human serum contains at least two different middle bodies and two complements. The human blood used for these experiments was obtained from patients subjected to therapeutic venesection, and therefore suffering from the most varied diseases, yet the constitution and the quantitative solvent and combining powers of the lysin were constant. The possibility of finding differences in the reactions of the lysin, which shall be of help in the diagnosis of pathological conditions, is therefore but slight, while on the other hand any such change that might be discovered would have so much the greater significance. The serum of patients suffering from a blood disease, which would offer the best chance of detecting such an alteration of the normal conditions, was not examined.

Paralysis of the Large Intestine.—A. Hesse comments on the amount of attention given in text-books to incontinence of urine, while the therapy of the similar affection of the bowel is barely mentioned. A child aged six years, treated by the author, had for several years been suffering from both diurnal and nocturnal enuresis with frequent incontinence of fæces, and in consequence was a nuisance to itself and its surroundings. No reason could be found for suspecting a nerve lesion, while investigation of the stools pointed toward a chronic catarrh of the large and small intestines. This was treated along the usual lines by diet, astringents, and a course of mineral water, with the result that the alvine incontinence was entirely relieved and the bladder trouble much alleviated, though not cured. The causation of such a condition may depend on nerve lesions, local disease of the bladder or intestine, chronic enteritis, etc., and is to be diagnosed by the incontinence and relaxation of the sphincter. The treatment depends on the underlying condition and should be directed to this, while in addition the tone of the sphincter may be raised by electricity, and attention be paid to diet and regular evacuation of the bowel by means of enemata. Under careful management the condition is often much less refractory than is generally supposed, and an attempt at relief should always be made.

Münchener med. Wochenschrift, June 4, 1901.

What is To-Day the Mortality of Gall-Stone Operations?—H. Kehr first takes up the statistics of one hundred such operations which he has performed between April, 1900, and April, 1901. Out of this number sixteen fatalities are reported, but in his detailed analysis of the causes of death the author thinks that only one case can be justly attributed to the operation. The others were all hopeless from the start, with such complications as cholæmia, malignant disease of the bile passages, pancreas, or pylorus, etc., so that the cases are not typical. Of this number, however, ten deaths occurred among men and only six among women, which disparity is all the more remarkable since seventy-five per cent. of the whole number operated on were women. This, the author believes, is due to the fact that men make much poorer laparotomy subjects than women and stand the necessary manipulation in the abdominal cavity very badly. Adding these cases to all those he has previously treated the author has a list of five hundred and eighty-five gall-stone laparotomies done since 1890, and from these statistics he concludes that at the present time the mortality of such operations is very low provided the case reaches the surgeon before the pathological changes have gone too far, though it is high when carcinoma or suppurative cholangitis are present. If simultaneous operations are done on the stomach or intestines, the mortality is raised from five to twenty per cent., according as the trouble is malignant or not, while if the pancreas is also diseased the prognosis depends on whether this can be cured or not.

The Causes and Treatment of Menstrual Colic (Dysmenorrhœa).—A. Theilhaber says that while undoubtedly there are some forms of uterine disease that can produce painful menstruation, they are but few; prominent among these, however, are perimetritis and polypoid and submucous fibroids, which, acting like foreign bodies, are continually stimulating the uterus to contract in its efforts at their expulsion. None of the various hypotheses of other writers meet with the author's approval, and he discusses, only to reject, the theories that ascribe dysmenorrhœa to anteflexion, retroflexion, stenoses of the external and the internal os, endometritis, metritis, "ovarian" dysmenorrhœa, and the nasal dysmenorrhœa recently described by Fliess, which depends on the presence of so-called "genital spots" in the nasal mucosa. He himself believes the trouble is usually functional and depends on spastic contraction of the circular fibres forming the internal os. Such spasm is most frequent in neuropathic individuals, but even without any general nervous condition such causes as mental over-exertion, piano practice, over-indulgence in tea and coffee and alcohol, and masturbation may produce sufficient over-excitability of the uterine nerves to bring about the result. The palliative treatment comprises hot applications, prolonged hot sitz-baths, rest in bed, hot drinks, and antipyrin. Dilatation of the cervix brings temporary relief, but this is never permanent, and the most effectual measure is an operation devised by the author and consisting in the excision of small wedges from the substance of the cervix.

Spondylitis Typhosa.—A. Kühn gives in brief the histories of those cases of this complication of typhoid fever which have already been reported, and describes one of his own. In this case the symptoms of the spinal trouble began on the eighty-third day of illness, and the thirtieth day after the temperature had come down, and at first manifested themselves only as obscure pains in the left lumbar region. These gradually increased until, a month and a half later, the lumbar region was distinctly sensitive to pressure, and percussion of the spinous processes of the lower lumbar vertebræ caused severe pain. The patient was now obliged to lie stiff and motionless in bed owing to the pain caused by motion, but while keeping perfectly quiet he suffered no discomfort. The local symptoms gradually abated, though the lower spinous processes became somewhat prominent, and three and a quarter months after the beginning of the pain there was a distinct lumbar kyphosis. This persisted for some time but gradually became almost imperceptible again, and the patient, who at first had been almost unable to walk, regained complete function. The treatment consisted in the local application of ice and enforced rest flat on the back.

Deutsche medicinische Wochenschrift, June 6, 1901.

A Case of Foreign Body in the Gastric Cardia Diagnosticated by Radiography and Œsophagoscopy, and Cured by Gastrotomy.—G. Gottstein reports this case, which was that of a woman aged twenty-five years, who six months before coming under observation had swallowed a plate of artificial teeth which became detached from her gums while eating porridge. Since that time she had been somewhat troubled by a sense of a foreign body in the epigastrium together with some pain, but had not had actual dysphagia until about five months after the accident, when suddenly she became unable to keep down solid food, which was vomited again unchanged, while fluids passed without hindrance. She was three times examined with the œsophageal bougie by different surgeons, who were each time able to enter the cardia, while a Roentgen ray photograph showed a shadow in the epigastric region which, though suspicious, could not be regarded as very definite evidence. In view of the somewhat neurotic nature of the patient it was deemed inadvisable to operate solely on the ground of her subjective symptoms, which pointed rather toward neurasthenia; therefore, in order to obtain, if possible, further objective corroboration œsophagoscopy was tried, with the result that though the object itself could not be seen, an ulcer with eroded base and rounded edges came into view. Taking all the presumptive evidence together it was thought sufficient to justify operation, and a gastrotomy was done, with the result that the plate was successfully removed through the stomach from the perigastric tissue in which it had become embedded after perforation.

Strangulation of a Coil of Small Intestine through an Adherent Vermiform Appendix.—Hermes adds another to the anomalous manifestations of appendicular disease, which in this case caused the development of intestinal obstruction. The patient, a woman aged twenty-two years, was under observation in the hospital when she suddenly developed abdominal symptoms which were ascribed to perforative peritonitis due to a ruptured ulcer. On operation the stomach region was found free, however, but on investigating the right iliac fossa it was found that the tip of the appendix was adherent to the caput coli, and that through the ring thus formed a loop of gut had slipped and was tightly constricted. The appendix was extirpated in the usual way and complete recovery followed. It was evident that the appendix had been the seat of a chronic inflammation which had given rise to the long-standing gastric symptoms complained of, and since no adhesions existed between the strangulated loop and the constricting ring it is evident that the imprisonment of the small intestine had been a very acute affair.

International Medical Magazine, June, 1901.

On Oral Sepsis as a Modifying Factor in Gastric Affections.—George Herschell says that pyorrhœa alveolaris and the presence of septic stumps in the mouth may cause no disturbance if the motor power of the stomach is normal, the gastric juice destroying the larger proportion of the germs. The constant absorption of toxins may, however, set up neurasthenia, and stomach trouble may arise as a symptom of the neurasthenia, or secondarily. In some rare cases gastritis may be directly set up by the irritation of the septic material which has been swallowed. When the motility of the stomach is deficient either from myasthenia or as a consequence of pyloric obstruction, gastritis may be induced, or fermentation may be induced in the stagnating stomach contents and the case rendered much more serious and distressing. The physician should know how to treat pyorrhœa, especially in England, where dentists do not all recognize the affection nor know how to treat it.

Gastric Gas.—A. L. Benedict says that air may be introduced into the stomach by too rapid deglutition, by mechanical gastric respiration, by the inorganic and the organic production of carbon dioxide, but not by chemical gastric respiration. Gastric distention seems to be due to organic formation of gas, and mainly to fermentation of carbohydrates. Mild forms, with a sense of fulness and desire to belch gas, are common enough, and are well treated by the administration of hot carminative drinks, pounding on the back, change of posture, etc. Some severe cases with palpitation of the heart and symptoms of angina pectoris may be relieved by the passage of the tube and the escape of gas. When there is no organic disease, accumulations of gas are not dangerous, but in cases of cardiac degeneration it is logical to suppose that death might occur from gastric ballooning. Perforation of gastric ulcers are undoubtedly in many instances genuine instances of a weak gastric wall, due to increase of internal pressure, rather than of the extension of a degenerative process.

The Relations of Gastric Flatulency with Gastro-Intestinal Catarrhs and with Chronic Appendicitis; Treatment.—Boardman Reed gives a long list of causes of gaseous accumulations in the stomach. Catarrh of the appendix, with more or less occlusion of its opening, constantly breeds, and from time to time sends out into the cæcum, colonies of highly virulent bacilli. As a result the colon is kept constantly or intermittently affected, and even after appropriate measures have cured the catarrhal process in the bowel, there is reinfection from the persistent catarrh in the appendix, and this probably often involves the small intestine. The virulent bacteria escaping frequently from the chronically diseased appendix would greatly increase fermentation and putrefaction in the intestinal contents, and the gaseous accumulations there may at times find a vent in the upward direction through the stomach. Many patients who fail to get well of dyspeptic symptoms, including eructations, have appendices which are notably swollen and tender, and while they at times seem to improve, they relapse upon slight provocation and in spite of persistent care.

The Journal of Tropical Medicine, June 1, 1901.

A Case of Benign Tertian without Fever.—P. W. Bassett-Smith reports a case at Haslar, in which the special points of interest are: (1) The absence of fever; (2) the presence of well-marked tertian parasites in considerable numbers; (3) the absence of sporocysts in the peripheral blood; (4) the disappearance without the administration of quinine. The patient had been apparently cured in China and had taken quinine fairly constantly there and on the way home. The fever was cured, but the parasites were evidently not destroyed, but remained latent. The lesson learned is that systematic examination of the blood is necessary after malarial attacks, even when clinically there seems no evidence of active infection being present.

Relapsing Fever in Sumatra.—J. C. Graham reports the first case ever recorded in Sumatra. The blood was at first examined for malaria but the result was negative. Spirilla Obermeieri were found in abundance. The course of the fever was not influenced by quinine, but subsided to 35.6° C. on the sixth day to become normal the day after. He is now being treated by the iodide of potassium empirically, on the supposition that as this substance is said to arrest the virulence of the spirillum in inoculations, it may have an inhibitory action on the return of the fever.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

SOUTH AFRICAN HONORS—THE CIVIL SURGEONS—THE DINNER—GENERAL MEDICAL COUNCIL—THYROIDITIS IN TYPHOID FEVER—SUBDURAL HEMORRHAGE—DILATATION OF THE AURICLE—PLAGUE AT THE EPIDEMIOLOGICAL SOCIETY—OBITUARY.

London, June 7, 1901.

The King held an investiture on Monday, when the various recipients of South African honors, among them the surgeons whose names I sent you when gazetted, were introduced to the sovereign and received their several distinctions.

On Wednesday above two hundred civil surgeons who had been employed in South Africa during the war dined together. Sir W. MacCormac took the chair. Among the guests was the war minister, who said he was charged by Lord Roberts to express the high opinion he had of the services of the civil surgeons and his regret that he could not be present. He added that nothing would be wanting on the part of the government to induce the country to continue its patient endurance and bring the operations to a satisfactory issue.

The General Medical Council met on Tuesday and hopes to conclude its session within a week. This almost incredible hurry is not, however, any sign of repentance for its past waste of precious time and money. The good impulse arises from the desire of some members to be present at the centenary celebrations of the University of Glasgow. The council has appointed its president and treasurer delegates to that function. The president accordingly saw the necessity of shortening his address, and the members followed the example, so that business was transacted at an unprecedented rate.

Legislation is not more forward than last year—in fact, is rather more backward. The Lord Chancellor has promised to give the medical and dental companies bills consideration. Mr. Long has promised to look into the subject of death certification. The discipline bill is delayed by Sir R. Jebb's illness.

It is clear nothing will be done this year. The privy council has acted against the advice of the medical council in the matter of reciprocity with Italy, which turns out to be no reciprocity at all. This is not surprising, seeing that the vice-president lately said in the House of Commons that neither he nor the president had time to read the medical council's views. And yet this privy council is the court of appeal and has the charge of supervising the medical council.

The most interesting case of discipline is that of Dr. Irvine. He sent a letter but did not appear. He was ordered to come up to-morrow. So far the council has asserted its authority, notwithstanding the action of the education department, of which I apprised you last week.

At the Clinical Society on Friday Drs. R. Russell and R. Johnson related a case of convulsions from traumatic subdural hemorrhage on the sixth day after a fall down a flight of stone steps. The trephine was applied, and several drachms of dark blood were evacuated, after which no convulsions occurred and the patient recovered gradually. No explanation was offered of the late onset of the symptoms.

Drs. I. Owen and W. J. Fenton related a case of enormous dilatation of the left auricle of the heart—its capacity being thirty ounces, its greatest diameter six and one-quarter inches, excluding the appendix, which was itself dilated. The other cavities were dilated, though not to the same extent. The pericardium was adherent to the auricle posteriorly, and it was suggested that the dilatation originated from this fact. Paracentesis had been performed and the trocar had penetrated the auricle, pure blood resulting, and the operation was suspended. The patient seemed none the worse and survived three and one-half days, dying then of asphyxia, due to compression of the lungs. No change was produced in the auricle by the puncture. No change was found in the wall of the auricle except thinning.

Mr. R. J. Godlee then read notes of a case of acute suppuration of the thyroid gland complicating typhoid fever in a young woman aged twenty years. An incision was made and an abscess cavity evacuated. Bleeding was free but not alarming. A drainage tube was inserted and a cyanide dressing applied. The patient was more comfortable after the operation and made an uneventful recovery.

Mr. Godlee said thyroiditis occurred in connection with various infections. Of twenty-eight cases recorded he found there was suppuration in fifteen, and in six this point was not mentioned. It seemed common in typhoid. Cases were mentioned by Mr. Symond and Sir T. Barlow. The latter thought some of the cases were rather hemorrhages than inflammation; as in eruptive fevers, interstitial hemorrhages often arose in other parts—*e.g.*, the pancreas and suprarenal bodies.

"What is plague?" asked Dr. Klein, as the title of a paper at the May meeting of the Epidemiological Society. He proceeded to give a description of the bacteriological characteristics of the typical oriental disease, illustrating it with lantern slides. He stated the evidence in three suspicious cases which were brought to our ports some time ago—the three I mentioned to you at the time. Two of them gave positive evidence and the other negative. The bacilli, which he described, were very numerous in the pulmonary exudation and expectoration of pneumonic cases; in the septicæmic and hemorrhagic cases they swarmed in the blood, and hemorrhages took place through the mucous membranes of the respiratory, alimentary, and urinary organs; in the bubonic type they were generally limited to the spleen and lymphatic glands. In these, therefore, the possibility of infection was much smaller until the bursting of the glands, when he found the pus contained them, although it had been stated they disappeared on suppuration. The bacilli secrete a viscid substance, causing them to adhere in clumps, precluding emulsification and resembling at first agglutination. But the secretion dissolved in a saline solution, and then cultures could be emulsified. In this way he had obtained unequivocal agglutination in ten to fifteen minutes.

Mr. James Cantlie said marked types were easily recognized clinically—not so cases of pestis minor, such as seen in the East, preceding, accompanying, or following epidemics. He thought all enlarged glands with fever, not clearly venereal, should be regarded with suspicion.

Dr. McWeeney suggested that bacilli not giving full tests might acquire virulence later on.

Dr. Herbert Williams said that inguinal swelling was very common in Lascars, but the port authorities sent all cases with fever or suppuration and the pus to Dr. Klein for report.

Dr. P. T. Adams believed most cases were infected through a breach of surface or a catarrh of the air passages, and said in Bombay the mortality was highest in cold weather and during the monsoons, when the rains kept the people in crowded dwellings.

Dr. Farrar and Dr. Turner confirmed the low infectivity of the bubonic form, and the president (Dr. P. Manson) said it was now fully confirmed that the fleas of the rat would attack man in default of their natural hosts, just as the fleas of dogs or fowls would do.

The preliminary programme of the Congress on Tuberculosis has been distributed, together with invitations to attend and requests for subscriptions. It makes a brave show with the King as patron. There is a long list of vice-presidents and officers. The congress will be opened on July 22d and remain until the 26th. There are to be four sections: (1) State and municipal; (2) medical, including climatology and sanatoria; (3) pathological, including bacteriology; (4) veterinary (tuberculosis in animals). There will also be arranged a museum of pathology, bacteriology, and public health. The foreign governments are invited to send representatives, who will be honorary members of the congress.

Dr. Bond's death yesterday startled those who were not aware of his illness, by its tragic character. He was the medical jurist consulted by the criminal investigation department, and his name you will remember as associated with all the sensational criminal trials for more than twenty years past. He had become the victim of melancholia and was lately confined to bed. Yesterday morning he threw himself from the window of his house, which was opposite the Westminster Hospital, from the staff of which he retired about two years ago, and into which he was now carried. Thomas Bond was M.B., B.S. of the London University, where he took the gold medal in surgery in 1866. The same year he took the F.R.C.S. Eng. He was elected on the surgical staff of the Westminster Hospital in the early seventies and served it faithfully for some twenty-six years. He lectured in the school on both surgery and forensic medicine. He was also consulting surgeon to the Great Eastern and the Great Western railways, and had naturally a large practice in medico-legal cases. He wrote the article on "Railway Injuries" in "Heath's Dictionary of Surgery," and contributed various papers to the journals.

Dr. James A. Myrtle, of Harrogate, died on Sunday in his forty-first year, of acute laryngitis. He presided at a public meeting two evenings before, and then seemed well. He was the son of Dr. A. S. Myrtle, so long associated with Harrogate and its waters. He took great interest in public matters, for two years was mayor of the town, and to his initiative or advocacy many of the recent improvements at that important health resort are due. He was a magistrate for the borough, surgeon-lieutenant of the Yorkshire Hussars, and fond of athletics and sports. He was co-edi-

tor of his father's work on the Harrogate mineral waters and contributed a number of papers to the journals on balneological subjects. All the institutions of the town were represented at his funeral—a military one—on Wednesday, and his early death is deeply regretted.

Dr. Griffith Hall died on the 28th ult. He was consulting surgeon of Swansea Hospital, was a magistrate, and the oldest practitioner in the town, being eighty-seven years of age.

Dr. Andrew Davies, another Welsh magistrate, died on the 25th ult., aged seventy-seven years. He was formerly also surgeon to Swansea Hospital, but retired from practice in 1887.

Another Welsh doctor, who once was a magistrate, died as long ago as March 30th, aged seventy-three years: that was Dr. Llewellyn Williams, who supervised the exhumation of the body of Mrs. Dante Rossetti in order to take up the manuscript her husband buried with her, but seven years afterward wished to recover and publish.

OUR PARIS LETTER.

(From our Special Correspondent.)

VICHY—THE USE OF DRUGS IN THE FRENCH HOSPITALS FROM THE PHYSICIAN'S POINT OF VIEW—FRENCH PHYSICIANS' VISIT TO THE GERMAN UNIVERSITIES—DR. LAVERAN MADE A MEMBER OF THE INSTITUTE—NEW DRUG USED AGAINST CANCER—LEPROSY ASYLUM IN FRANCE—THE EARLY USE OF ANTIDIPHTHERITIC SERUM.

PARIS, May 30, 1901.

It is generally thought that from a purely financial point of view German watering-places have proved to be much more successful than the French places of the same nature. This may apply to a certain number, like Nauheim, Marienbad, Carlsbad, and others, but it would be difficult to find an establishment the success of which has been more lasting and progressive than that of Vichy. The waters of Vichy belong to the state, but they are rented to a company, which has recently renewed its lease for thirty years, with the understanding that ten millions of francs shall be expended in improvements. The shares of this company were put on the market at 500 francs, and then were divided into four parts, and each share now is worth 8,000 francs. The profits are due not so much to the large quantity of water drunk at the sources, as to the immense exportation of Vichy water to foreign lands. There is no cure tax at Vichy as at most watering-places in Germany, so one is obliged to use the statistics furnished by the railroad, and from them one can estimate the number of patients seen yearly at Vichy at about 45,000. In 1900 14,700,000 bottles of Vichy-État were sent out, whereas in 1853 only half a million were exported.

In the last letter published in the MEDICAL RECORD, mention was made of the fact that the expense entailed by drugs in the hospitals had increased noticeably during the last fifteen years. Dr. Lermoyez, a well-known specialist for the throat and nose, as well as a physician of the hospitals, has taken up this question and has written a sarcastic letter on the subject. As Dr. Napias' place as general director of the Public Assistance has been assumed for the time being by the "very distinguished general secretary of the Assistance Publique," Dr. Lermoyez begins his letter by mentioning his efforts to produce certain changes in the hospitals. It was established by law that the physician's visit should be made early in the morning, at or before eight o'clock. Nowadays physicians begin their rounds at nine o'clock, but some of them are very irregular. To give an example of how differently the chiefs of service may act, at one of the principal hospitals there is one physician who arrives almost exactly on time in his service at nine o'clock every day, and this he has been doing for years; he moreover takes only two months' vacation every year at the same date; whereas one of his colleagues comes at very irregular hours and examines only a few of the patients in his wards, leaving to his chef de clinique and interne the task of examining and reporting on the different cases. Dr. Lermoyez remarks that it would seem that physicians were causing great expenditure, and he mentions incidentally that the 125 francs a month they receive are already a source of ruin. Codeine costs very dear, being sold at 700 francs the kilo, and the circular sent out by the general secretary recommends the use of morphine, which would cost three times less. As for pilocarpine, it costs 3,000 francs the kilo, and whenever Dr. Lermoyez orders it in his service the pharmacist appears on the scene, to explain that the extract would be preferable to the alkaloid. Still it should be remembered that fifteen injections of one centigram of pilocarpine would only cost 45 centimes, or nine cents. Digitalin, which was introduced by Potain in France, would seem to be the most expensive, 30,000 francs a kilo being its price. Dr. Lermoyez says he seems to hear Dr. Potain's voice pleading its use before a dead and buried board of trustees of the Assistance Publique, and telling them that since only one milligram was needed for each case of mitral regurgitation, it did not seem too much to spend two cents on three cases of asystole.

Not only are French physicians and students going more and more to Germany to visit the different universities, but trips are being made by forty or fifty medical men together, and the *Presse Médicale* has just been publishing the description of a trip of this sort as furnished by one of the members of the excursion. They visited Lille and Liège, and then went on to Cologne, where the Burger Hospital was visited. This hospital contains the service of the celebrated Professor Bardenhauer, which has seven hundred beds. The most striking points were the great numbers of cases of surgical tuberculosis, and the extreme care that is taken of all cases of fractures and dislocations. The existence of so many cases of tuberculosis of the bones is to be found also in other German towns according to Dr. Jayle, and as for the organization that is shown in the treatment of fractures in most surgical clinics in Germany, one is struck by the abundance of appliances and apparatus, and the part given to massage, a special assistant being appointed for this. Bonn was next visited. The Institute of Chemistry and that of Pathology were found very well arranged, but, on the other hand, the Institute of Anatomy was poorly equipped. The dissecting-tables were small, and were used alternately for dissection in winter and histological work in summer. The hospital was visited afterward, and it was explained that there were three categories of patients. Patients of the third class pay 2½ marks a day, and are lodged in wards containing fifteen to twenty beds. There are also bedrooms with two beds, where the patients pay 5.30 marks a day, and lastly rooms with only one bed for patients of the first category, paying 8 marks.

Heidelberg was found to be much more interesting, and the French physicians were received with a great deal of cordiality by Czerny, Erb, Kraepelin, Kehrer, Kossel, and Leber. The evening was spent at a beer saloon, and Czerny welcomed the French physicians in a speech which was very much applauded. The next day Erb's service was shown, and what impressed the narrator of the visit was the appearance of comfort and home life shown in the patients' hall. Czerny's service was very well equipped, there being laboratories for histology, bacteriology, radiography, and even a room for vivisection. Kehrer's service was not very extensive, as there was rarely more than one obstetrical case a day. What excited the most interest was the way in which the clinics were managed. Several patients were brought in and one of them was operated on, while the next was awaiting his turn. An examination of a patient was afterward carried out by one of the students, and then the professor took the case up and completed the questions put by the student. Each one of the latter was supposed to carry out this examination six or eight times every six months, which would be hardly enough to give him any clinical instruction if it were not for the instruction given by the privat-docent.

The highest honor that a physician can attain to in France is to be made a member of the Institute, and a recent election was held to choose a successor to Professor Potain. The votes had to be cast three times before Dr. Laveran was chosen by forty votes, against twenty-six given to Professor Richet. Dr. Laveran is a military surgeon, the author of an excellent work on general medicine, and well known for his researches on malaria.

There has been some talk of founding a sanatorium for lepers at Ronceaux in the department of Vosges, but the inhabitants of this part of the country are not at all desirous of having any such undertaking carried out. The subject was discussed at a recent meeting of the Academy of Medicine, and the following points were insisted on: There are several cases of leprosy at the St. Louis Hospital and no cases of contagion have been noticed so far. It would be well to establish a sanatorium in places where cases of leprosy already exist, for instance on the Riviera where several cases of leprosy have been found.

Still another method of treating cancer, similar to that by methylene blue, has been brought before the medical public recently. It consists in the use of Flemming's solution of osmic acid, applied locally or injected into the cancerous tissue. According to the results furnished by Dr. Hérard and described at a meeting of the Society of Therapeutics, the drug causes no symptoms of poisoning, the urine not being modified to any appreciable extent. The results obtained so far are a manifest diminution of the pain, due most likely to an antineuralgic action, and a marked diminution of the secretions and fetor.

The president of the counsel of ministers, who is also secretary of the interior, M. Waldeck-Rousseau, has sent a letter to the physicians who report epidemics, in which he speaks of the advisability of using the anti-diphtheritic serum. He remarked he had seen noticeable differences

in the statistics from different parts of the country; in some places almost all the patients inoculated recovered, while in others more than half of the cases ended fatally. This difference would seem to be due to the fact that some physicians do not care to use serum which seems in any way tainted, when there is, for instance, a slight deposit. It should be remembered that this does not indicate an impure serum, and that every hour is of importance. Statistics show that when the injection is made the first day the false membranes appear, the death rate is at the most two per cent.; the second day it is six per cent.; it goes up to thirty per cent. when the injection is only made the third day, to fifty or sixty per cent. when it is performed the fourth. M. Waldeck-Rousseau's letter ends with an appeal to the sanitary inspectors to see that such requirements be carried out, *i.e.*, the early use of the antitoxic serum. Dr. Chantemesse, who has charge of the diphtheria service at the isolation hospital for contagious diseases, made some remarks on the same subject at a recent meeting of the Medical Society of the Hospitals. A great number of children, fifty-six out of seventy, die the day they are admitted to the hospital, and this is due to the antitoxin not being injected soon enough. It is dangerous to wait until a bacteriological or clinical examination has demonstrated the existence of diphtheria. Injections have generally proved to be so innocuous that it would be foolish to wait for fear an injection might produce some pathological symptoms.

LETTER FROM CONSTANTINOPLE.

(From our Special Correspondent.)

CONSTANTINOPLE, May 13, 1901.

AGAIN an alleged case of plague, and again Turkey is in the agony of quarantine, and Constantinople itself, with its own neighboring ports of the Marmora and Black Sea.

On May 1st a case of plague was officially reported as having occurred in Galata, in a macaroni establishment. The man, a native porter (or *hamal*), when taken ill was removed to a small *locanda*, or boarding-house, a few yards higher up the same street, on the opposite side. The next thing heard was that the man had developed plague. The macaroni establishment was closed. The *locanda* was placed in quarantine with all its occupants, stated to be about thirty-seven in number, and who shortly afterward were carried off to the quarantine station at Anatolia-Kavak on the upper Bosporus. Immediately Greece, Bulgaria, and Roumania imposed a quarantine of ten to eleven days against Turkey; Russia, a milder one of medical inspection, and Turkey, as already noticed, put herself in quarantine against herself.

Again (May 6th), on account of a case of plague in Egypt, arrivals from Alexandria are submitted to a quarantine of observation of forty-eight hours, with disinfection at one of the lazarettos of the empire. Also a suspected case is reported at Bagdad, and the inspector of the sanitary administration at Bagdad is instructed, by date of May 8th, "that tents are to be established for the caravans going toward the Euphrates, Kerhela, and other countries, and a quarantine of five days, with chemical disinfection and daily exposure to the sun of the effects of the travellers. All vessels leaving Bagdad for the south will undergo quarantine at Gararah, and patrols will prevent any one escaping from quarantine. Municipal and military doctors will be sent to the villages adjoining Bagdad, and in Bagdad itself medical men will visit all parts of the city and will immediately announce any case of plague. Finally the conveyance of Shiite dead bodies to the holy places is forbidden until further notice."

Then, "the ports of Constanza and Mangalia are closed to the same arrivals from Constantinople. Mails from Turkey will be received at Verciarova, the frontier, and the bags disinfected. Pattern parcels from Constantinople are also prohibited."

On May 10th is the following official notice: "Seeing that ten days have elapsed since the declaration of a case of plague in Constantinople, and the public health is declared perfect, the measures decreed on May 2d against arrivals and departures to and from Constantinople are suppressed, and clean bills of health are delivered."

Next—Egypt imposed a medical visit and disinfection on arrivals from Constantinople.

The strict measures taken at Bagdad have probably more reference to the great Shiite pilgrimage as preventive than to the actual presence of the disease, and the conveyance of the dead to the holy shrine is properly forbidden at that season.

This is the second time within a few months that the commerce of nations has been disturbed, the mail service dislocated, and passengers and tourists subjected to personal discomfort and loss on account of a single alleged case of plague. It might be supposed that all these demonstrations would strike terror in a population like that of Constantinople. But no! No one seems to believe in the necessity of such extreme measures as have been taken either by the other states or by Turkey against herself; and the inconsequent character and incidence of the regulations issued are pointed out. The Bagdad regulations are necessary for the reasons stated; but in Egypt, where plague is now more or less permanently located, and where a case every now and then crops up and is easily controlled, it is somewhat different. In Constantinople and Alexandria occurred, coincidently, single cases of plague. Each place imposed a quarantine against its neighbor, in this respect imitating the practice of former days, just as if no means of organized isolation existed in either place. Then, again, while some neighboring Turkish ports and places on the Marmora and Black Sea coasts were in quarantine against Constantinople, the daily passenger traffic from Galata—where the case occurred—was in free communication with the Asiatic side of the Bosporus and the Prince's Islands of the Marmora, when thousands pass daily to and fro. All very inconsequent, though likely to be repeated in the event of another scare from a true or alleged case of plague or cholera. The two cases of plague that have occurred—the one at Beicos noticed on a previous occasion, and this one in Galata—were stated to be confirmed by bacteriological examination, and were treated by serum injections, but whether the examination preceded or followed the injections is not stated. Now quarantine has been taken off or modified all round. The mail services have been resumed and the ordinary business relations are being restored.

The case of hydrophobia mentioned in a former communication has since been under discussion by the Imperial Society of Medicine. Professor Remlinger, of the Anti-rabic Institute, enunciated certain views as to the special form of rabies, *i.e.*, the paralytic form, found in Constantinople. An animated discussion ensued. A member asked the professor how often he had observed at the Anti-rabic Institute that the patient had shown symptoms of hydrophobia after the bite, because in Constantinople dog-bites for the most part were not followed by rabies, compared with those in Europe. Dr. Remlinger replied that he "could not answer the question, as most often the animals were not submitted to examination. The veterinaries very often make their diagnosis of rabies from the foreign bodies found in the stomachs of the animals, which is irrational, as it is not uncommon to observe that dogs stung by wasps in summer swallow foreign bodies. In Constantinople it was true that cases of rabies are not so numerous as in Europe, considering that the street dogs of Constantinople are more subject to paralytic rabies than to violent rabies (*rage furieuse*)."

The fact certainly is that rabies in any form is not common among the pariah dogs of Turkey. Your correspondent has lived many years in Constantinople, yet has never seen a case of hydrophobia in men bitten by dogs, nor a well authenticated case of rabies in street dogs. It would then appear that the opinion of Professor Remlinger is not founded on such a number of cases as to justify its unqualified acceptance.

ASEPSIS AND AMBULANCE SURGEONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the MEDICAL RECORD of June 15th I read an article under the above title, which I have taken the liberty of using in my reply, as it is pre-eminently a correct statement of facts, whereas the gist of the writer's letter showed him to be absolutely ignorant of his subject.

I have been an ambulance surgeon myself, while connected with the Hudson Street Hospital, and in the performance of my duties have come in contact with numerous surgeons from other institutions, and I think I am in a position to judge of the work done daily by our ambulances, as I see the result constantly in my clinic.

I do not claim that a surgeon on the back of his ambulance is surgically clean, but that he thrusts his "dirty finger" into every wound, "especially if it involve brain, joint, or peritoneum," I characterize as untrue and made necessarily by a man not well versed in the subject he is trying to discuss.

Dr. Ellis says that a physician is called in first who applies an aseptic dressing at once, before the officer summons the ambulance. That statement shows how little the doctor knows of the rules regulating this service, as any one will bear me out who has attended to many ambulance calls. The majority of ambulance surgeons are graduate physicians and should be treated as such, and not as mere novices; they are much maligned by the daily press, as they are considered perfectly legitimate prey by the reporters. They make mistakes, of course, but when you consider the number of calls per annum in this city and then the very few mistakes, the average is really remarkable.

CLINTON H. CATHERWOOD, M.D.

NEW YORK.

Society Reports.

AMERICAN ACADEMY OF MEDICINE.

Twenty-sixth Annual Meeting, Held in the Hotel Aberdeen, St. Paul, Minn., June 1 and 3, 1901.

THE meeting was opened by the president, Dr. S. D. Risley, of Philadelphia.

The First-Year Medical Curriculum.—DR. THOMAS D. DAVIS, of Pittsburg, Pa., presented this paper. He said there had been great changes in the curriculum of the academical departments of all our institutions of learning—changes, not advances. He did not admit that many of the changes had been improvements in education. It would appear that the courses in arts and sciences had been arranged mainly to give a short cut into the profession, rather than to broaden and deepen the foundations of true mental development. It was his conviction that no plan surpassed, for true professional-education foundation, the old severe classical course, particularly valuable in developing the judgment and reason and forming the habits of application and mental concentration. Anything that could not show its advantages in dollars and cents had been placed in the background. He emphasized the importance of the subjects taught in the last two years of a college course, and believed that the first-year course of a medical school should approach the last-year course in a college. A four-year medical course was of itself an advancement in medical education. An entire rearrangement of the curriculum in our medical schools was necessary to correspond to the four years required. Rhetoric could be taught with advantage. Botany should be taught, to give a more correct foundation for the vegetable materia medica. Logic, if not taught before, should be taught in our medical schools. In no way, it was stated, could the practiee of medicine be improved more rapidly and thoroughly than by training men to think, judge, and decide logically. Psychology or mental philosophy was mentioned as of greater importance than all. The intimate mysterious relation of the mind to the body had been recognized, but the laws governing the mind and the many phenomena that had been observed and classified were, to a great extent, unknown to medical men. The physician who failed to recognize and use mental influence lost a mighty power, yet our medical schools taught none of the laws of this influence. In the opinion of the author, a medical college offering a course for the first nine months, which would embrace rhetoric, botany, logic, and psychology, biology, osteology, and general chemistry, would, at the end of its four years' course of nine months each, turn out far better equipped medical men than were to be found at graduation now. Under the present conditions a college graduate with three years in a medical school would be better posted in medicine and better prepared to practise it than a common-school graduate could possibly be after four years in the same medical school.

DR. CONNOR, of Detroit, believed that colleges of all kinds were committing a grievous wrong to their students in not having them taught to write so clearly and forcibly that they could be understood, as well as in not teaching them how to talk when upon their feet. Without this training they were handicapped. If necessary, this instruction should be joined with the study of anatomy and chemistry. Manual training, so that the students' fingers might be able to follow out their perceptions, was also advocated; as was also "a little bit of business training," which would make the physician more prosperous, and more reputable in the minds of those in business circles. A number of physicians were wrecked because they lacked business training.

DR. VAUGHAN thought it a mistake that students were not more frequently compelled to write theses, and that the abolition of the requirement was a backward step. Before a man studied medicine he should know mathematics, including plain trigonometry. Also, the man who would get the best out of medicine must have a reading knowledge of French and German. He should have some knowledge of both Latin and Greek. The fact that a man had an A.B. degree might mean much or almost absolutely nothing. The speaker thought it time that those interested in medical education in this country should force the literary school to give courses that properly led to medicine. He expressed himself in sympathy with the law enacted by the New York legislature compelling every student to stay four years in a medical school, no matter what degree he might have.

DR. GOLDSPOHN, of Chicago, heartily indorsed Dr. Vaughan's sentiments in regard to a knowledge of French and German. While not judging England and all she represented in science, yet more original productions, more real contributions pertaining to pathological anatomy, came from Italy and Switzerland, the smallest European governments, than we had from England herself in the last five or ten years. He felt that there was no possibility of a man keeping abreast with what the world afforded unless he were a thorough student of German and French, from them getting the substance of what the rest of the world produced. A deficiency in the medical curriculum of to-day was the failure to appreciate the power of mind over matter, the want of a proper understanding of this psychological part of man. The amount of instruction in histology was grossly defective. He felt that a good thorough college course and then a four years' medical course were likely to do the most good.

DR. JACKSON, of Denver, thought that the study of logic and psychology, as now carried on, furnished a very poor outfit, or a very insufficient guarantee of a logical mind or an ability to apply psychological principles to general facts. In illustration, he stated that a baseball or billiard player learned to do a certain thing with perfect accuracy, promptness, and ease, and yet knew nothing, perhaps, of the names, or forms of classification, or arrangement of the muscles by which he did it, and still less of the nerve paths by which he accomplished his purposes.

DR. L. DUNCAN BULKLEY maintained that the crowning evil of medicine, the advertising drug business, was due to faulty education in our medical schools. Another fault lay in too great a crowding from minutiæ. He emphatically approved of the suggestion that students be required to write a thesis at the end of each year. He had seen too often, in young men coming up for hospital examinations, a want of concentration of thought and of logic.

Is the Demand for Reciprocity Based upon Fact or Fancy?—DR. CHARLES MCINTIRE, of Easton, in this paper gave the results of the examination of reports of the various State boards of medical examiners for 1900, in order to form an estimate of the comparative number of physicians who sought to move from one State to another. The figures quoted in the paper gave the entire number examined, the number failing, and, of those failing, the number who were not graduates of the last class. A tabulated statement showed that out of five hundred and eleven individuals, two hundred and ninety-two could have had an opportunity of taking a State examination elsewhere. A considerable number failed, and were coming up for a second time, only to fail again. It would be far from the truth to infer that of the larger number who were sustained in their examinations, the same proportion of older men

presented themselves; at the same time, many such were included in those who received a license, and it would not be an overstatement to assume that the number of those who passed the examinations, who would have had the privilege of reciprocity extended to them, fully offset the number who failed in the examinations, who had never made the effort to practise elsewhere. If so, there were at least two hundred and ninety-two out of the total number examined who would have been able to avail themselves of the privilege of reciprocity, or about seven and a half per cent.

The Desirability of Reciprocity in Medical Licensure.—A paper with this title by Dr. J. N. Hall, of Denver, was presented. An experience of six years on the Colorado State board of medical examiners demonstrated that many physicians of excellent repute sought a residence in that State because of illness, either personal or otherwise. Though such men were fitted to practise medicine, they were rusty on the details of the foundation studies. Reciprocity between States having stringent requirements would be of the utmost benefit to men of this type. Reciprocity, however, should not be established, except among those States where requirements were essentially equivalent.

Reciprocity in Medical Licensure from the Standpoint of a Physician who Changes his Residence.—Dr. Edward Jackson, of Denver, in this contribution said that about one in every four or five physicians changed his field of practice from one State to another at some time during his professional career. In making such a change the difficulty was not with the practical branches, but in passing the examination in what might be regarded as the preliminary studies—chemistry, anatomy, etc. The physician who removed across State lines could not justly be expected to keep better posted in those branches than the most of those who did not move. The acceptance of the certificate of another State board, as evidence of a proper acquaintance with such preliminary studies, would remove the chief hardship. The main obstacle to this was the fear of lowering the standard. But the "standard" in many States was already so high as to favor evasion and special legislation, letting in all sorts of irregular practitioners, and to threaten the permanence of laws regulating medical practice.

Away with Reciprocity.—Dr. Charles McIntire in this paper stated that reciprocity was an ignis fatuus, which would lead us far astray. It was well to remember that the States which had medical-practice acts at all worthy of the name might be divided into two classes—those which accepted certain diplomas as the evidence of fitness, and those which required an examination. In both instances the test was an educational one. The first class had no personal interest in this question, since they did not inquire into the personal knowledge of the applicant. In the very nature of the thought, there was concession in reciprocity which precluded the idea of strict equality. If we sought reciprocity, we must seek to secure an agreement between the various boards, for each to accept without question the licenses issued by each other. Physicians already possessing the legal right to practise in one State should have privileges, in removing to another State, not accorded to those who had not as yet been licensed to practise. It might be said that the man distinguished enough to be called eight hundred or one thousand miles to occupy a professor's chair might be admitted upon his reputation. Unfortunately, were this done in one case, there would be the danger of pronouncing it reputation, but spelling it "influence." Whatever privilege was given to the older man, while a favor to him, must be fair to all concerned.

Some of the Ethical and Sociological Relations of the Physician to the Community.—Address of the president, Dr. S. D. Risley, of Philadelphia. Dr. Risley in his address showed that a most striking characteristic of the medical man was a sense of obligation to the community; that this ethical attitude found expression, not only in the daily routine of his laborious professional service, but in a pronounced educational influence on all those lines which pertained to the healthfulness of the people and their socio-medical welfare; that this influence was signally exerted in the investigations and control of the relation which our defective classes sustained to the social body. Almost suddenly the student of social evolution had come to realize that through the altruistic spirit of our civilization a rapidly increasing percentage of degenerates had grown up in our midst, a fact which presented a serious and most complex problem for solution by the new century. Two suggestions were made for its arrest: first, the legalization of means to prevent propagation of defectives, by asexualization; and, second, by a wider education of the community regarding the importance of selection in the marriage contract and its control by the State. To solve the problem wisely and humanely would require the best efforts of the churchman and the physician and the statesman.

Abuses of Institutionalism.—Dr. Eugene G. Carpenter, of Columbus, Ohio, read a paper with this title, in which he said that institutionalism was an outgrowth of organization and the result of routinism. Routinism developed perfunctoryism, which in turn led to automatism, differing little from the mechanical. That which was mechanical moved in fixed lines and was consequently opposed to progress.

The Advantages of Civil-Service Principles in the Conduct of State Hospitals for the Insane.—Dr. Gershom H. Hill, of Independence, Iowa, and superintendent of the Iowa State Hospital for the Insane, in this paper treated of the benefits resulting from having a board of three in control of the State institutions of Iowa, in practice for two and a half years. It was shown that the system was free from political influence. In the hospital under Dr. Hill's supervision, the personal element in the treatment of patients was preserved, and there was no interference with individually approved ways of treating patients. The business of the State institutions was transacted on the same methods as those employed by the United States government in buying supplies or by the up-to-date business man.

The Need of National Co-operation in the Establishment of Sanatoria for Tuberculosis.—Dr. A. Mansfield Holmes, of Denver, recited among the advantages of sanatoria that they increased the chances of recovery, afforded an opportunity for rigid sanitary regulations among patients, and furnished a means of educating the consumptive and the public in the use of the best means of resisting infection. He divided sanatoria into three classes: for patients of limited means, for those of moderate means, and for the well-to-do. Regarding the location of sanatoria, he said, there should be for the incurable cases sanatoria located near large centres of population regardless of climatic conditions; but for the incipient cases the most favorable climatic conditions should be chosen for the location of the sanatoria.

Evils in Some Asylums, Hospitals, Infirmaries, and Training-Schools for Nurses.—Dr. Albert Goldspohn, of Chicago, spoke on this subject, contending that many of these institutions did not yield their intended degree of usefulness because of exclusively lay management and because of political influence in the appointment of the officers of such institutions. He advocated giving the State board of health the additional duties, powers, and emoluments of a medical

civil-service board, which should select and determine the fitness of all superindendents, matrons, and other officials of hospitals and asylums, present candidates for medical appointments, and inspect the institutions at least once a year.

Hospitals and Sanatoria Founded, Owned, and Controlled by the Medical Profession.—Dr. H. Bert Ellis, of Los Angeles, described a hospital owned and controlled by a corporation of physicians known as the California Hospital Company. The first building erected for the hospital was soon found to be inadequate and was added to. The patients selected any reputable physician they might wish and paid him for his services. Connected with the hospital was a training-school for nurses. The absolute management of the hospital was vested in a board of nine directors, elected annually from among the stockholders.

The Relation of the Clinical Laboratory to its Hospital.—Dr. Henry W. Cattell, of Philadelphia, presented a paper under this title, in which he assumed that the time had gone by when it was necessary to argue for the existence of a clinical laboratory in connection with a hospital. The questions to be considered in the internal administration of a hospital were the relations of the clinical laboratory to the board of managers, the medical and surgical staff, the chief resident physician, the resident physicians, the superintendent, the nurses, the out-patient department, etc.

Dr. W. W. Keen, of Philadelphia, said he was glad indeed that he had heard the paper of Dr. Cattell. He was less interested, perhaps, in the clinical laboratory from the administrative point of view than from the scientific and surgical. He emphasized the statement that at the present time every hospital, small or large, should have a clinical laboratory.

Necessity for Revising Medical Fees.—Dr. P. Maxwell Foshay, of Cleveland, read this paper. He said that the custom of charging a fixed sum for each visit was a relic of antiquity and illogical. He argued that the general practitioner should proportion his charge in each case to the value of the service rendered and to the ability of his patient to pay. There was, however, a need of a "fee-bill" to establish a standard to which the physician could appeal when dealing with patients. It would also be of definite service in court on the occasion of a suit to recover the amount of a bill.

Refraction.—Dr. James A. Spalding, of Portland, Me., related a personal experience of a man suffering from a sudden loss of vision, who consulted first an optician and then an oculist for aid. His experience demonstrated the inefficiency of the former and the competence of the latter. Dr. Spalding suggested the advisability of physicians instructing the public through the secular press regarding all sort of ailments, thereby preventing them from yielding to the beguilements of charlatans. Physicians ought also to be careful in referring their patients only to those who had a proper knowledge of disease.

Dr. Tuckerman, of Cleveland, and Dr. Risley, of Philadelphia, referred to cases in which grievous damage had been done through the failure of physicians to refer their patients to an oculist rather than to the advertising optician.

Officers.—The annual election resulted in the choice of the following: *President*, Dr. V. C. Vaughan, of Ann Arbor; *First Vice-President*, Dr. James L. Taylor, of Wheelersburg, Ohio; *Second Vice-President*, Dr. W. A. N. Dorland, of Philadelphia; *Third Vice-President*, Dr. H. P. Ritchie, of St. Paul; *Fourth Vice-President*, Dr. H. Bert Ellis, of Los Angeles, Cal.; *Secretary and Treasurer*, Dr. Charles McIntire, of Easton, Pa.; *Assistant Secretary*, Dr. A. R. Craig, of Columbia, Pa.

AMERICAN PEDIATRIC SOCIETY.

Thirteenth Annual Meeting, Held at Niagara Falls, N. Y., May 27, 28, and 29, 1901.

First Day—Monday, May 27th.

Summer Diarrhœa. — The session opened Monday morning with an address by the president, William D. Booker, of Baltimore, on the subject of summer diarrhœa. He traced the literature in the older books, chiefly since the middle of the eighteenth century. From that time there had been an epidemic disease in the summer months, occurring in children under two years of age, characterized by vomiting and diarrhœa. It was not recognized in Europe, nor known to exist among the early settlers in this country. It had pushed back from the Atlantic coast, as the people had settled farther back. Benjamin Rush described it here as cholera infantum in 1777, but Europe did not appreciate it until fifty years later. Its virulence here accounts for its recognition early. In 1650 London recognized that children died in summer from heat and exhaustion. By 1750 diarrhœa was described as of fourteen kinds. Though often due to fatty food, it was not often seen in Germany. In 1818 cases were described as sporadic and due to eruption of the teeth. In 1840 appeared a work, giving much space to the diarrhœa of children, and describing cholera infantum as peculiar to the United States.

Green Scours.—Cheyne was the first Englishman to write properly of this disease, which he termed "green scours." He did not inculpate atmospheric changes as etiological factors. Moisture, sudden cold, and improper food were early recognized as causes. The last half of the century made little gain over the first half. Rush gave the first concise etiology and pathology. In 1803 one hundred cases were reported as treated with alkalies, with only one death. As long ago as 1823 Howell declared that "had only a portion of the talents wasted on fever been spent on the treatment of cholera infantum, tens of thousands of lives had been saved." He treated by calomel. The early writers all noted heat as a factor, but not as a cause. A miasm was suspected, because atmospheric changes seemed to influence its occurrence. The theories of exhausted nervous system and of deranged action of the skin were put forward. The pathology received little attention until Jackson demonstrated the inflammatory condition of the intestines. Now we knew that the causes related chiefly to bacteriology and the main reliance of treatment was in dietetics.

A Case of General Arteriosclerosis in a Boy Aged Ten Years was described by Dr. Allen Baines, of Toronto. Only seven similar cases had been reported. The boy had pipestem-like arteries throughout the body. Syphilis, the common cause, was eliminated here; nor was there rheumatism. He was anæmic, dull, and had no intelligence. There were almost uncontrollable hemorrhages from the mouth and nose. An ulcerative stomatitis prevailed, and was so bad as to suggest noma. The urine contained eight per cent. of albumin, and at autopsy the kidneys were found to have the parenchyma largely replaced by fibrous tissue. The heart was large; even the coronary arteries were fibrous, the aorta was atheromatous, and all arteries were standing open. The doctor also narrated a case of pelvic metastasis in a girl of sixteen years who had mumps and uterine hemorrhage worse than usually seen in abortion.

Pernicious Anæmia in Infancy.—Dr. T. M. Rotch, of Boston, reported in detail a case in a girl aged nine months. While anæmias were often examined in adults, the data as to infants were very insufficient. While the disease was usually secondary to syphilis or malaria, neither existed here. Primary pernicious

anæmia had been reported in twenty-five cases only. This was the third youngest on record. The cause, he stated, was not known, and the term idiopathic should be applied only to those in which no probable cause could be found. The child was normal at birth and breast-fed until four months old; it was then given milk of the strength 3.50–7 : 1, increased to 4–7 : 2. When ten months old, pallor and puffiness were noted, also a faint precordial murmur. There was no rickets or scurvy. The blood showed 30 per cent. of hæmoglobin, red cells 1,732,000, white 9,200. The wall-paper and surroundings were examined, to exclude the possibility of arsenical poisoning. There were no vomiting or diarrhœa, and no intestinal parasites. The child lost a pound and a quarter a week until oxygen was administered every ten minutes day and night. It was continued six weeks, during which time the hæmoglobin increased steadily.

Dr. Wentworth stated that there was no typical blood in infancy, and although there had been much study of the blood of infancy, but little was really settled. The nucleated red cells were of no consequence. Heart murmurs were rare in infancy.

Dr. Koplik doubted the existence of primary pernicious anæmia. The disease was usually found to be secondary if careful inquiry was made. Babies got well when adults would not. It was difficult to determine if the anæmia was idiopathic in the child.

Dr. Morse agreed that the rules applying to the blood of adults did not apply in children. After a careful examination of all literature, he believed all cases so far described to be secondary.

Dr. Northrup stated that an extensive experience showed him that many children under three years had murmurs, but that rarely was a lesion found at the autopsy.

Dr. Churchill had found endocardial murmurs frequent in both hospital infants and those well-to-do, but regarded them as functional.

Dr. Kerley declared that lesions without murmurs were also frequent.

Dr. Thomson mentioned a case parallel to that of Dr. Rotch, in which the cause was a very weak, modified, and pasteurized milk. The child had the waxy pallor and other changes. A second patient had been fed on laboratory milk, both pasteurized and peptonized.

Dr. Winters spoke of a child fed on sterilized modified milk which recovered at once when put upon young breast milk.

Dr. Rotch, in closing the discussion, stated that the blood had been examined by Dr. Cabot, and by him pronounced to be in every way like that of pernicious anæmia of adults. The murmur had disappeared. As the baby did both well and badly on the same milk, he believed the latter was of proper composition.

So-called Cyclical Albuminuria.—Dr. Frank S. Churchill, of Chicago, reported a case in a girl eleven years old. Albumin was often absent in the morning, but present at night. It disappeared after rest, especially if in bed. Its presence was noted in a large number of boys who ran to college prayers, also in three hundred and sixty-nine boys who exercised on board a training-ship. It was found in soldiers after a march, and in boat crews after training. Two theories of its cause were increase of blood pressure and change in the blood itself. It might be a toxæmia, a tendency toward a condition such as puerperal albuminuria in woman or chronic Bright's disease in man. This child had had an irregular fever, thought to be typhoid. She had had tonsillitis, followed by much pus in the urine. The heart was normal. A chart was presented, showing in detail the result of eighty examinations of the urine in this case. Phosphates ranged high. Specific gravity was high in non-albuminous specimens, and high albumin did not necessarily accompany high urea. Sulphates varied. Chlorides were diminished. Excretion was well maintained, especially of urea. The treatment consisted of the interdiction of meat, the administration of much water and of urotropin.

Dr. Dorning had watched a similar case twenty years. At first albumin appeared every Sunday, later after exertion on any day. Albumin and pus were constantly present now. Albumin was often present in movable kidneys, as shown by Edebohls in a dozen cases.

Dr. Winters related the case of a girl ten years old, who had albumin two years without other symptoms. She was kept in bed four months, during which the albumin disappeared, but only to reappear when she got up. She removed to California, and there went to school, lived like all children, and was free from albumin, which was constantly watched for.

Dr. Koplik warned against the danger of future nephritis in these cases.

An Account of Epidemic Malaria in Children.—Dr. R. G. Freeman, of New York, presented this paper. The cases were seventy-seven in number, and occurred in the children of the New York Foundling Asylum occupying a certain play-room. Though there were seven hundred children in the institution, no others were affected. Those in the nursery-room above did not have it. The temperature ranged from 100° to 105°. All had coated tongues, not red at the edges as in intestinal disorders. None had large spleen. All were given castor oil and put on milk diet. The blood of seven was examined, with negative results at first, though in one instance plasmodium was found later. All received gr. ii. of quinine three times a day, and the temperature fell in twenty-four hours. The oil alone did not cure, so the disturbance was not intestinal. Adjoining the play-room was an excavation, where rains formed stagnant pools. These were present too short a time to permit the development of Anopheles, and neither mosquitos nor bites were found on the children.

Dr. Northrup told of a case of suspected malaria in an infant of nine months, in which the bacteriologist actually killed a mosquito on the infant.

Dr. Packard said that the Anopheles appeared in Philadelphia about June 15th. As influenza had previously prevailed, weakened power of resistance might be a factor.

Dr. Kerley reported that he had examined the blood of fifty children with elevated temperature. None had plasmodium, but all got well on quinine and proper diet. He did not diagnose the trouble as malaria.

Dr. Adams did not consider that malaria was proven, nor evident, except in one case. He saw many cases in Washington, and found the æstivo-autumnal variety required more quinine than others.

Appendicitis in a Child Three Months Old.—Dr. J. P. Crozer Griffith reported a case in a colored girl. There were vomiting and diarrhœa, with mucus and blood in the stools. The child passed into collapse and died after a violent vomiting attack. At the autopsy half the appendix was strangulated and gangrenous. There was evidence of a previous attack, as there was old connective tissue. There was no concretion nor foreign body. The disease was decidedly uncommon in infancy, though not rare in childhood. The author reviewed the fifteen cases published, nine of which had been operated on. Recovery resulted in seven.

Prolonged Laryngeal Stenosis of Uncertain Origin.—Dr. Griffith also reported the case of a child twenty months old, suffering with this condition. It was thought at first to be diphtheria, though no exudate

was seen, nor were Loeffler bacilli found. Cyanosis was extreme, and controlled only by intubation. The child had a rachitic head. The history was that a similar condition had lasted four weeks the year before, and that five others in the family had been affected in a similar manner.

Dr. Rachford had had two cases of persistent laryngeal obstruction, due to œdema below the cords. Intubation failed to relieve, and tracheotomy was done. The child died two and a half months later while intubation was again attempted. A second cyanotic patient was intubated, and tracheotomy followed at once; he wore the tube two months and recovered. A few Loeffler bacilli were found.

Dr. Shaw, of Albany, reported appendicitis in a child seven weeks old, found at autopsy. The appendix had sloughed off. The blood count was 1,250,000 red cells, and hæmoglobin 25 per cent.

Dr. Rotch had seen a choreic condition of the larynx lasting for months. Many cases were diphtheritic, though the culture be negative, and antitoxin should be given. In proof, he cited the case of a child with obstruction of the larynx and negative culture, in which a diphtheritic membrane was found at autopsy.

Dr. Buckingham narrated a case of rickets in which laryngeal voice developed. Three thousand units of antitoxin was given, and recovery occurred in ten days. The culture showed staphylococci only.

Dr. Koplik said that the spasm was not confined to the larynx, but might be accompanied by spasm of the diaphragm.

Dr. Griffith said if we had continuous tetany, why not persistent laryngismus?

Amaurotic Family Idiocy.—Dr. A. C. Cotton, of Chicago, said that thirty-six cases were now recorded, most of them in children of Hebrew parentage. The author's patient was two years old, of normal weight, and without family history of syphilis or consanguinity. The child became gradually blind, had a high palate arch, convergent strabismus, with lateral nystagmus, and could neither sit nor stand. There were also the pathognomonic ocular changes in the macula, idiocy, and paralysis. These patients had a progessive degeneration of the whole nervous system without vascular or inflammatory changes.

Dr. Morse said that more cases were seen than were reported. He had had three cases, one of which was in an American who died at two years of age.

The Little Finger of the Mongolian Imbecile and of Normal Children.—Dr. J. Park West, of Bellaire, Ohio, stated that the characteristic was a short second phalanx, with curving of the finger. The author had noted the fingers of 605 children under nine years of age with the following results: Straight, 18.5 per cent; slightly curved, 29 per cent.; distinctly curved, 33 per cent; markedly curved, 19 per cent. There were five pairs of twins of whom only one pair had fingers alike. Of the nine Mongolian imbeciles seen, only one had the curved fingers, one a straight and a curved.

Dr. Adams mentioned five instances of curved fingers in one family, all very bright.

Maternal Impressions and Hare-Lip.—Dr. B. K. Rachford, of Cincinnati, reported the case of a woman from a tuberculous family who had seven children. Four of these were girls having hare-lip, one to such an extent that the brain could be seen through the roof of the mouth. This child died, but the others lived and were operated upon. The three boys did not have hare-lip. Of these, the first died of tuberculous meningitis when two years old. The mother showed symptoms of tuberculosis, and three times sojourned in California until able to return home apparently well. She ultimately died of tuberculosis. This mother did not believe in maternal impressions, but seemed to know confidently when she was carrying a boy and that he would be born normal. The case of transmitted maternal impression was that of a woman two and a half months pregnant who was operated upon for appendicitis. Violent vomiting after the operation strained the sutures, and stitch abscesses resulted. A nine-pound boy was born in due time, and when he was a year old he began to show marks exactly like the mother's scar, except the line of cut. This increased in distinctness for six months, and so remained.

Dr. Griffith considered the case one of inherited deformity, not impressions.

The Pathological Anatomy of Cretinism.—Dr. F. A. Packard gave the history of a boy six years old, weighing only twenty-seven pounds. He presented the heavy features and all usual evidences of cretinism. From the age of three until five years he had no normal stool. Thyroid extract was given in gr. ¼ doses, and caused improvement in bowels and features in nine days. He began to talk and improved mentally, but died of an acute illness. The necropsy showed atheromatous abscesses in the brain, which was large, fatty liver, granular spleen, cloudy swelling of the heart muscle, and enlarged pituitary body. An interesting point was the presence of calcareous vessels in the thyroid gland.

A Contribution to the Symptomatology of Cretinism.—Dr. Henry Koplik, of New York, presented casts of the hands of a cretin and of a normal child. The cretin presented a prominence separated from the antithenar eminence and giving the hand a square shape. It was suggested that crawling on the hands might have caused enlargement of the os pisiformis underneath, but, as the deformity had been seen at three months, it was probably congenital.

Dr. Cotton remarked upon the rise of temperature in cretins while taking thyroid extract.

Dr. Northrup cited the case of a patient who recovered from pneumonia.

Dr. Christopher cited the case of a cretin dying apparently of tuberculosis. He noted that the patients made rapid improvement, but soon reached a stationary point.

Dr. West reported cretins recovering from bronchitis, and remarked that they improved more in mind than in body.

Dr. Packard emphasized the point that improvement depended upon early beginning.

Dr. Christopher suggested that thyroid might be given for constipation in other patients than cretins.

Regarding consanguineous relationship, Dr. Koplik and Dr. Northrup each reported two cases in cousins.

Glass Sun-Rooms on City Roofs or Winter Play-Houses.—Dr. W. P. Northrup presented photographs and spoke of the many advantages of taking fresh air on the roof rather than in the damp and dusty street.

Dr. Winters said that the large roof garden of the Society for Prevention of Cruelty to Children was very cold, so that it could be enjoyed only by strong boys. Others feared that the roof air would be contaminated by gas from sewer pipes.

Second Day—Tuesday, May 28th.

A Study of Five Hundred and Fifty-five Cases of Summer Diarrhœa.—Dr. C. G. Kerley, of New York, presented this paper. The cases were gathered in dispensary practice and occurred during June, July, August, and September. Of these children, 77 were under three months of age. It was noted that 20 were fed on proprietary foods and 59 upon condensed milk. Four hundred and ninety-nine were treated to the end, of whom 10 died. An invariable rule in treatment was to stop all milk at the outset, to relieve the infected gut; to treat the case vigorously, whether mild

or bad, and to explain to the mother carefully and in writing what was to be done. Barley or rice water was commonly given. Egg mixture plus brandy was atrocious. By dextrinizing the gruels might be given double the usual strength. The tannin products had failed. The four reliable drugs were calomel, castor oil, bismuth, and opium; calomel particularly when vomiting occurred. Irrigation was often overdone. The mothers should be educated and proper feeding all the year round insisted upon. The author urged that the municipal government provide milk laboratories, ice, and even district nurses.

Dr. Griffith said he had abandoned astringents, and used opium to prevent peristalsis.

Dr. Koplik was surprised at the reflections upon albumen water, which he found most useful. Dextrinized gruels were best after vomiting had ceased. The details of food as to quantity and character must be under the immediate control of the physician, as, *e.g.*, at the Good Samaritan Dispensary, where two hundred patients were supplied daily.

Dr. Buckingham cautioned against the government having control of the food supplies, especially the formulæ, and dissented from the reflections upon alcohol.

Dr. Holt urged rest, and cited a case of irrigation kept up for seven months. The mucous stools ceased with the cessation of the treatment. The medicine should be magnesia, followed by opium.

Dr. Winters urged further the importance of stopping milk for a time. He had long ago discarded cereals: if not good for the well, how could they be good for the sick baby? The non-use of alcohol he believed to be incompatible with success. Weak milk would maintain the infant.

Dr. Adams found rules useless for most mothers. All food should be suspended for twenty-four hours, and then it must be remembered to put nothing into the digestive tract which may be indigestible. Salines alone would maintain life for several days. He advocated cereals, egg water, castor oil, etc., but did not use bismuth.

Dr. Cotton said it was important to know distinctly the purpose of rectal irrigation in a given case; whether it was to stimulate peristalsis, to stimulate the moribund, to act as a sedative in fever, or only to remove offending matter in the bowel.

Dr. Dorning emphasized rest from irrigation and medicine, but especially change of air to sea or mountain. He had had two cases of arsenical poisoning from bismuth.

Dr. Rotch said that the poor were entitled to as good treatment as the rich; therefore the latter should be urged to give money for supplying milk laboratories for the former. He would give for the attack of diarrhœa sterilized water and alcohol at the outset. Functional cases needed stimulants. The food should be mixed with precision.

Dr. Wentworth said that, although there were no lesions macroscopically, there might be microscopically; also that it was impossible to make a clinical diagnosis correspond to the nomenclature based on lesions.

Dr. Saunders said he gave eggs and cereals, also brandy and wine, and tea sometimes in place of alcohol. He advocated broths first and beef juice later. Of drugs, chloral was one of the best for pain, to be combined with aromatic rhubarb. One dose of atropine would stop serous discharges.

The Feeding of an Incubator Baby.—Dr. C. W. Townsend, of Boston, related a case a point in which was that the baby increased in weight better after changing from Jersey to Ayrshire milk. Cereals were found better after six months than before.

The Place of Cereals in Infant Feeding.—Dr. Henry D. Chapin said that it was true that the use of cereals was not necessary and unscientific. Using cow's milk instead of mother's was not following nature, as there were differences other than chemical. There was much yet to understand in milk—the two sugars, the soluble and insoluble proteids, etc. Tables were shown giving the latest analyses of milk from various animals, herbivora (ruminating and non-ruminating), carnivora, etc. While appreciating the great value of percentage feeding, we must remember that cow's milk would not be mother's milk. The flocculi were not the same. The curd of cow's milk was best broken up by a cereal that had been dextrinized; the curds then became soft, not leathery. Gruel should be made of one tablespoonful of flour to one pint of water. Milk could be added to the gruel in proportions to suit the digestion of the infant until unmodified milk was taken. Chemistry was not the only basis of comparison. With this treatment the tendency was to return to a milk diet rather than to a proprietary food.

Dr. Morse said that, while it was possible to bring babies up by hand, breast milk should be had if possible.

Dr. Rotch considered the one-per-cent. cereal solution too weak for nutrition, and unnecessary as a diluent. Better results might be obtained by prescribing proteids from whey albumin rather than the total proteids of milk. These, being soluble, needed no cereal to break the curd.

Dr. Koplik said there was a sharp distinction to be made between the baby healthy or ill, and if ill, whether it be a chronic or acute intoxication. Any modification of milk would keep up intestinal toxication. Putting a small amount of sugar and a dextrinized cereal in the milk made the baby grow; that was the test. There was too much attention given to the mixtures and too little to the processes in the intestine.

Dr. Kerley said that some babies could not take proteids strong enough for their needs, and strong gruels were food in themselves.

Dr. Griffith said that no one was entirely right nor all wrong; the fact being that each man became proficient in his own methods and modified them as needed, despite scientific principles.

Dr. Holt would dissent from dextrinized cereals for all cases, but welcome it in some. It had no advantages over milk for the healthy. The great principle was to change the food—rational modification.

Dr. Winters said that he used cereals years ago, but he did not believe there was or would be a baby who could not be fed upon milk properly modified. The relation of fat to proteid was more important than the actual percentage of proteid. For example, three per cent. of fat should go with one-half per cent. of proteid, four per cent. of fat with one per cent. of proteid, etc. Cereals added to the intestinal derangements. They were altogether wrong for a healthy baby.

Dr. Saunders spoke of the value of cereals in sick diet, but had no experience with them in the well. He recommended cream and whey mixture in some cases. Scorbutus did not occur in whey-fed children.

Dr. Chapin said he appreciated percentage feeding, but did not wish it to take the place of other good methods. He considered soluble proteids *sub judice*. No part of cow's milk was meant for a baby. Colostrum contained three per cent. of proteids, yet it was recommended to dilute milk to one-third of one per cent.

Third Day—Wednesday, May 29th.

A Monster.—This specimen was presented by Dr. A. C. Cotton. The fœtus had very short extremities, the forearm and legs appearing to arise directly from

the body. A skiagraph showed only one bone in each extremity, probably a femur and humerus. The short clubbed digits were webbed. The great toes and little fingers stood out at angles like thumbs. The wide interparietal space suggested former hydrocephalus. An omphalocele made it seem to be a celosoma. The extremities classed it as phocomelus. The heavy prolabia suggested myxœdema.

Congenital Hypertrophic Stenosis of the Pylorus with Report of Cases and Exhibition of Specimen.—Dr. E. W. Saunders, of St. Louis, was the author of this paper. The child, a girl, was born July 4, 1900. Five days later she had green and bloody stools, eighteen days later she was icteric, and her urine showed uric acid. She vomited one or two hours after every nursing. Nutrition failed. The abdominal organs were found normal at the necropsy, with the exception of the stomach. There was great hypertrophy at the antrum pylori, the length of the pylorus being 2.5 cm., thickness 6 cm. A case was narrated illustrating pyloric spasm as a cause of persistent emesis. In mild cases the spasmodic element was a factor more important than the hypertrophy. Children with pyloric stenosis should be fed upon whey and cream or peptonized milk. Opiates must not be given, rather bromides or chloral.

A Case of Arsenical Poisoning in an Infant of Six Months.—Dr. John Lovett Morse, of Boston, reported this case. The infant was born three weeks prematurely in a collapsed condition. It was placed later in a blue satinet bassinet and fed Walker-Gordon milk. It had a faint systolic heart murmur, had marked pallor, and later cyanosis. The milk was changed to a home modification. The urine had a specific gravity of 1.012, and contained albumin, with blood and hyaline casts. Arsenic was found in the urine and in the lining of the bassinet. It was not found in the wall paper or other articles examined. Improvement was very rapid after removal of the baby to another room. No medicine was given.

Great Fluctuations in Temperature in the Terminal Stage of Pulmonary Tuberculosis.—Dr. Samuel S. Adams, of Washington, reported eight cases in patients under eleven years of age. All had wide temperature ranges, 95° to 105.6°, with no evidence of sepsis or discomfort of any kind. The charts were exhibited. It appeared that whites were more affected than negroes. One child between four and five years old had pulmonary hemorrhage. In surgical cases occurring in tuberculous subjects there were pus and a septic temperature. These patients had neither chill nor sweat.

Dr. Holt said that all temperature curves were exaggerated in a child, and often due to streptococci.

A Note on the Treatment of Hemorrhage in the New-Born by Suprarenal Extract.—Dr. L. Emmett Holt reported a case occurring in a child, twenty-four hours old, who had vomited large quantities of blood the entire day. There were spots of ecchymosis on the body. The cord did not bleed. One grain of the suprarenal extract was given each hour until a total of twelve grains had been taken. It seemed to pucker the œsophagus and hemorrhage ceased.

Dr. Morse related a case in which the suprarenal extracts checked a gastro-intestinal hemorrhage, but the child died of meningeal hemorrhage. In another case of oozing from the bruise of a forceps blade there was no benefit. It was necessary to use Monsel's solution and digital pressure for hours.

Prolonged Pyrexia from an Unusual Cause.—Dr. L. Emmett Holt reported this case. The temperature ranged as high as 106°. Intestinal disturbance was present, but was never severe. Indefinite signs of lung trouble led to the diagnosis of pneumonia. Examination of the sputum and blood gave negative results. The child's weight dropped from twenty-seven pounds to sixteen pounds. After four months the child died. The necropsy showed pus behind the lower lobe of the right lung. There was a sacculated empyema of two ounces of pus on the diaphragmatic side of the lung. The leucocyte count was from 22,000 down to 11,000.

Dr. Rotch, referring to high temperatures, recalled a case in which there was a daily temperature of 106° to 107° F., without physical signs and without plasmodia in the blood. Pulmonary tuberculosis developed later, and the lung was found solid at the autopsy.

Dr. Chapin reported five or six cases of diphtheria of the eye in which antitoxin had been used, but he considered that the vigorous application of ice was a great factor in the cure.

Dr. Carr stated that suprarenal extract must be always in aquous solution in order to insure good results. The local effect was seen in ten seconds, and the internal effect in ten minutes, if at all.

Dr. Wilson related a case of purpura with hemorrhage from the nose, mouth, and bladder. Five-grain doses of suprarenal extract caused immediate arrest of the bleeding.

Dr. Rotch reported cases which emphasized the danger of not giving antitoxin at once in cases of diphtheria of the eye.

Dr. Kerley reported cases of rhinitis of long duration cured by 1,000 units of antitoxin. The Klebs-Loeffler bacilli had been found, though there were no other symptoms of diphtheria.

Measles Complicated by Appendicitis.—Dr. Harold Williams, of Boston, reported the case of a child, twelve years old, who had never been strong, and who had had measles previously. In four days the temperature reached 104.5° and the eruption appeared. On the second day there had been vomiting, and on the third day abdominal pain; on the fifth day the pain was such that an operation was done for the appendicitis. On the sixth day the temperature fell to normal, and recovery was complete.

Physical Measurements in Puberty, their Significance, Variation, and Applications.—Dr. W. S. Christopher, of Chicago, read a paper based upon six thousand examinations of Chicago school children. The six charts showed many interesting truths. Boys increased in stature from seven to nine years and from seventeen to eighteen years. There was a relative quiet from nine to twelve years of age. Boys' weight, grip, and endurance rose at puberty as did vital capacity. Vital capacity fell in girls at this period. There was shown to be an exaltation of power at puberty, preceded by a rest period. Increase in height ceased, but grip, endurance, and vital capacity increased after puberty. This was the time when the weak failed and the strong forged ahead. It was a period of high morbidity, when anæmias and cardiopathies developed. There was a lack of balance, and the child was on the borderland of physical insolvency. This lack of balance could often be observed in the facial expression.

Dr. Holt said it was most important to establish normals in comparisons of this kind. He had found it profitable to keep measurements of his office patients, as by watching the growth of a child he could better advise as to exercise, school, or place to live.

Dr. Christopher laid stress on the necessity of having trained physicians rather than teachers in charge of the tests. For example, the teachers reported a very small percentage of children with defects of vision, while an expert found that thirty-two per cent. of six-year-old boys were so defective, and thirty per cent. of thirteen-year-old boys.

Election of Officers.—This resulted in the following choice: *President*, Dr. W. S. Christopher, of Chicago; *First Vice-President*, Dr. Charles W. Townsend,

of Boston; *Second Vice-President*, Dr. John Dorning, of New York; *Secretary*, Dr. Samuel S. Adams, of Washington; *Treasurer*, Dr. J. Park West, of Bellaire, Ohio; *Recorder and Editor*, Dr. Walter Lester Carr, of New York.

The society adjourned to meet in Boston in 1902.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 22, 1901:

	Cases.	Deaths.
Tuberculosis	255	155
Typhoid fever	60	4
Scarlet fever	362	34
Measles	271	9
Diphtheria and croup	239	42
Smallpox	60	20
Chickenpox	57	0
Cerebro-spinal meningitis	0	2

Licensed to Shave.—It has been shown how disease may be transmitted by the razor and other tonsorial implements. In a number of States, notably Michigan, there are laws regulating to some extent the barber's business, and it has been found that they are productive of much good. Mr. Charles Rieger, a member of the Michigan barbers' commission, says of the work of the board: "Some of the questions asked applicants for a license before the board of examiners may sound very simple, but they are important, nevertheless, and must be answered intelligently before the license is granted. For instance, the barber is apt to smile at the apparent simplicity of the question, 'What kind of lather brush do you use? How are the bristles fastened on the handle?' 'That's easy,' he says to himself; but the answers are not always satisfactory. There are certain kinds of handles that gather verdigris and other unhealthful accumulations, and the up-to-date barber will use only those that have proved the best and most cleanly. Another simple question is, 'What do you use for washing lather from a customer's face?' The barber (we occasionally find one) who writes 'a sponge' in the answer blank is advised to cut it out right away, as a most reprehensible practice, and to provide a clean towel for each customer. The question 'What do you use for applying powder to a customer's face?' sometimes elicits the answer 'powder puffs.' This practice is also condemned by the commission. There is no surer method of communicating skin disease than by the application of the same powder puff to each customer's face. The last examination form consists of sixteen questions, upon which the applicant must secure a percentage of seventy. He must be a citizen of the United States, tell how long he worked at the business; whether he served as an apprentice under a regular barber, or just picked up his trade; whether he ever worked in a barber's college, which institutions are not recognized by the profession; on what kind of hone he prepares his razors for use; what kind of solution he uses for disinfecting his razors, clippers, and shears; what he uses for cleaning hair-brushes, combs, and shaving-brushes; how to stop the flow of blood in case a customer is cut; and give his ideas on the best remedies for treatment in skin and scalp diseases, for faces with eruptions caused principally by close shaving, for dandruff, and for loss of hair. The law doesn't expect a barber to be a physician, but it does expect him to be familiar with the best methods of preventing skin disease by the use of proper antiseptics."

Corns.—It sometimes happens that the toes are so pressed and distorted by ill-fitting shoes that they cannot be separated, and the corn is almost beyond your skill. I then recommend amputation of one of the toes at the tarso-phalangeal joint.—Lester Keller.

Phthisis.—Mix gr. xl. of calcium phosphate with ʒ ii. of water and add from ♏ lxxv. to ♏ xcv. of hydrochloric acid; then add balsam of Peru ʒ ss., gum Arabic ʒ ss., creosote ♏ xv., and ʒ iii. of syrup. Give a teaspoonful, gradually increased to a tablespoonful, three times a day.—Schöpp.

Food Value of Alcohol.—Dr. Carl von Noorden, one of the best-known authorities upon dietetic therapeutics, in treating this subject in *The International Magazine*, gives his views upon the value of alcohol as a food. The opinions expressed, proceeding from one who has made a special study of the matter, are undoubtedly of great weight. The eminent German physician says: "As every one knows, there is a mighty movement in all civilized countries against the use of alcohol. The anti-alcohol league endeavors to banish alcohol completely from the human ration. They seek to compass this end partly by forming societies or clubs, partly by educating the masses through public lectures, partly by legislation. They wish to interdict the use not only of strong spirits, but also of the lighter beverages, as wine, cider, beer, etc. The core of the agitation is undoubtedly sound. We have to admit, from the physician's point of view, that just as much harm can arise from wine and beer as from cognac, rum, whiskey, etc. We hope, but it is hardly probable, that the agitation will succeed in limiting the misuse of alcohol to a minimum. Although we desire this very much, yet science must see to it that the fanatical members of the anti-alcohol league shall not hide or pervert firmly established scientific facts in order to favor the interests of their agitation. One of the weapons in the fight against alcohol is the assertion that it is not a food. This is not true. Unobjectionable experiments, carefully thought out, have shown that the greatest part (90 to 95 per cent.) of the alcohol taken is burned in the body. During the oxidation of the alcohol, the oxidation of fat in the body diminishes. In other words, the alcohol, more easily oxidized than the fat, passes to the fore, and hinders the combustion of fat; that is, spares the fat. Something similar would obtain in a stove which one should supply with coal and alcohol. The inflammable alcohol would be the first to take up the available oxygen, so that less would remain for the combustion of the coal, and in this way less coal would be used until the alcohol was consumed. We reckon among the true foods organic substances which are fitted to enter into and become a part of the body, or which by oxidation serve as sources of heat and work. Alcohol lacks the first quality; it never becomes part of the body, and has, so far as we know, no capability of being transformed into fat or carbohydrates. On the other hand, it possesses the second quality in a marked degree. It becomes oxidized, it becomes a source of heat and capacity for work; it saves, in this way, from decomposition and combustion other material which has the capability of becoming a permanent part of the organism. More than this, we know exactly how much fat the alcohol saves from combustion. We know this by comparing its value in calories with the value of fat in calories—1 gm. of fat furnishes the body 9.3 calories; 1 gm. of alcohol furnishes 7.0 calories. The body acquires, therefore, the same amount of 'potential energy' from 70 gm. of fat as from 93 gm. of alcohol, or 93 gm. of alcohol consumed in the body save the expenditure of 70 gm. of fat. This agrees with the observation of every layman,

that those who use much alcohol have a strong tendency to obesity. Exceptions are found only in the case of 'professional drinkers.' The explanation of these cases is that such people lose their appetites and take very little other food. Any one who knows the facts of the oxidation of alcohol and the substitution of alcohol combustion in place of fat combustion, and, in spite of this knowledge, denies the food value of alcohol, sins against the laws of the conservation of energy. This means, in science, as much as is meant in religion by sinning against the Holy Ghost. Although alcohol is a food, no sensible physician would recommend the use of alcohol in the same quantities as fat or carbohydrates, for another quality of alcohol tells against this—its poisonous character. Alcohol is poisonous to the cells, especially to the cells of the nervous system, the liver, the kidneys, and the blood-vessels. The body can, to a certain extent, adapt itself to this as to other poisons, but only within narrow limits. If these limits are overstepped, certain diseases of the cells are sure to follow, causing serious disturbance of the health, and, with many persons, bringing the moment of death nearer by decades. We have no objection to make when men bring before our eyes in glaring colors, by pen and tongue, this great misuse of alcohol; but we must raise our protest when they obscure a physiological fact, the food value of alcohol, and try to make with this falsehood propaganda for a cause which in itself is undoubtedly good."

Cocaine Sniffing.—Cocaine sniffing is said to be on the increase in the South among the negroes. The drug is sniffed up the nose, and the results produced are somewhat the same as those obtained by smoking an opium pipe.

Greater London's Population.—The population of the outer ring of the suburbs of London is 2,042,750 as against 1,405,489 in 1891, 950,957 in 1881, and 631,831 in 1871. The total population of Greater London including the outer ring of suburbs is now 6,578,784. The census of Ireland shows the population to be 4,456,546, a decrease of 5.3 per cent. This is less than during the previous decade. Scotland has a population numbering 4,471,957 persons, while the total population of the United Kingdom is considerably over 41,000,000.

A Voice from the Past.—*The Sanitary Record* says: "The present unsatisfactory state of Cape Town shows the folly of allowing towns, or even villages, to spring up without any regard to the laws of health and good sanitation. Thousands are to-day congregated in that town, and although it is the natural entrance by which emigrants enter South Africa, there is little or no provision for the accommodation of such a class. This fact has brought to the minds of some the memorable words of Sir Bartle Frere, on the event of his departure from the colony, many years ago. His closing words were an earnest plea to the workers of the place to pay attention to the need of providing good houses, such as would be adapted to preserve health and to secure happy homes in a crowded city. 'What constitutes,' he said, 'a good workman's lodging, what provision should be made for adequate water supply, good drainage, and other essentials for health in the building of a house, are matters in which many of your workingmen are masters of their craft. I would ask them to take a patriotic citizen's interest in spreading this knowledge among their less well-informed neighbors and fellows. Let a few of them combine together to provide model lodging-houses for themselves and their families, to influence, so far as they legitimately may, the action of legislation, where legislation is required on the subject, and we may in future hear less of these terrible epidemics which occasionally decimate the younger portion of our population in South Africa, and which are, as you and I know, in the vast majority of instances entirely preventable by reasonable care and adequate sanitary arrangements.' Alas! all were then too much engrossed in the search for riches to heed the good advice, but the people have had to pay heavily for their neglect. An attempt is now being made to reach the ideal set forth by Sir Bartle, but the intervening years have left their mark behind, and much will have to be destroyed before any real good can be accomplished."

Health Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon-general of the United States Marine-Hospital service during the week ended June 22, 1901:

		Cases.	Deaths.
Smallpox—United States and Insular.			
California, San Francisco	June 2d to 9th	1	
Florida, Key West	June 5th	1	
Illinois, Chicago	June 8th to 15th	4	
Indiana, Evansville	June 8th to 15th	1	
Michigan City	June 10th to 17th	2	
South Bend	June 8th to 15th	1	
Iowa, Clinton	June 8th to 15th	1	
Kansas, Wichita	June 8th to 15th	3	
Kentucky, Lexington	June 8th to 15th	1	
Louisiana, New Orleans	June 8th to 15th	11	
Massachusetts, Fall River	June 8th to 15th	1	
New Bedford	June 8th to 15th	..	3
Worcester	June 8th to 15th	8	2
Michigan, Detroit	June 8th to 15th	33	1
Sault Ste. Marie	June 16th	Prevalent.	
Minnesota, Minneapolis	June 8th to 16th	17	
Winona	June 8th to 15th	1	
Missouri, St. Louis	June 2d to 9th	37	1
Nebraska, Omaha	June 8th to 15th	12	
N. Hampshire, Manchester	June 8th to 15th	6	
New Jersey, Jersey City	June 8th to 16th	2	
Newark	June 8th to 15th	3	
Plainfield	June 8th to 15th	1	
New York, New York	June 8th to 15th	102	11
Yonkers	June 7th to 14th	5	
Ohio, Cincinnati	June 7th to 14th	5	
Cleveland	June 1st to 15th	45	
Dayton	June 8th to 15th	1	
Toledo	June 8th to 15th	1	
Oregon, Portland	May 1st to June 5th	23	
Pennsylvania, Philadelphia	June 8th to 15th	3	1
Pittsburg	June 8th to 15th	2	
Rhode Island, Providence	June 8th to 15th	3	
Tennessee, Memphis	June 1st to 15th	26	2
Nashville	June 8th to 15th	1	
Utah, Salt Lake City	June 8th to 15th	9	
Vermont, Rutland	June 8th to 15th	1	
Washington, Hoquiam	June 10th	1	
West Virginia, Wheeling	June 8th to 15th	1	
Wisconsin, Greenbay	June 8th to 16th	6	
Milwaukee	June 8th to 15th	3	1
Philippines, Manila	April 20th to May 11th	18	
Smallpox—Foreign.			
Austria, Prague	May 25th to June 1st	4	
Belgium, Antwerp	May 25th to June 1st	2	
Ceylon, Colombo	May 4th to 11th	..	5
China, Hong-Kong	April 26th to May 11th	5	2
Colombia, Panama	June 3th to 10th	6	
France, Paris	May 25th to June 1st	..	10
Great Britain, Gibraltar	May 24th to June 2d	1	
Glasgow	June 1st to 7th	35	1
Liverpool	May 25th to June 1st	2	
London	May 25th to June 1st	1	
India, Bombay	May 14th to 21st	..	8
Calcutta	May 11th to 18th	..	31
Karachi	May 12th to 19th	4	2
Madras	May 4th to 17th	..	22
Italy, Messina	May 25th to June 1st	..	1
Naples	May 26th to June 2d	169	30
Russia, Moscow	May 18th to 25th	25	1
St. Petersburg	May 18th to 25th	15	
Warsaw	May 11th to 18th	..	4
Spain, Corunna	May 25th to June 1st	..	1
Straits Settlements, Singapore	April 1st to 30th	..	3
Switzerland, Geneva	May 18th to 25th	5	
Syria, Beirut	May 18th to 25th	Few.	
Yellow Fever.			
Cuba, Havana	June 1st to 8th	1	
Cholera.			
India, Bombay	May 14th to 21st	..	3
Calcutta	May 11th to 18th	..	77
Madras	May 4th to 17th	..	6
Plague—Insular.			
Philippines, Cavite	May 2d	1	
Cebu	May 2d	1	
Manila	April 20th to May 11th	94	79
Santa Rosa	May 2d	1	
Plague—Foreign.			
Africa, Cape Town	May 4th to 18th	463	209
China, Hong-Kong	April 27th to May 11th	11,221	209
India, Bombay	May 14th to 21st	..	224
Calcutta	May 11th to 18th	..	79
Karachi	May 12th to 19th	149	144

INDEX.

A

Abbe, Robert, the problem of appendicitis from the medical and surgical points of view, 241.
Abbott, Frank, death of, 624.
Abdomen, contusions of the, 664, 800; early diagnosis and treatment of surgical diseases of the, 666; penetrating wounds of the, 1008; recovery after multiple gunshot wounds of the, 466; surgical treatment of pendulous, 909.
Abdominal cavity, sensitiveness of the, 538; disease, clinical annotations on five cases of right-side, 1025; operations, phlebitis following, 799; operations, pus in, 1016; surgery, local or general anæsthesia in, 826; surgery, objects of drainage in, 307; tumor in an infant, 656.
Abortion, statistics of, 183; tubal, 276.
Abrams, Albert, the clinical value of the heart reflex, 10.
Abscess, follicular and peri-urethral, in man, 684.
Absinthe, legislation concerning, in France, 180.
Accident, official examination in cases of, 743.
Acetanilid, poisoning by absorption from external wounds, 999.
Acne rosacea, suprarenal gland extract in the treatment of, 376; varioliformis, 836.
Acromegaly, cases of, 589, 926; relation of the pituitary body to, 579.
Acroparæsthesia, 953.
Actinomycosis, medical treatment of, 785.
Addison's disease, suprarenal extract in, 107, 956.
Adenitis, cervical, arising from purulent rhinitis, 104; subacute, of the groin, 389.
Adenoid constitution, 148.
Adenoids, 343; accidents in operations for, 1022; after-effects of removal of, 785; etiology of, 1000
Adrenal bodies, adenomata of the, 506; bodies, congenital sarcoma of the, 429; bodies, regeneration of the, 539; extract, see *Suprarenal extract.*
Æsculapius, excavations of the temple of, at Cos, 255.
Agnathia, lingual conditions in, 1010.
Agramonte, Aristides, appointment of, to the chair of bacteriology and experimental pathology in the University of Havana, 659.
Ainhum in South China, 26.
Albumen, nutritious, 425.
Albumin, detection of minute traces of, 712.
Albuminuria, cyclic, 617, 1056; due to constipation and diarrhœa, 815, 1010; in the early stages of syphilis, 700; of nephritic origin, origin of the albumin from the blood, 588; urticaria with, 668.
Albumosuria, 224; myelopathic, 174, 628.
Alcohol, antiseptic action of, 200; disinfecting properties of, 302; effect of, on animal life, 856; food value of, 431, 549, 1060; medical use of, 743; researches on, 466.
Alcoholics, responsibility of, 572.
Alcoholism, depopulation consequent upon, 479; in childhood, 776; war against, in France, 475.
Alexander operation, firm adbesions in, 593
Alimentary stasis and right lateral decubitus, 224.
Alimentation, extrabuccal, 68.
Allen, Charles W., spinal cocainization, 673.
Alopecia, 148.
Aluminum-bronze wire in surgery, 962.
Amblyopia following the use of Jamaica ginger, 63, 479; pathology of toxic, 1009.
Ambulances, means of heating, 546; reckless driving of, 392, 738.
Ambulance surgery, asepsis in, 962, 1052.
American Academy of Medicine, 1053; a local branch of the, 459.
American Association for the Advancement of Physical Education, 660.
American Association of Genito-Urinary Surgeons, 789.
American Gastro-Enterological Association, 821.
American Gynæcological Society, 1013.
American Institute of Homœopathy, 1043.
American Medical Association, 919, 964; general sessions, 919, 923, 929, 971; oration on medicine, 888; oration on State medicine, 898; oration on surgery, 892; president's address, 881; report of the committee on organization, 857, 919, 929, 971; Section on Diseases of Children, 977; Section on Obstetrics and Diseases of Women, 922, 928, 969, 976; Section on Practice of Medicine, 919, 923, 964, 972; Section on Surgery and Anatomy, 921, 926, 966, 973.
American Orthopedic Association, 1005.
American Pediatric Society, 1055.
Amœba coli, staining reactions of, 462.
Ampulla of Vater, primary cancer of the, 347.
Amputation, construction of stumps after, 259.
Anæmia, an extreme case of simple, 650; family history of, 306; pernicious, 629, 671, 733, 752, 867, 924; pernicious, in infancy, 1055; rest in the treatment of, 160; splenic, 104, 503, 538; splenic, with uninuclear neutrophiles, 712; treatment of, 496; with spinal-cord changes, 1045.
Anæsthesia, ether and chloroform (M.S.) mixture for, 259; hysterical, 549; local, in the ear, nose, and throat, 463; report of the committee on, to the British Medical Association, 387; spinal, 176, 382, 426; spinal, proposed new name for, 673; teaching of, 946.
Anæsthetics, deaths from, 135, 747; recent developments in the administration of, 586; relative value of, 871.
Anatomical technique, 927.
Anatomy, study of, 504.
Anderson, William Dexter, death of, 461.
Aneurism, arterio-venous, of the right subclavian, 798; diagnosis of thoracic and cardiac, by the *x*-rays, 629; dissecting, of the abdominal aorta, 667; excision of, 449; following infectious aortitis, 789; gelatin treatment of, 462, 498; of the abdominal aorta in connection with a tuberculous perityphlitic abscess, 305; of the aorta, 676; of the aorta and innominate artery, diagnosis of, and treatment of, by subcutaneous injection of gelatin solution, 68; of the aorta, mediastinal tumor simulating, 589; of the aorta simulating a solid mediastinal tumor, 464; of the aorta, subcutaneous gelatin injections in, 668; of the basilar artery, ruptured, 434; of the middle cerebral artery, sacculated, 435; of the pulmonary artery, 349; of the thoracic aorta, 195; popliteal, cured by digital pressure of the femoral artery, 13; prognosis of aortic, 27; silver wire and electricity in the treatment of, 800; thoracic, diagnosis and treatment of, 69.
Angina epiglottidis anterior, 145; Ludovici, 957; membranous, due to streptococci, followed by paralysis of the soft palate, 854; membranous, produced by other organisms than the Klebs-Loeffler bacillus, 136.
Angioma cysticum of the nose, 462; subconjunctival, 496.
Angioneurotic disturbances, 953.
Angiotripsy, experience with, 65.
Aniline oil, poisoning by, 782.
Ankylosis, almost universal, 914; hereditary, 956.
Ankylostomiasis, a new remedy for, 385.
Anthelmintic enemata, 277.
Anthrax, treatment of, 963.
Antivenene in cobra poisoning, 106.
Antivivisectionist, misstatements of a, 198.
Antrum, opening of the, in empyema, 68; tuning-fork as a test for disease of the maxillary, 507.
Anuria, non-obstructive post-operative, 465.
Anus, fissure of the, 954; rare case of imperforate, 825.
Aorta, ligature of the abdominal, 1002; transverse rupture of the, 1009.
Aortic valve, heart-index interval in regurgitation at the, 345.
Aortitis, infectious, aneurism following, 789.
Aphasia, hysterical sensory, in a child, 390; transient motor, in a left-handed man, 745.
Aphthous fever, treatment of, 787.
Apoplexy in the newborn, 221.
Appendicitis, 920, 921, 926, 961; acute, in the presence of tuberculous peritonitis, 516; cholecystitis simulating, 464; clinical significance of dulness in, 209, 392; complicating hernia in an infant, 655; conditions resembling, 1025; diagnosis of, from typhoid fever, 700; diffuse pelvic exudate in, 31; diffuse peritonitis in cases of, 750; drainage in, 584; gangrenous inflammation of Meckel's diverticulum simulating, 104; hydrogen peroxide in, 476; in a child of three months, 1056; increase of, in Switzerland, 240; in the female, 220; localized abscess resulting from, 551; lymphatic and portal affections following, 494; measles complicated by, 1059; operation for, 539, 787; operative management of retroperitoneal abscess following, 77; problem of, from the medical and surgical points of view, 241; relation of, to diseases of the uterine appendages, 187; subphrenic abscess as a complication of, 452; treatment of, 230, 389; treatment of chronic, 277; tuberculous, 436; value of the leucocyte count in, 776; walling off the pus in, 64.
Appendix vermiformis, anatomical researches in regard to, 566; diagnosis and treatment of abscess in connection with the, 387; primary cancer of the, 596; strangulation of the intestine through an adherent, 1049.
Arctic regions, medicine and surgery in the, 958.
Army, British, medical corps of the, 466, 869; United States, abolition of the canteen in the, 382, 908, 972; United States, dentists in the, 705; United States, report of the Surgeon-General of the, 338.
Arsenic, administration of, 389; elimination of, through the hair, 548; in beer, see *Beer;* in food and drink, 416; poisoning by, in an infant of six months, 1059; toxicology of, 588.

Arterial changes, relation of, to the heart, 708.
Arteries, hypertonus in, and arteriosclerosis, 953.
Arterioles, muscular action of the, 913.
Arteriosclerosis, 597; in a boy of ten years, 1055; intestinal ulceration in, 65; relation of arterial hypertonus to, 953.
Arthritic syndromes in children, 347.
Arthritis deformans, 196; deformans, guaiacol for the pains of, 876; deformans, spinal form of, 756; pneumococcic, 147; treatment of gonorrhœal, 678.
Ascites, detection of slight, through the inguinal canal, 954; due to cirrhosis of the liver, surgical treatment of, 429, 454; treatment of, 635.
Asepsis and antisepsis, principles of, 40.
Ashmead, Albert, should lepers marry? 553.
Aspirin, therapeutic value of, 628.
Association of American Medical Colleges, 1005.
Association of American Physicians, 751.
Association of Military Surgeons of the United States, 910.
Astasia-abasia, hysterical, in a young child, 814.
Asthma, 913; associated with prolapse of the liver, 480; climatic cure for, 708; dyspeptic, 104; etiology of, 292; pathology of, 1000; treatment of, 317.
Astigmatism, detection and correction of, 504.
Asystole, 183.
Ataxia, non-tabetic spinal, 664.
Atherton, A. B., a case of perforating gastric ulcer, 12.
Athrepsia infantum, 145.
Athyreosis in childhood, 66.
Atlantic City (N. J.) Medical Society, 255.
Atomizer, an easy-working, non-spilling, 679.
Atonia gastrica, treatment of, 784.
Atresia hymenalis, 928.
Atropine, antidotal action of, to morphine, 955.
Auditory canal, occlusion of the external, 108.
Auscultatory phenomenon, an inexplicable, 507.
Australia, letter from, 553.
Austria, medical practitioners in, 422,
Austro-Hungarian Hospital of New York, 705.
Auto-intoxication, 709.
Automobiles, regulation of the speed of, 623.
Axilla, hyperidrosis of the, 63.
Axillary artery, composite study of, in man, 956.

B

Babinski phenomenon, 182, 221.
Bacillus aerogenes capsulatus in the human body, 436; pathogenic for rats, 827; tuberculosis, localization of, in the isthmus of the fauces and in the tonsils, 467.
Bacteria, influence of ozone on the vitality of, 426; relation of the morphology of, to virulence, 916.
Bacteriology of healthy organs, 930.
Baker, Richard C., death of, 707.
Baking-powders, an investigation of, 1006.
Baldwin, J. F., three Cæsarean sections—recovery, 851.
Bandler, Samuel W., on the origin of cancer; what remains to be demonstrated, 937; the ovary: its relation to normal functions and to pathological states, 405.
Bangs, L. Bolton, a contribution to the Bottini operation for the radical relief of prostatic obstruction, 367, 394.
Barber shops, antiseptic, in Paris, 984.
Barbers, license laws for, 1060.
Barclay, Peter Moir, death of, 299.
Barker, Henry F., death of, 220.
Bartine, David H., death of, 742.
Bartow, Edward, blunders in caring for parts of the body intended for chemical examination, 351.
Baruch, Simon, the heart reflex and the Nauheim bath, 112.
Bashore, Harvey B., the malarial mosquito on the Susquehanna, 173.
Bates, W. H., the use of the aqueous extract of the suprarenal capsule as a hæmostatic, 197, 207.
Bedsores, application for, 399.
Beer, arsenical poisoning through drinking, 28, 58, 182, 237, 239, 261, 264, 280, 380, 391, 430.
Belding, Almon V., death of, 663.
Bellevue Hospital, presentment of the grand jury respecting the administration of, 213, 218; report of the visiting committee on, 735.
Bellinger, P. L., report of a case of malarial hæmaturia, 635.
Bennett, F. M., death of, 258.

Cornea, rodent ulcer of the, 616.
Cornell Medical College, opening of the new buildings of, 20.
Corus, treatment of, 229.
Cornu cutaneum auris, 1000.
Corporeal specific gravity, value of, in physical diagnosis, 204.
Corrosive sublimate, acute poisoning by, 465.
Corson, Eugene R., *x*-ray photography, 569.
Cortical ganglion cell as an independent organ, 589.
Coryza, local treatment of, 317.
Cough mixture, 317.
Coughing in pulmonary tuberculosis, treatment of, 1010; tubercle bacilli disseminated by, 964; voluntary suppression of, 39, 549.
County medical associations, organization of new, in New York State, 383.
Court held in hospital, 544.
Courtney, J. E., the pupil after death, 349.
Cowgill, Charles A., death of, 258.
Cox, Edwin M., the choice of suture for the patella, 50.
Cox, George W., death of, 663.
Cragin, Edwin B., Cæsarean section, 695, 720.
Craniotomy, technique of exploratory, 14.
Craw-craw, 467.
Cremasteric reflex in sciatica, 958.
Crematorium, municipal, in Great Britain, 179.
Cretinism, pathological anatomy and symptomatology of, 1057.
Crime, cost of, 859.
Crises, gastric, in syringomyelia, 150.
Crothers, T. D., some facts of responsibility in spirit and drug takers, 572.
Crowds, psychology of, 1024.
Crushed extremities, treatment of, by embalming, 108.
Cuba, benign climate of, 311; immigration to, 740; medical history of, 231, 232; sanitary supervision of parts in, 340; scurvy in, 108; salubrity of, 760; vital statistics of, 380.
Curette, use of, in obstetric practice, 970.
Curtis, G. Lenox, a new local treatment for erysipelas, 638.
Cyanosis of difficult explanation, 1045; the late forms of, of peripheral origin, 68.
Cycling for health, 540.
Cylinders, rule for combining crossed, 709.
Cyst, double intraligamentous, 54; papillomatous, in a young child, 699.
Cystinuria, recovery in a case of, 664.
Cystitis, colon bacillus in relation to, 304.
Cystoscopy in women, 236.
Cystotomy, improved method of performing suprapubic, 44.
Cyto-diagnosis of pleurisy, 395.

D

Dalton, Charles, presentation of a medal for heroism to, 580.
Dalton, H. C., wounds of the heart, 745.
Daly, William Hudson, obituary of, 952.
Darwin, ill-health of, 1039.
Davis, N. S., Jr., internal medicine in the nineteenth century, 888.
Deaf-mutes, a helper of, 984.
Deafness, hysterical, 539; systemic factor in catarrhal, 504.
Death certification, 579.
Decidua in abortion, 456.
Degeneration, etiology of, 13, 17; hereditary, 954.
Delirium, paroxysmal, 136; tremens, saline infusions in, 385.
Denslow, Le Grand N., the climate of Long Island, 845.
Dental surgery in the army, 860.
Dentistry, musical, 1023; relation of, to medical education, 304.
Dermatitis, arsenical, 220; blastomycetic, 868.
Dermatology, recent advances in, 547.
Deys, Abraham, death of, 741.
Diabetes mellitus, 261; acid intoxication of, 753; and tabes dorsalis, 276; cutaneous manifestations in, 581; diagnosis and prognosis of, 535, 556; enterectomy in, 508; etiology of, 954; heredity in, 67; in children, 981; modern views of the pathology of, 233; operations on subjects of, 356; pathology and relations of, 346.
Diabetic coma, 118.
Diagnosis, damages for an incorrect, 820; some details of, 104; some sources of error in laboratory clinical, 746.
Diarrhœa, infantile, 733; summer, 1055, 1057.
Diazo reaction in phthisis, prognostic value of, 833.
Diet, effect of, on the secretion of hydrochloric acid and the osmotic tension of the normal human stomach, 959; return of patients to normal, 709.
Digestion, air as a factor in, 824.
Digestive disorders, relation of eye strain and pneumogastric reflexes to, 456.
Digitalis, active principles of, 584; changes in the heart, kidneys, and liver in poisoning by, 960; glucosides of, 259.
Diphtheria, acute dilatation of the heart in, 105; antitoxin of, administered by the mouth, 826; antitoxin treatment of, 146; bacteriological diagnosis of, 425; clinical study of, 224; common source of infection in, 1048; disinfection within or without the body in, 300; failure of antitoxin treatment in a case of, 225; staining of the organisms of, 506; statistics of antitoxin treatment of, 179; treatment of, 188; value of throat cultures in, 964.
Diphtheritic paralysis, apnœa in, 24.
Diplegia, terminal condition in a case of, 31.
Disease, duration of disability after internal, 788; etiology and rational treatment of, 868; prognosis of acute, 466.
Disinfection from a purely practical point of view, 855; of wounds with pure carbolic acid, 825; orchid culture in its relation to a new method of, 493.
Distemper, bacteriology of, 478.
Doctor, the old-fashioned, 478.
Dorr, Samuel Griswold, death of, 707.
Doty, Alvah H., the necessity for a more careful investigation as to the cause of outbreaks of infectious diseases, 281, 308; varicella in adults, 685.
Douche massage, 149.
Draper, William Henry, obituary of, 707; resolutions on the death of, 741.
Dressings, extemporized, 397.
Drinking-water, sterilization of, for armies in the field, 17, 22.
Dropsy, pathology of, 714.
Druggists' insurance against the results of carelessness, 420.
Drug takers, responsibility in, 572.
Drug-taking habits, evils of, 360.
Drurro, John M., death of, 299.
Ductus arteriosus, patent, 829.
Dudgeon, Dr., death of, 461.
Duhring's disease in childhood, 955.
Dunglison, Richard J., death of, 384.
Duodenum, ulcer of the, in an infant, 589.
Dupuytren's contraction, treatment of, 146.
Dysbasia intermittens angiosclerotica, 344.
Dysentery, amœba coli in the causation of, 344; associated with typhoid fever, 549; etiology of, 184, 438, 749; in temperate climates, etiology of, 815; sulphur in the treatment of, 1047; surgical treatment of amœbic, 750; treatment of, 666, 826, 916; treatment of acute, 462; treatment of, in South Africa, 439; treatment of tropical, 712; types of tropical, 546.
Dysmenorrhœa as a factor in determining the character of operations on the uterine appendages, 1014; causes and treatment of, 1049; treatment of, 638.
Dyspepsia, gastro-enteric, abdominal massage in, 915; toxic, of alimentary origin, in second infancy, 506; treatment of intestinal, 837.

E

Ear, acute purulent disease of the, surgical indications in, 169; amyloform in disease of the middle, 24; anomalies of the pinna, 108; an overlooked nasal factor in disease of the, 865; arterial hemorrhage from the, 829; bony defects and fistulæ in the external meatus, 386; congenital atresia of the, 507; cornu cutaneum of the external, 1000; diagnosis and prognosis of disease of the, 504; diseases of the, in scarlet fever, 67; disease of the middle, thrombophlebitis of the sigmoid sinus and brain abscess arising from, 87; diseases of the middle, use of suprarenal extract in, 136; foreign body in the external auditory meatus, 183; furuncle of the external meatus simulating mastoid periostitis, 915; importance to the general practitioner of a knowledge of diseases of the, 62; indications for paracentesis of the drum membrane, 318; non-surgical treatment of diseases of the middle, 868; removal of foreign body from the, 878; removal of the semicircular canals, 388; rupture of the membrana tympani from indirect violence, with concussion of the labyrinth and complete deafness, 426; serous cyst of the auricle, 507; systemic disturbances caused by disease of the, 63; temporo-sphenoidal abscess following suppuration of the middle, 586; treatment of acute inflammation of the middle, 212.
Earth and soil, 427.
Eastern Medical Society, annual banquet of the, 543.
Echinococcus, renal, 374.
Eclampsia, puerperal, 291, 304.
Eczema neuroticum vegetans, 836; origin of, 611; treatment of, 428.
Edebohls, George M., on bandages for nephroptosis, 690, 717.
Edes, Robert T., a family history of anæmia, 306.
Egle, William H., death of, 343.
Einhorn, Max, enteroptosis, 561.
Eisen, Gustav, new method of staining the cancriamœbæ in carcinoma, 672.
Elbow-joint, *x*-ray study of the cause of disability following fractures of the, 190.
Electric light least injurious to the eyes, 983.
Electric shock, a case of, 463.
Ellis, R., asepsis and ambulance surgery, 963.
Elmira Reformatory under new management, 214.
Ely, Leonard W., a few observations from the Lorenz orthopedic clinic, 853.
Embalmers, training-school for women, 267.
Embedding, cups for paraffin, 1022.
Empyema, treatment of, 65, 969.
Endocarditis, cerebral hemorrhage in verrucose, 1009; gonorrhœal, furnishing pure culture of the organism, 465; gonorrhœal ulcerative, 67; pneumococcal, 834; three cases of malignant, 608.
Endometritis, tuberculous, in an infant, 117.

Enteroliths, recto-colonic, 187.
Enteroptosis, 36, 561, 626.
Enuresis in children, treatment of, 207; neurotic form of, 120; rhus glabra in, 495.
Eosinophilia in trichinosis, 1007.
Epidermolysis bullosa hereditaria, 700.
Epididymitis, guaiacol in gonorrhœal, 814; histological process in acute, 427; in typhoid fever, 801; pathogenesis of gonorrhœal, 184.
Epilepsy, bromide treatment of, 318; craniotomy with implantation of egg-shell membrane for, 732; modern surgical and medical treatment of, 46; National Association for the Study of, 580; new symptom of, 13; nitroglycerin in the treatment of, 794; operation in cases of, 757; psychic, 1045; Richet's method of the treatment of, 456; topical treatment of, 1008; Ziehen's modification of Flechsig's opium-bromide treatment of, 24.
Epiphyseal line, injury to the, 586.
Epistaxis, 665; causation and treatment of, in persons beyond middle age, 710; suprarenal extract in, 385, 748.
Erdmann, John F., a method of reducing dislocations of the thumb, 332.
Erysipelas, a new local treatment for, 638; chorea in, 726; treatment of, 301, 390.
Erythema multiforme and vaccination, 866; an unusual case of, 589; resembling smallpox, 629.
Erythromelalgia, 189, 953.
Esophoria, 187.
Ether anæsthesia, 852; a useful preliminary to, 195; death under, 117; effect on the blood of, 796; interrupted, 962; operating in the primary, 390; prevention of some of the evils of, 649.
Ethmoid, abscess of the, 956.
Ethyl-chloride narcosis, 194, 463, 533, 963.
Ethylic alcohol, germicidal properties of, 240.
Eustachian tube, electrolysis in stricture of the, 815.
Euthanasia, a medico-legal study of, 105.
Evaporation baths in the reduction of temperature, 824.
Evidence, medical, 99.
Exophthalmic goitre cured by collodion dressings, 540; danger of operation in, 1042; fright as a cause of, 747; of syphilitic origin, 236, 259; sodium salicylate in, 743; with suppuration of both corneæ, ending in total blindness, 353.
Exsections, 1017.
Eye, cysticercus of the, 347; destruction of, by a shotgun explosion, 425; idiopathic hemorrhage between the retina and the vitreous, 712; mixed treatment with pilocarpine hypodermically in diseases of, 748; treatment of lime burns of the, 878.
Eyeball, modified open treatment after operations on the, 465.
Eyelashes, treatment of falling of the, 399.
Eyelid, emphysema of the, from nasal causes, 503; malignant tumor of the, 1048.
Eye strain, relation of digestive disorders to, 456.

F

Facial paralysis, some of the collateral symptoms of, 378; some of the motor manifestations of, 457.
Fagin, Pierce B., death of, 343.
Faith cures, 715; and the law, 605.
Fallopian tube, genesis of cancer of the, 586; hernia of the, without that of the ovary, 466.
Favus of the nails, 836.
Feeble-minded, education of the sense of touch in, 105; heart and circulation in, 958.
Feeny, John L., death of, 911.
Fees, the doctor's, 785.
Feet, hypertrophic osteopathy of the, 149.
Femur, bloodless treatment of congenital dislocation of the, 668; lengthening of the, by oblique subtrochanteric osteotomy, 625; osteomyelitis of the, 276; spontaneous diastasis of the head of the, 276.
Fever, changes in the chemical composition of the blood in, 589; prolonged, of Nicaragua, 268; simple continued, in South Africa, 1048; the *x*, of the South, 1022; traumatic, 192; treatment of, 539; unclassified type of West African, 223.
Filaria nocturna, development of, in mosquitos, 953.
Filariasis and its consequences in Fiji, 106.
Filtration of municipal water supply, relative merits of slow sand and mechanical, 139.
Finlay, Charles, summary of the progress made in the nineteenth century in the study of the propagation of yellow fever, 201; the mosquito theory of the transmission of yellow fever, with its new developments, 81.
Finger, avulsion of a, in an infant, 386; clubbed, 549, 668.
Fischer, Louis, recurrent vomiting of nervous origin, 645.
Fischer, Martin H., ionization in its physiological and pathological relations, 485.
Fissure, treatment of anal, 639.
Fitzgerald, George Francis, death of, 499.
Flatulence, relation of gastric, to gastro-intestinal catarrhs and chronic appendicitis, 1049.
Floersheim, Samuel, suprarenal extract in hæmoptysis, 508.
Florida cattle disease, investigation of the, 662.
Floyd, Rolfe, an extreme case of simple anæmia, 650.
Foder, Joseph, death of, 620.
Fœtus, extraordinary weight of a, 106.
Food, adulteration of, 620; requirements in various kinds of labor, 959.
Forceps, a new expression, 160; axis-traction, 694, 719; invention and evolution of the obstetric, 103; the axis-traction, 385; use of the obstetric, 240.
Ford, Campbell, the operation for radical cure of inguinal hernia at the end of the century, as I saw it performed by Bassini, Lucas-Championnière, De Garmo, Coley, and Broca, 681.
Foreign body, migratory, 146.
Foster, Henry, death of, 144.
Foundlings, care of, in New York State, 734.
Fowler, George Ryerson, excision of aneurism, with a report of two cases of femoral aneurism so treated, 449.
Fowler, W. E., tuberculosis in prisons and reformatories, 475.
Fox, George H., operation for hernia in children, 715.
Fractures, discussion on, 74; near a joint, management of, 231; new method of treating, 546; of both bones of the forearm, 872; operative treatment of compound or complicated, 263; process of healing in, 943.
France, vital statistics of, 639.
Fraser, Edward Clarence, death of, 502.
Frontal sinus, sounding and irrigating the, 816.
Fruitnight, J. Henry, resolutions on the death of, 62.

G

Gallaudet, Thomas, work of, among deaf-mutes, 984.
Gall stones, causing abscess of the abdominal wall, 146; cholangitis and cholecystitis, complicating, 974; diagnosis of, 665; free ducts in operations for, 225; mortality after operations for, 1048; pancreatitis in, 797; pathogenesis of, 211, 212, 733.
Gangrene, multiple, complicating typhoid fever, 979.
Gasserian ganglion, intracranial extirpation of the, 212; resection of, for facial neuralgia, 866.
Gaston, J. McF., Jr., subphrenic abscess as a complication of appendicitis, 452.
Gastrectasis, gastrojejunostomy in, 192.
Gastric fever in children, treatment of, 230.
Gastric juice, influence of certain alimentary principles in the secretion of, 667.
Gastro-enteric antiseptic, calcium iodate as a, 106; fermentation, relation of indicanuria and oxaluria to, 585; hemorrhage caused by fatty degeneration of the heart, 258.
Gastro-enteritis, bacteriological study of the blood in acute, 320.
Gastro-enterostomy, 798; by the elastic ligature, 181.
Gastroptosis, treatment of, 69.
Gelatin injections, 264; for aneurism, 498.
Gelatinized serum in gynæcology, 428.
Genital organs, prolapse of the, 549.
Genito-urinary examination by the general practitioner, 964; surgery, some retrospects and prospects of, 503.
German army medical service, 294.
German measles, the Duke of York's attack of, 391.
German universities, attendance at, 423.
Germany, growth of population in, 38, 219; increase of cancer in, 437; lengthened medical curriculum in, 18; medical practitioners in, 438; workingmen's insurance in, 951.
Gibney, Virgil P., the treatment of rheumatic and allied diseases of joints complicated by deformity, 321, 353.
Gibson, C. L., an improved method of performing suprapubic cystotomy, 44.
Giddings, Theodore, death of, 21.
Gies, William J., an extreme case of simple anæmia, 650; some facts regarding "ureine," 329.
Giuliana, R. A., tuberculous mastitis, 1037.
Given, S. A. Mercer, death of, 343.
Glanders in Havana, 311.
Glandular ailment at Bacalar Chico, 263.
Glasgow infirmary, reconstruction of, 218.
Glaucoma, effect of shock on, 953; removal of cervical sympathetic ganglion in, 462.
Glottis, spasm of the, in adult life, 1046.
Gloves in operating, 963.
Glycosuria, 556; delicate test for, 225; in children, 262; phenyl-hydrazin test for, 388; tobacco as a factor in, 646.
Glycuronic acid in the urine, 234.
Goelet, Augustin H., the diagnosis and treatment of prolapsed kidney, 841.
Goitre, cancerous, 749; operative treatment of, 22.
Gonococcus in the blood, 389.
Gonorrhœa, 260; chronic, and marriage, 447; diagnosis and prognosis of, 302; generalized infection of, 586, 778, 918; in boys, 982; irrigations of hot salt solution in, 401; modern treatment of, 511; pressure irrigation in the treatment of, 148; protargol treatment of, 628; treatment of, 229; treatment of chronic, 1032; treatment of the early stage of, 221.
Gonorrhœal ulcerative endocarditis, 67.
Goodman, A. L., rapid cultivation of and a differential stain for Loeffler's bacillus, 267.
Gottheil, William S., pityriasis versicolor of the face, 649.
Goundon in South China, 26.
Gout, causation of, 238; causation, prevention, and treatment of, 128; quinic acid in, 428; some manifestations of, 391.
Grace Hospital, New Haven, charges against, 383.
Graham, Percy M., death of, 742.
Grandin, Egbert, axis-traction forceps, 694, 719.
Granular lids, treatment of, 916.
Grassi, Prof. Giambattista, honors to, 545.
Greanellé, W. J., an illuminated vaginal speculum, 877.
Green, Horace, presentation of a bust of, to the New York Academy of Medicine, 271.
Green scours, 1055.

Griffith, Frederic, keloid formed in a vaccination scar, 730; reckless driving of ambulances, 392.
Griggs, Stephen C., death of, 220.
Groin, subacute adenitis of the, 389.
Grove, John H., death of, 584.
Gums, treatment of bleeding and tender, 400
Gunshot wounds in the Philippines, 262; of the chest, venesection in, 710.
Gynæcology, contributions of, to surgery, 977; errors of diagnosis and treatment in, 538; future of, as a surgical specialty, 1018; local applications in, 78.

H

Hæmatemesis, treatment of, 346, 467.
Hæmaturia, a case of malarial, 635; diagnosis of the cause of, 424.
Hæmoglobinuria, 548, 551: bodies in the urine in a case of, 25; etiology of, 657; Koch on, 140; on the Congo, 26; paroxysmal, 146; quinine, 437.
Hæmolysis, 758.
Hæmolytic property of human serum, 1048.
Hæmophilia, antenatal treatment of, 978; examination of the blood in, 960; joints in, 12.
Hæmoptysis from exercise after pleurisy, 397; pseudo-, of naso-pharyngeal origin, 507; suprarenal extract in, 415, 508.
Hæmostasis, electrothermic, in abdominal and pelvic surgery, 928; hepatic, 575.
Hæmothorax, 959.
Haig, Alexander, the causation, prevention, and treatment of gout, 128.
Hallucinations, origin of, 456.
Hancock, James Cole, a new expression forceps, 160.
Hands, disinfection of the, alcohol in, 24; hypertrophic osteopathy of the, 149; surgery of the, 146; tendon transplantation for deformity of the, 357.
Hanks, Horace T., resolutions on the death of, 144.
Hansen, G. Armauer, testimonial to, 860.
Haralson, H. H., ischio-rectal abscess, complicated with gangrene and priapism, 351.
Harelip, association of cleft palate with, 718; maternal impressions in relation to, 1057.
Harlem Medical Association, dinner of the, 736; officers of the, 1004.
Harrogate sulphur waters, therapeutic uses of the, 345.
Havana, sanitation of, 217, 254, 310, 460, 701, 909, 946.
Hawaiian Islands, leprosy in the, 578; objection of the natives to segregation and vaccination, 620.
Hawley, N. J., subarachnoid cocainization in obstetrics and gynæcology, 91.
Hay fever, treatment of, 639.
Hayes, James, death of, 782.
Hayd, Herman E., convulsions with scarlet fever, and the report of a very severe case with perfect recovery, and important deductions from the treatment, 286.
Hayden, James R., conservatism in the diagnosis and treatment of prostatic hypertrophy, 450.
Head, injuries of the, 784.
Health among rich and poor, 541.
Health commissioner of New York State, appointment of the, 381.
Health department, opportunities for young physicians in the, 710.
Health officer, charges against a, 1006.
Health reports of the Marine-Hospital service, 40, 80, 120, 160, 200, 240, 280, 320, 360, 400, 440, 480, 520, 560, 600, 640, 680, 720, 760, 840, 880, 932, 984, 1061.
Healy, Maurice Lauren, death of, 952.
Hearing, functional tests of, 825.
Heart, acute dilatation of the, 666; acute dilatation of the, in diphtheria, influenza, and rheumatic fever, 105; acute dilatation of the, in thermic fever, 426; advanced fatty change of the, 273; affections of the, in middle and advanced life, 627; affections of the, in relation to life insurance, 56; affections of the, of gastric origin, 464; affections of the substance of the, 416; an undescribed sound of the, 751; causes of failure of compensation in diseases of the, 247; condition of the, in the feeble-minded, 958; congenital deformity of the, 115; conservatism in the use of vaso-dilators in certain diseases of the, 187; effect of the distillate of coffee upon the, 54; epilepsy and stoppage of the, 627; fatty, capacity for work in the, 66; fatty degeneration of the, 189, 222, 752, 957; Flint murmur in aortic insufficiency, 751; hydatid of the, 813; influence of arterial spasms upon the, 759; lesions of, in the negro, 966; ligation of the injured coronary artery, 301; neuroses of the, 788; physical examination of the sounds of the, 589; position where the regurgitant aortic murmur is most clearly audible, 953; Potain's method of percussion of the, 722, 759; presystolic murmurs heard at the apex, 1008; presystolic murmur of mitral stenosis, 865; pulsation of the uvula in aortic insufficiency, 1007; reduplication of the first sound of the, 815; reflex and the Nauheim bath, 112; reflex, clinical value of the, 10; relation of vascular disease to disease of the, 708, 823; senile changes in the, 742; stenosis of the tricuspid, mitral, and aortic orifices, 958; stimulant to the, 317; strychnine in weakness of the, 79; suprarenal capsule in diseases of the 823; suture of the, 27, 733; syphilis of the, 548; tonometric examination in chronic diseases of the, 1028; treatment of fatty, 400; treatment of the later phases of disease of the, 220; wounds of the, 27, 745, 870.
Heat-stroke, 147, 148.
Heat, therapeutic application of, 390; treatment of ulcers by, 352.
Hedonal, 550.
Heineman, H. Newton, acute gastric ulceration, 369; the Nauheim treatment, 988.
Hemiplegia, impaired thermic sensibility in, 226; successful trephining in a case of, 263; trophic disorders and disorders of sensation in, 28.
Hemorrhage following the use of chloral, 66; gelatin injections in, 264; leucocyte count in, 924; post-operative, 922; post-partum, 666.
Hemorrhagic infection due to an organism of the bacillus-mucosus-capsulatus group, 629; due to the typhoid bacillus, 22.
Hemorrhoids, elevation of the pelvis in, 540; guaiacol in, 389; new remedy for, 616; operative treatment of, 596; simple operation for, 976.
Hereditary degeneration, 954.
Heredity as a factor in mental deficiency, 952.
Hernia, autoplastic suture in, 967; Bradshaw lecture on, 152; diagnosis of diaphragmatic, 1046; inguinal, 192; inguinal, tube and ovary in an, 70; local anæsthesia in operations for, 538; of the adductor longus muscle, 468; of the urinary bladder, 986; operation for, in children, 715; operation for inguinal, in a diabetic subject, 355; operative treatment of umbilical, in adults, 803; radical treatment of, 261, 681; radical treatment of inguinal, 161; radical treatment of inguinal and femoral, 799; radical treatment of inguinal, in a child two weeks old, 355; radical treatment of umbilical, 799; relief of strangulated, by taxis, 784; resection of bowel for strangulated, 262; strangulated in infants, 355, 612; treatment of gangrenous, 506; ventral, following abdominal section, 149; woollen-yarn truss in infantile, 300.
Heroin, therapeutic value of, 317, 628.
Hertzberg, R., the self-limitation of infectious diseases, 29.
Hess, Ralph J., death of, 499.
Hiccough, hysterical, cured by etherization, 53.
Hill, Horace G., death of, 299.
Hill, L. L., wounds of the heart, 870.
Hingston, Sir William, honors to, 1005.
Hip, affections of the, 301; hæmostasis and amputation at the, 966; operative treatment of congenital luxation of the, 616, 628; typhoid, 153.
Hip-disease, cause of shortening after, 222; hysterical, measurements in the diagnosis of, 746; operative management of, 77; tuberculous, amputation at the hip for, 154.
Hodgman, Abbott, death of, 343.
Hoffer, Jacob E., death of, 502.
Holstein, Mrs. Anna Morris, a famous army nurse, death of, 61.
Hopkins, George W., superheated air in the therapeutics of chronic catarrhal otitis media, 849.
Hood, William Taliaferro, death of, 584.
Horses, epidemic among, 1043.
Hospital appointments for women, 708.
Hospital Graduates' Club, annual dinner of the, 910.
Hospitals, cost of, 560; small, and their administration, 566; proposed change in the management of the New York City, 15, 60.
Hot-bed, use of, in Korea, 745.
House of Mercy Hospital at Pittsfield, 621.
Houston's valves, pathological condition of, 235.
Huber, John B., faith cures and the law, 605.
Humerus, fissure of the upper end of the, 516.
Hunt, Oren George, death of, 21.
Hunterian oration for 1901, 430.
Hydatids of the heart, 813; primarily affecting the lung, 106; wandering, 495.
Hydrocele, eversion of the tunica vaginalis in, 465; guaiacol in, 389; inversion of the tunica vaginalis for, 791; ovarian, 655.
Hydrocyanic acid, disinfection by, 786.
Hydrosalpinx, torsion of, 549.
Hydrothorax, right-sided, 751.
Hygiene and sanitary science, progress and tendency of, in the nineteenth century, 898; in early life, 983.
Hyoid and thyroid, bony junction of the, 850; bone, loop around the, as an aid to narcosis during certain operations on the lower jaw and mouth, 956.
Hyperidrosis of the axilla, 63.
Hyperpyrexia, nervous, following parturition, 262.
Hypnotism extraordinary, 1024.
Hypospadias, 72.
Hysterectomy, a difficult, 79; for uterine cancer, 1015.
Hysteria, prognosis of, 63; successful moral treatment of, 875; unusual case of, 788.
Hysterical anæsthesia and analgesia, 188.

I

Ichthyosis, congenital, 960.
Idiocy, amaurotic family, 1057.
Ileus due to vascular obstruction, 550.
Illinois State Medical Society, 947.
Imbecile, little finger of the Mongolian, 1057.
Immunity, 590, 625; inheritance of acquired, 786.
Impetigo contagiosa bullosa, diagnosis of, 39; treatment of, 277.
Incomes of medical men in Berlin, 840.
India, census of, 740; use of opium, ganja, and intoxicating drinks in, 478.
Indiana State Medical Society, 910.
Indigestion, intestinal, 4; of loneliness, 1038.
Inebriates' Home, a proposed, 661.
Infancy, morbid phenomena in second, in

relation to a toxic dyspepsia of alimentary origin, 506; pulse in, 958.
Infant feeding, 181, 189, 221, 222; cereals in, 1058; elimination of starches in, 953; with breast milk in whole or in part, 686, 717.
Infections, natural resistance to, 184; rôle of, in women, 191.
Infectious disease, necessity for a more careful investigation as to the cause of outbreaks of, 281, 308; self-limitation of, 29.
Inflammation, deep-seated, ichthyol in, 425, 469.
Influenza, 97; acute dilatation of the heart in, 105; appearance of the soft palate a pathognomonic sign in, 912; bacillus of, 440; bacteriological study of some of the complications of, 303; cerebrospinal meningitis due to, 960; cinnamon in, 1009; in Chicago, 907; in infants, 520; laryngeal complications of, 828; of the nervous system, 147; polyneuritis following, 183; puerperal, 999; pulmonary complications of, 711; quinine as a prophylactic, 1009; streptococcus bronchitis in, 912; streptococcus infection after, 816; treatment of, 158, 181.
Inglis, Roy, death of, 707.
Inhalation of atomized liquids, 955.
Inheritance, theories of, with special reference to the inheritance of acquired conditions in man, 913.
Injury, vitality after severe, 1009.
Insane, duty of the State in the care of the, 55; in general hospitals, 1040; nursing the, 930; relationship between chronic renal disease and the condition of excitement and depression in, 576; surgical operations on the, 542.
Insanity associated with pelvic disease in women, 72; borderland of, 304, 807; early diagnosis of, 191; ephemeral, 786; periodical, 301; plea for a more rational treatment of, 944; prevention of, 425; puerperal, 503, 656, 1045; relief of, after treatment for cataract, 25; religious, 256; statistics of, 278; study of, in New York State, 59.
Insects as conveyers of infection, 213, 311.
Insomnia in heart disease, treatment of, 455; tea and coffee causing, 119; treatment of, 293.
Institute for Medical Research, 907, 911, 971, 1004.
Institutionalism, abuses of, 1054.
Instruments, sterilization of, 720.
Internal medicine in the nineteenth century, 888.
Intestinal anastomosis, 463; indigestion, 4; obstruction, diagnostic differences in three forms of, 231; obstruction, differential diagnosis of, 62; obstruction, intestinal juice in the treatment of, 27; obstruction, Meckel's diverticulum as a source of, 706; obstruction, treatment of the, 54, 465; sand, 508, 576.
Intestine, action of atropine on the, 23; bellows injection for obstruction of the, 591; cases of surgery of the, 829; Connell's suture of the, 75; knot within the lumen in surgery of the, 927; obstruction of the, 831; operations for perforation of the, 193; paralysis of the large, 1048; perforation of the, 475; prevention and relief of postoperative obstruction of, 1, 30; traumatic rupture of the, 441; tuberculous infection of the, 27; ulcer of the duodenum of embolic origin, 118; ulceration of the, in neurasthenics, 65; unilateral exclusion in fistula of the, 549.
Intoxications, classification of, from a pathological point of view, 753.
Intubation of the larynx, prolonged, 980; retention of the tube in a case of, 511; traumatism during, 181.
Intussusception, diagnosis and treatment of, 548; resection for chronic, 355.
Iodine, allotropic, 539.
Iodipin reaction in gastric diseases, 959.
Iodism, acute, and its relation to the rhodan of the saliva and nasal and conjunctival secretion, 66.
Iodoform, calcium iodate as a substitute for, 106.
Iodophilia, 1007.
Ionization in its physiological and pathological relations, 485.
Iris, tuberculosis of the, 864.
Isaacs, A. E., a whistle in the œsophagus, 404.
Ischiopagus, a case of, 303.
Ischio-rectal abscess complicated with gangrene and priapism, 351.
Isotonia, 733.

J

Jacob, Archibald Hamilton, death of, 215, 238.
Japan, hospitals of, 944.
Japanese dancing mice, equilibrium control in, 668.
Jarvis, George C., death of, 782.
Jaundice in children, 816; in typhoid fever, 147; leucocytic reaction in a case of, 711.
Jelks, James T., surgical treatment of abdominal dropsy following cirrhosis of the liver, 454.
Jewett, Homer O., death of, 220, 299.
Jews, comparative pathology of the, 584.
Johns Hopkins Hospital, bedside work in, 796.
Johns Hopkins University, the presidency of, 951.
Johnson, R. Erskine, death of, 583.
Joints, classification and diagnosis of some affections of the, 387; treatment of rheumatic and allied diseases of, complicated by deformity, 321, 353.
Jones, I. Newton, death of, 343.
Jones, Mary Dixon, the origin of fibroid growths of the uterus, 267.
Josephson, J. C., malaria in a child of three weeks, 635.
Jugular vein, ligation of the internal, 145.

K

Keloid formed on a vaccination scar, 730; traumatic, of the median nerve, 149.
Kemp, Robert Coleman, a new instrument for the prostate; for massage, inunction, and the application of electricity combined, 318.
Kentucky State Medical Society, 950.
Kenworthey, William B., the use of suprarenal capsule in hæmoptysis, 415.
Keratitis, prevention of interstitial, 188.
Keschner, Moses, a case of membranous angina due to streptococci, followed by paralysis of the soft palate, 854.
Kidneys, amyloid degeneration of the, 107; basement membrane of the tubules of the, 956; calculi of the, scratch-marks on wax-tipped bougies in the diagnosis of, 1020; cancer of the calices, 960; congenital absence of the, 273; congenital cysts of the, 436, 982; diagnosis and surgical treatment of prolapsed, 841; diseases of the, in infancy and childhood, 982; echinococcus of the, 203, 374; etiology of primary contrasted, 184; floating, 259, 800, 913; floating, a method of fixation of, 283; floating, bandages for, 690, 717; floating, in children, 709; floating, nonsurgical treatment of, 711; floating, treatment of, by massage, 870; gelatin injections for the relief of hemorrhage from the, 225; histological changes in the, from corrosive-sublimate poisoning, 376; horseshoe, 196; idiopathic abscess of the, 952; ligature of the blood-vessels of the hilum, 375; nephrolithotomy on both, 800; nephrotomy for hemorrhage of the, 667; removal of large cyst of the, 435; rupture of the, 785; significance of the intrinsic blood-vessels of the, in nephrotomy, 303; skiagraphic diagnosis in surgery of the, 967; succussion of the, 225; surgical infections of the, 76; surgical treatment of tuberculous, 1020; traumatic movable, 65; tuberculosis of the, 677, 913; unilocular echinococcus of the, 550; various incisions in operations on the, 929; *x*-ray diagnosis of calculus of the, 790.
King, Alfred, a successful pylorectomy on a man in his seventy-first year, 730.
King, Charles Roy, death of, 583.
Kings County Medical Society, library of the, 861.
Kinnicutt, Francis P., orchitis and epididymitis in typhoid fever, 801.
Kirk, Lewis R., death of, 663.
Kitchen, J. M. W., orchid culture in its relation to a new, improved, and completely effective method of disinfection, 493; causation of rheumatism and gout, 238.
Knee jerks in chorea, 952.
Knee joint, quiet effusion into the, 387; treatment of contractures of the, 1010.
Knights of St. John of Jerusalem, 621.
Knopf, S. A., tuberculosis in prisons and reformatories, 334.
Kober, George M., the progress and tendency of hygiene and sanitary science in the nineteenth century, 898.
Kohlstock, Prof. Paul, death of, 661, 820.
Koller, Carl, case of thrombophlebitis of the left sigmoid sinus masking a latent brain abscess in the left temporosphenoidal lobe, both arising from chronic otitis media, 87.
Kubin, Wilhelm Karl, the importance of aseptic vaccination, with remarks on vaccination in general, 524, 555.

L

Labia majora, pedunculated fibroid of the, 433.
Labor, see *Childbirth*.
Labyrinth, spongifying the, 376.
Lacrymal diseases, radical treatment of, 104.
Lanehart, Louis N., small hospitals and their administration, 566.
Laparatomy, local anæsthesia in, 538.
Laryngeal whistling, 665.
Laryngectomy under eucaine anæsthesia, 149.
Laryngitis, infantile, 375; influenzal, 588; treatment of tuberculous, 359.
Laryngologist, limitations of the, in the general treatment of nose and throat diseases, 746.
Larynx, cancer of the, 915; cancer of the, extensive operation for, 67; fatal scalding of the, 302; fatal stenosis of the, following intubation for papilloma, 469; hemorrhage from an apparently normal, 867; implantation of Thiersch skin grafts for the cure of stenoses of the, 375; indications for intralaryngeal operations in cancer of the, 467; intubation of the, see *Intubation*; papilloma of the, in children, 195; postdiphtheritic stenosis of the, 194; prevention of auto-extubation, 827; prolonged stenosis of, of uncertain origin, 1056; radical cure of malignant disease of the, 424.
Lavage, use and abuse of, 13.
Laveran, Dr., honors to, 1051.
Lead poisoning in lapidaries, 65; treatment of, by electricity, 480.
Lee, Lucius J. W., death of, 103.
Leech, J. Stuart, death of, 180.
Legs, explanation of the equal length of both, 346.
Leper hospital at Jerusalem, 625; opposition to the Louisiana, 860.
Lepers, marriage among, 476, 553.
Leprosy, chaulmoogra oil in, 631; in France 949; in the Hawaiian Islands, 578; localization of the bacillus of, in the different organs, 612; treatment of, by ichthyol, 866; treatment of nerve, 786.
Lesley, William Wood, death of, 62.
Leszynsky, William M., coffee as a beverage, and its frequent deleterious effects

upon the nervous system: acute and chronic coffee poisoning, 41, 70; recurrent oculomotor paralysis; report of a case, with remarks, 812.
Letters from Australia, 553; from Constantinople, 198, 632, 1052; from London, 28, 68, 111, 152, 197, 237, 264, 305, 348, 391, 430, 474, 508, 552, 590, 630, 671, 714, 742, 782, 828, 869, 917, 961, 1011, 1050; from New Zealand, 198, 1012; from Paris, 474, 631, 743, 870, 1051.
Leucocytosis, changes in bone marrow accompanying, 588; digestive, 813; varieties of, 40.
Leukæmia, acute, 829; acute lymphatic, following malaria, 916; acute, without macroscopic pathological changes in the blood-forming organs, 302; splenomyelogenic, 392; the blood in lymphatic, 677.
Levien, Henry, the proper solution of the spitting nuisance, 672.
Liell, Edward N., subarachnoid spinal cocainization as a means of inducing surgical anæsthesia, 728.
Life insurance, congress of examiners for, 951; examinations for, 710; for total abstainers, 948; heart disease in relation to, 56; medical aspects of, 437.
Lincoln, H. W., the treatment of gastroptosis, 69.
Linderman, Robert J., death of, 62.
Linsley, J. H., death of, 299.
Lipæmia, cause of, 234.
Liquid air, medical possibilities of, 300.
Liver, cancer of the, at the age of twenty-four years, 262; cirrhosis of the, 925; cirrhosis of the, in a boy of eight years, 185; congenital sarcoma of the, 429; enlargement of the spleen in cancer of the, 1010; etiology of cirrhosis of the, 668; iron in the, 960; massive cancer of the, 376; movable, 787; primary cancer of the, 676; primary sarcoma of the, 13; recovery from acute yellow atrophy of the, 712; retention cyst of the, 70; syphilis of the, 832; treatment of abscess of the, 26; tropical abscess of the, 784.
Lobster, poisoning by canned, 827.
Loeffler's bacillus, rapid cultivation of, and a differential stain for, 267.
London, growth of, 931; letters from, 28, 68, 111, 152, 197, 237, 264, 305, 348, 391, 430, 474, 508, 552, 590, 630, 671, 714, 742, 782, 828, 869, 917, 961, 1011, 1050; population of, 1061; vital statistics of, for 1900, 256; water supply of, 474, 508.
Loneliness, indigestion of, 1038.
Longevity in Spain, 479.
Long Island, climate of, 760, 845.
Loomis Laboratory, litigation over the, 822; Sanatorium, charitable annex to the, 580.
Lorenz orthopedic clinic, a few observations from the, 853.
Loveland, B. C., aneurism of the pulmonary artery, with report of case, 349.
Ludwig's angina, 957.
Lumbar puncture for detecting the presence of tubercle bacilli, 667
Lunacy commission, requirements for the presidency of the, 178; commissioners, passage of a bill regarding, 381; law, opposition to proposed changes in the, 258.
Lungs, cancer of the, 119; deposit of calcium phosphate in the, 223; diffuse gangrene of the, 273; foreign body in the, 667; primary cancer of the, 273; primary hydatids of the, 106; surgery of the, 968.
Lupus erythematosus, phototherapy of, 347.
Lupus vulgaris, 679; galvano-cautery treatment of, 235; phototherapy of, 551; treatment of, 301; treatment of, in London, 1004; treatment of, with thyroid extract, 319; tuberculin in the treatment of, 23, 200; *x*-ray treatment of, 211, 235, 247.
Lymphadenia, treatment of, 329, 425, 504.
Lymphatic ganglia, rôle of, in infection, 915.
Lyon, Samuel K., death of, 741.

M

McClelland, William F., death of, 624.
McCullough, John W. S., tetanus, 472.
McDonnell, R. A., syphilis in the well-to-do, 727.
McElroy, Rufus, bellows injection for intestinal obstruction, 591.
McKellops, Henry Byron, death of, 707.
McKelvey, James Boyd, death of, 144.
Mackenzie, John R., catarrhal pneumonia in children, 348.
McKinley, Mrs., illness of, 946.
McWilliams, Clarence A., hernia of the adductor longus muscle, with operation, 468.
Mack, William A. M., death of, 103.
Madura foot, 309.
Magness, George Hosmer, death of, 1044.
Maine, new hospital for the insane in, 59.
Malaria, acute lymphatic leukæmia following, 916; alterations in the parasites of, during treatment with methylene ble, 827; and mosquitos, 26, 124, 158, 172, 212, 263, 347, 388, 702, 960, 1003; autochthonous, in Buffalo, 14; benign tertian, without fever, 1049; bubo complicating 1047; campaign against, 427; discovery of the plasmodium of, 856; disturbance of the soil favoring, 263; dysarthria and myasthenia in, 960; epidemic, in children, 1056; estivo-autumnal, with unusual symptoms, 3, 30; etiology of, 551; general paralysis due to, 14; in a child of three weeks, 635; intermittent neuroses due to, 960; intestinal complications of, 310; Koch on, 24, 103, 140; nephritis of, 755; parasitology of, 68, 465, 712; pernicious comatose, 866; prevention of, 103, 223, 256, 422, 819; rapid method of staining the parasite of, 436; serum treatment of, 199; some facts bearing upon the problem of, 471; some phases of, 920; variations in the figured elements of the blood in, 960.
Malarial coma in a boy, 108; ulcers, 26.
Malformation, a case of, 586.
Malignancy, acute traumatic, 665.
Malta fever in Havana, 309.
Manassein, V. A., death of, 583.
Manges, Morris, the causes of failure of compensation in diseases of the heart, 247.
Manhattan Dermatological Society, 142, 679, 836.
Manila, hospital corps instruction in, 949; San José medical college in, 20.
Marasmus, 145.
Marcy, Erastus Edgerton, death of, 61.
Marine hospital service, 710.
Marmalade, glucose adulteration of, 943.
Marriage, regulation of, 176, 500, 577, 624, 739.
Martin, Robert J., death of, 1006.
Marx, Simon, the toxæmia of pregnancy, 601, 659; version: indication, technique, and limitation, 692, 719.
Massage, douche, 149.
Mastication, effect of, upon the gastric secretion, 29.
Mastitis adolescentium, 302, 588; and tumor formation, 111; puerperal, 815; tuberculous, 1037.
Mastoid disease, furunculosis of the external auditory meatus simulating, 915; operations, 344; operations, retaining the skin of the posterior meatal wall in, 507.
Maternal impressions, 1057.
Maxilla, sarcoma of the inferior, twenty years after partial resection, 872.
Measles, 977; appendicitis complicating, 1059; Koplik's spots in, 261.
Meat, pathological conditions found in, 547.
Meckel's diverticulum, gangrenous inflammation of, simulating appendicitis, 104.
Medals, gift of medical, to the Boston Medical Library, 640.
Mediastinal tumor, intermittent fever as a symptom of, 428.
Medical Association of Georgia, 706.
Medical Association of the Greater City of New York, 313.
Medical curriculum, the first-year, 1053; education in the United States, early, 839; institutions, lay management of, 1054; legislation, uniform, 840; practice, bill to regulate, 238, 307; practitioners, crusade against unlicensed, in Minnesota, 339; science, progress of, 232; science, State endowment for the advancement of, 141.
Medical Society of the County of New York, 34, 233, 397, 555, 717.
Medical Society of the State of New York, 185; business commitee of the, 1042.
Medical Society of the State of West Virginia, 949.
Medico-Chirurgical College and Hospital of Philadelphia, trustees of the, 178.
Melancholia, toxic origin of, 721, 753.
Mellinger, Henry S., death of, 258.
Meningitis, acute serous, 788; bacteriology of cerebrospinal, 953; epidemic of cerebrospinal, in Bergen, 108; following croupous pneumonia, 538; influenzal, 427, 960; posterior basic, 349; syphilitic basilar, 587; tuberculous, analysis of the symptoms of, 33.
Menopause, fallacies concerning the, 105.
Menorrhagia in young girls, 313; of pelvic origin, electricity in, 260.
Menstruation, age of first, in the United States, 1014; nature of, 1014; normal, 956.
Mental disease and toxæmia, 120; disease, rest in bed in the treatment of acute, 112; disease, syphilitic, 184; deficiency, heredity as a factor in, 952; depression, influence of, in the development of cancer, 795; development, etiology of arrested, 785; fatigue in school children, 826; sanitation, 14.
Merriam, Frank C., resolutions on the death of, 220.
Metabolism, defective, in relation to the mucous membranes, 135; influence of salicylates upon, 758; in old age, 496; in the child, 656.
Metacarpal fracture, 519.
Metric system, 173, 439; opposition to, in England, 197.
Metritis, chronic, 677.
Metrorrhagia, 313; due to inflammatory processes in the pelvis, 385; persistent, 386.
Microbes in the human body, 1037.
Migraine, prevention of, 260; surgical treatment of, 736.
Milk, danger in boiled, 40; effect of high temperature on the casein of, 303; general antitoxic properties of, 438; goat's, 472; impure, in Paris, 500; infectious disease spread by, 867; sterilization of, 220.
Miller, E. S., death of, 299.
Miller, H. T., the clinical significance of dulness in appendicitis, 209, 392.
Milnes, G. H., death of, 29.
Mineral waters in France, 631.
Minich, Andrew K., death of, 823.
Minnesota, crusade against unlicensed medical practitioners in, 339.
Miscarriage, postural treatment in threatened, 732.
Mississippi State Medical Association, 948.
Missouri State Medical Association, 947.
Monster, an anencephalic, 433; a specimen of, 1058; prehistoric, 278.
Montefiore Home for Consumptives, opening of the, 911.
Montfort, Robert V. K., death of, 21.
Montreal, death rate of, 423.
Moor, William, death of, 783.
Moore, William, a strange request, 1013.
Morbus cœruleus, 108.
Morphine, antidotal action of atropine, 955.
Morphinism, 1046.

Morris, Edward Watts, death of, 707.
Morris, Robert T., a method of fixation for loose kidneys, 283; hydrogen peroxide in appendicitis, 476; notes on ovarian grafting, 83; on faith cures, 715.
Moschcowitz, Alexis V., strangulated hernia in infants: description of a hitherto unrecognized cause and seat of strangulation, 612.
Mosquitos and malaria, 26, 124, 158, 212, 263, 347, 388, 702, 960, 1003; and yellow fever, 58, 81, 201, 269, 1042; history of Anopheles, 1023; hybernation of, 748, 786; in Paris, 743; protection against the, 58, 60, 738, 821; resistance of the larval, to cold, 666; transportation of, in baggage, 1013.
Mother, a very young, 423.
Mount Sinai Hospital, annual report of, 704; laying the corner-stone of the, 822.
Mountain fever, 664; sickness, 68.
Mouth, sepsis of the, as a cause of "septic gastritis," "toxic neuritis," and other septic conditions, 211.
Mucous membranes, defective metabolism in relation to the, 135.
Mumps, a sign of, 666; treatment of, 546.
Murmur, systolic, in the second left interspace, 872.
Muscle, auscultation of the normal and pathological sounds of, 272.
Myasthenia gravis, 958.
Mydriasis, alternating, 588.
Myelitis, diagnosis and pathology of acute, 150.
Myers, Walter, death of, 299.
Myocarditis and fatty degeneration of the heart, 752; chronic, 957; treatment of chronic, 496.
Myocardium, diseases of the, 584; in infections, intoxications, and poisoning, 616.
Myopia, amount of, corrected by removing the crystalline lens, 504; lack of uniformity in prescribing glasses in, 393.
Myrtle, James A., death of, 1050.
Myxœdema, enlargement of the sublingual veins in infantile, 552; of varied type, 825.

N

Nævus, 679.
Nails, diseases of the, in pregnancy, 958.
Nammack, Charles E., treatment of acute sero-fibrinous pleurisy, 373, 395.
Naphtha, poisoning by coal-tar, 223.
Napias, Henry, death of, 870.
Narcolepsy and obesity, 826.
Narcosis, regular breathing in beginning, 250.
Nasal discharges, significance of, in children, 878; polypi, non-myxomatous character of, 132; septum, correction of deviation of the, 624; septum, necessity of post-operative treatment after removal of spurs of the, 63; surgery, use and abuse of the galvano-cautery in, 576.
Nauheim treatment, 988.
Naval warfare, care of the wounded in, 1038.
Navy, medical men in the, 709; report of the surgeon-general of the, 417.
Neck, phlegmon of the, 708.
Negro problem, discussion of the, 662.
Neill, Leo E. F., death of, 583.
Neoplasms, causation of, 505.
Nephrectomy for adenocarcinoma, 790; for rupture of the kidney, 785.
Nephritis, 303; character of the cells in the exudation in acute, 224; clinical aspects of chronic, 777; malarial, 755; operation for calculous, 973; treatment of scarlatinal, 1007.
Nephrolithotomy, double, 800.
Nephroptosis, bandages for, 690, 717.
Nephrorrhaphy, non-absorbable suture in, 446; with flap fixation, 998.
Nervous and mental diseases, hospital for the special treatment of acute, in New York City, 100; diseases, significance of bodily work in the institutional treatment of, 390; system, treatment of diseases of the, 629.
Neuhoff, F., the treatment of pneumonia, including the hypodermic injection of saline solution, 724.
Neuralgia, facial, caused by a hair irritating the membrana tympani, 345; remedies for, 399, 400; trigeminal, 598.
Neurasthenia, climatology of, 222, 815; excretion of urine in, 65; failure to recognize the true nature of, 753; hæmatology of, 665; of otic origin, 375; toxic origin of, 721, 753; treatment of, 474.
Neuritis, localized, complicating typhoid fever, 146; of the brachial plexus, section of the posterior spinal roots for the relief of pain in, 135; post-typhoid, 153; recurrent alcoholic peripheral, 666.
Neuropathies of the extremities, 212.
Neuroses, occupation, 925; pathology of the so-called functional, 456, 618; so-called traumatic, 192.
Newborn, injuries to the head in the, 1020; intracranial hemorrhage in the, 221; pathology of the, 625; spoon-shaped indentations of the skull in, 182; treatment of hemorrhage in the, by suprarenal extract, 1059.
New Jersey Board of Medical Examiners, steps toward reciprocity taken by the, 458.
New Jersey, the insane in, 658.
New York Academy of Medicine, 36, 113, 156, 271, 354, 431, 513, 592, 673, 831; library of the, 102; Section on Medicine, 158, 395, 556, 759; Section on Obstetrics and Gynecology, 113, 432, 593, 718; Section on Surgery, 193, 355, 516, 675.
New York City, growth of, 931; revised charter of, 659.
New York County Medical Association, 70, 235, 393, 596, 716.
New York Medical Society for Clinical Research, 460.
New York Medico-Surgical Society, 499.
New York Neurological Society, 31, 357, 875.
New York Pathological Society, 115, 195, 273, 434, 676, 833.
New York State board of charities, 418.
New York State Hospital for the care of Crippled and Deformed Children, opening of the, 820.
New York State, recent legislation in, of interest to the medical profession, 879; the new medical bill for, 377.
New Zealand, letter from, 198, 1012.
Night blindness, liver in the cure of, 26.
Nineteenth century, advance of science in the, 140.
Noma in advanced age, 955; report of two cases of, 955.
Nome, health of, 499.
Nose and throat, general bodily resistance as a factor in disease of the, 504; cause of suppuration in the, 879; conditions of the, in the aged, 864; hereditary syphilis of the, 107; hyperæsthesia of the mucosa of the, 750; ocular expression of diseases of the, 824; operation for deformity of the, 708; primary chancre of the, 784; restoration of the, in hypertrophic acne, 712; throat, and conjunctiva, relation existing between diseases of the, 1008; treatment of collapse of the alæ, 586.
Nott, Eliphalet, death of, 180.
Nurses, complaints against, 306; total abstinence for, 508.
Nurses' Associated Alumnæ of the United States, incorporation of, 660.
Nursing, female, tribute to the efficacy of, 423.
Nutrition, albuminous, 425.
Nystagmus of spasmus nutans in infants, 587.

O

Oatman, E. L., cups for paraffin embedding, 1022.
Obese, metabolism in the, 27.
Obstetrical operations, the major, 300.
Obstipation, 1045.
Occupation neuroses, 925.
Ocular expression of intranasal lesions, 824.
Oculomotor paralysis, recurrent, 812.
Œdema, wandering, 1009.
Œsophagitis, membranous, 106.
Œsophagus, diverticulum of the, 757; peptic ulcer of the, 549; whistle in the, 404.
Ogilvie, Leslie, death of, 384.
Old age, metabolism in, 496.
Ollier, Prof. Leopold, monument to, 423.
Omentum, cyst of the, 752.
Operation, adhesive rubber dam for the prevention of possible infection at the site of, 746; preparation and after-care, 519, 962.
Ophthalmia neonatorum, douche in the treatment of, 63.
Ophthalmophacometer, 187.
Opium, treatment of poisoning by, 539; use of, in Asiatic countries, 55, 265.
Opotherapy in China and Indo-China, 150; in gynecology, 865.
Optic nerve, primary glioma of the, 50; thalamus, tubercles in the, 65.
Oral sepsis in gastric affections, 1049.
Orbit, cavernous angioma of the, 665.
Orchid culture in its relation to a new method of disinfection, 493.
Orchitic extract, composition and action of, 956.
Orchitis complicating typhoid fever, 756, 801.
O'Reilly, Thomas, death of, 343.
Osteomalacia, 388, 629.
Osteopaths, medical examination for, 378.
Ostitis deformans, 756.
Otitis media, chronic purulent, 575; superheated air in the therapeutics of chronic catarrhal, 849.
Otomycosis in the tropics, 23.
Otorrhœa, treatment of chronic, 386.
Ovarian cysts, enucleation of, 1043; cysts, intraperitoneal rupture of simple, 304; hydrocele, 655.
Ovaries, anatomical and physiological evolution of the, from the embryo to the aged woman, 71; as organs of internal secretion, 956; conservative operations in the, 624; relation of the, to normal functions and to pathological states, 405; transplantation of the, 72, 83, 292, 928; tumors of the, 506, 594, 718.
Ovulation and menstruation not interdependent, 260.
Oxalic acid of the organism, 954.
Oxygenated water, danger of the use of, when catgut sutures have been used, 878.
Oysters, some of the properties of, 599.

P

Palate, operative treatment of cleft, 25, 878.
Pan-American Exposition, emergency hospital for the, 599.
Pan-American Medical Congress, 231, 266, 267, 308.
Pancreas, abscess of the, 184; cancer of the head of, simulating epithelioma of the stomach, 587; enlargement of, simulating biliary colic, 23; retrojection of the bile into the, 956.
Pancreatitis, 797; acute, 425; acute hemorrhagic, 956, 957; experimental, 479; interstitial, 196; recovery after operation for acute, 425.
Panhysterokolpectomy, 1016.
Pani ghao, water sore, or sore feet of Assam coolies, 26, 466.
Paraffin, subcutaneous injections of, 588; uses of, in bacteriological work, 276.
Paralysis agitans, trauma as an exciting cause of, 865; agitans, treatment of,

229, 539, 639; agitans without tremor, 815; Duchenne-Erb type of upper arm, following multiple neuritis, 505; facial, some of the collateral symptoms of, 378; facial, some of the motor manifestations of, 457; family periodic, 757; infantile, treatment of, 23; juvenile general, with hereditary syphilis, 65; of the spinal accessory, 358; possibility of a cure of progressive, 292; pseudo-hypertrophic muscular, 305; recurrent oculomotor, 812.
Paramyoclonus multiplex, 1008.
Paraplegia, family spasmodic, 28.
Pardee, Edward L., death of, 144.
Paris, letters from, 474, 631, 743, 870, 1051; medical students in, 951; water supply of, 475.
Park, Roswell, the recent Buffalo investigations regarding the nature of cancer, 761, 794.
Park, William Hector, opium taking in Asiatic countries, 265.
Parotid gland, tuberculosis of the, 959.
Parotitis, infective, after abdominal section, 106, 182; suppurative, complicating pneumonia, 637.
Parturition, nervous hyperpyrexia following, 262.
Pasteur, statue of, 478.
Patella, choice of suture for the, 52; treatment of fractures of the, 229, 873.
Patellar reflex, new method of obtaining the, 66.
Pathological Institute, trouble in the, 661.
Pathological Society of Philadelphia, 21, 102, 421, 460, 544, 662, 706, 781, 863.
Pathology, embryological basis of, 546.
Payne, Redmond W., report of a case of primary glioma of the optic nerve, 50.
Peabody, George L., a case of æstivo-autumnal fever with unusual symptoms, 3, 30; some fallacies of therapeutics, 481, 511.
Peking, unsanitary conditions in, 177, 547.
Pelvic and abdominal surgery, combined operations in, 386; disease, indications and limitations of the vaginal route in the attack on, 188; inflammatory masses, removal of, by the abdomen, after bisection of the uterus, 303; suppuration, 432; surgery, accidents and complications of, 923; tumors, strangulation of, by torsion of the pedicle, 954.
Pelvis, bad positions of the, productive of spinal curvature, 304; fracture of the, 25.
Pemphigus neonatorum, a case of, 463.
Penis, cancer of the, 675; double, 516; gangrene of the, 182.
Pericarditis, 965.
Pericardium, adherent, 966.
Peritoneum, origin of colloid carcinoma of the, 435; primary endothelioma of the, 833.
Peritonism an indication for laparotomy, 54.
Peritonitis, acute, 959; acute diffuse septic, resulting from appendicitis, 548; following rupture of a duodenal ulcer, 352; from perforation of the appendix, recovery after operation for, 787; gonorrhœal, 680; operation for perforative, 710, 711; prevention of surgical, 923; surgical treatment of diffuse suppurative, 389; tuberculous, 107, 148; tuberculous, acute appendicitis in, 516; tuberculous, benefit of operation in, 517, 519; tuberculous, in an infant, 117; tuberculous, treatment of, 505; tuberculous, vaginal and abdominal incision in, 225.
Peritonization in laparotomy, 389.
Peritonsillar abscess, 221.
Perityphlitic abscesses, opening of, in Douglas' sac by parasacral section, 302.
Perkins, E. Stanley, death of, 782.
Perkins, Maurice B., death of, 1006.
Pertussis, see *Whooping-cough*.
Pessary, the glass-ball, 114.
Peterson, Frederick, appointment of, on the lunacy commission, 779.
Pettenkofer, Max, death of, 384.
Phagedæna, treatment of, 53.
Phalangeal joints, absence of certain, 956.
Pharmacopœia of the United States of 1900, 504.
Pharmacy law, the new, 61.
Pharyngo-mycosis, pathology of, 856.
Pharynx and nasopharynx, sclerotic hyperplasia of the, 627; cancer of the, in a boy of fourteen years, 292; fatal scalding of the, 302.
Phelps, A. M., radical cure of inguinal hernia, 161.
Philadelphia County Medical Society, 20, 142, 179, 461, 545, 622, 741, 822, 862.
Philadelphia Hospital, appointments to the, 180; resident physicians at the, 950.
Philadelphia Medical Club, 102.
Philadelphia Medical Journal, editorial changes on the, 57.
Philadelphia Neurological Society, 219, 380, 544, 739.
Philadelphia Pediatric Society, 102, 297, 663, 860.
Philanthropy and scientific medical progress, 439.
Philippines, fevers of the, 784; scarcity of medical officers in the, 439; United States army pathological laboratories in the, 344.
Phlebitis following abdominal operations, 799.
Phloridzin diabetes, 234.
Phosphatic concretions beneath the skin, 292.
Phototherapy with ultra-violet rays, 867.
Phthisis, diminishing prevalence of, 1023; effect of wind exposure on, 147; open-air treatment of, at home, 711; prognostic value of the diazo reaction in, 833; rest cure in, 305; treatment of vomiting in, 399; venous injections for, 111; see also *Consumptives*, *Pulmonary tuberculosis*, and *Tuberculosis*.
Physicians, mortality and morbidity of, 53; strike of, in German cities, 1003.
Piffard, Henry G., the uric-acid problem, 744.
Pigmies in Africa, 199.
Pill-scratching, 673.
Pinta, 467.
Pirrie, E. E., death of, 343.
Pituitary body, relation of the, to acromegaly, 579.
Pityriasis rosea, 679; versicolor, Allen's iodine test in, 912; versicolor of the face, 649; versicolor of the palms, 836.
Placenta, paralysis of the site of the, 588; prævia, 314, 626; prævia, a case of complete, 300; prævia, Cæsarean section in cases of, 976; prævia or detached placenta, 173; prævia, relative merits of bipolar version with slow extraction, and accouchement forcé in the treatment of, 1020; ulcer of the, 393.
Plague, 503; a study of, 754; discoverer of the bacillus of, 783; in various places, 20, 79, 197, 264, 341, 381, 383, 391, 419, 424, 500, 501, 624, 703, 706, 737, 780, 1044; measures for combating, in Penang, 839; precautions against, in Great Britain, 828; prophylactic and curative treatment of, 292; relation of rats to the, 818; treatment of buboes in, 680; typhus-like and other eruptions in, 263.
Plantar reflex, 182.
Plasmon, 318.
Pleura, hemorrhage into the, 752.
Pleurisy, discussion on, 395; due to Eberth's bacillus, 150; primary cancer of the, 273; pulsating, 955; treatment of acute sero-fibrinous, 373, 395; treatment of purulent 65; typhoid, 67.
Pneumectomy and pneumotomy, 968.
Pneumonia, atypical, pulmonary tuberculosis following, 1046; bacteriology of lobular, 677; bloodletting in, 575; catarrhal, in children, 348; creosote in, 492; etiology and treatment of, 63; following ether anæsthesia, 865; ice-pack in the treatment of, 546; in infants and children, abortion of, 211; pseudomembranous exudate on the mucous membranes in a case of, 752; streptothrix, 755; suppurative parotitis complicating, 637; treatment of, 148, 186, 465, 724, 788, 913.
Pneumonotomy, 800.
Pneumopyopericardium, 628.
Pneumothorax, surgical, pulmonary insufflation for the prevention of, 798.
Poliomyelitis, acute anterior, among adults in Guam, 279.
Polymyositis, 960.
Polypi, nasal, extending to the pharynx, 1000; non-myxomatous character of, 132.
Pond, Erasmus A., an operation for the relief of stoppage of the tear passage, abscess of the sac, etc., 172.
Porro-Cæsarean operation, 188.
Potain, Professor, death of, 181.
Potatoes, poisonous alkaloid in, 278.
Potter, J. B., death of, 198.
Pott's disease of the spine, abscesses of the abdominal wall simulating, 974; fracture, operations for deformities following, 188.
Practice, reciprocity in medical, 418.
Practitioners' Society of Orange, N. J., 102.
Practitioners' Society of New York, 30, 153, 174, 352, 511, 872.
Pregnancy, albuminuric retinitis in, 654; chorea during, 708; disease of the nails in, 958; extra- and intra-uterine, 636; extra-uterine, 36, 113, 114, 190, 971, 1008; extra-uterine, diagnosis of, 79, 595; hæmatoma of the abdominal wall complicating, 616; hyperæsthesia of the uterus during, 733; primary ovarian, 197; retinitis albuminurica in, 208; toxæmia of, 601; tuberculosis in relation to, 54; tumors complicating, 224, 346, 719.
Prepuce, tumors of the, 107.
Prickly heat, prevention of, 916.
Prize, the Belilios, for essay on tropical medicine, 780; the Edward N. Gibbs, 737; the Sivewright, for essay on tropical medicine, 780.
Profanity, psychology of, 539.
Profession, medical, relation of the public to the, 521, 592.
Progressive muscular atrophy, morbid anatomy of a case of, which was clinically one of amyotrophic lateral sclerosis, 876.
Progressive paralysis, possibility of a cure of, 292.
Prognosis of acute disease, 466.
Prophylaxis, individual, 585.
Prostate, Bottini operation for the relief of enlarged, 367, 394; cancer of the, 118; conservatism in the diagnosis and treatment of hypertrophy of the, 450; new instrument for treatment of affections of the, 318; new operative method of exposing the, 393; operations for enlargement of the, 967, 1045; primary cancer of the, 466; relief of senile hypertrophy of the, 793; relation of, to the fecundative power of the spermatic fluid, 586; suprarenal extract in hemorrhage of the, 915; treatment of gonorrhœal congestion of the, 837.
Prostatectomy, 793.
Prostatitis, chronic, reaction of the prostatic fluid in, 149.
Prostitution, discussion on, 397, 819, 954.
Proteids, precipitation of certain, by bacteria, 835.
Proteolysis, quantitative tests for, 504.
Prurigo, 836.
Pruritus ani, treatment of, 359; senile, treatment of, 136; vulvæ, treatment of, 230.
Pryor, William R., an improved method of examining the female bladder, admitting intravesical operation and treatment of the ureters, 327.
Psycho-physical laboratory, a national, 908, 1006.
Psychosis following pelvi-abdominal operations, 466.
Pterygion, pathogeny and pathological anatomy of, 505.

Ptosis, easy operation for congenital, 587.
Puberty, physical measurements at, 1059
Public, relation of the, to the medical profession, 521, 592, 715.
Puerperal eclampsia, 976; at the sixth month, 304; latent, with no premonitory symptoms of uræmic poisoning, 291; morphine in, 427; prevention of, 855; saline infusions in, 917, 1047; treatment of, 538.
Puerperal influenza, 999.
Puerperal insanity, 503, 656, 1045.
Puerperal mastitis, 815.
Puerperal peritonitis, diplostreptococcus in the etiology of, 212.
Puerperal sepsis, antistreptococcus serum in the treatment of, 106, 390, 747; indications for hysterectomy and for abdominal section and drainage in, 181; pathology of, 253; prevention of, 79, 970; treatment of, 34, 169, 970.
Pulmonary artery, aneurism of the, 349; obstruction, vicarious absorption of oxygen in, 615; œdema, acute, 336.
Pulmonary tuberculosis, ano-rectal fistulæ premonitory of, 184; as a cause of death, 293; explanation of the vulnerability of the apices in, 1008; hydriatic treatment of, at home, 916; in early childhood, 64; management and treatment of, 94; N and O therapy in, 305; Nordrach treatment of, in Ireland, 551; operative treatment of, 390; prevention of, in predisposed children, 980; pulse rate of, 953; temperature fluctuations in the terminal stage of, 1059; tracheal injections in the treatment of, 259; treatment of cough in, 1010; treatment of, in hospitals and among the poor, 137; see also *Consumptives*, *Phthisis*, *and Tuberculosis*.
Pulse in infancy, 958.
Pulsus paradoxus, reversed, due to aneurism of the aortic arch, 748.
Pupil, appearance of the, after death, 348.
Purdy, Charles Wesley, death of, 144.
Purple, S. S., memorial address on the late, 832.
Purpura as a symptom, 639; fulminans, 789; hæmorrhagica, bichloride of mercury in, 226; hæmorrhagica from auto-intoxication, 310.
Purrington, W. A., the new medical bill, 266.
Pyelitis from Eberth's bacillus, 576.
Pylorectomy for carcinoma, 576; on a man in his seventy-first year, 731.
Pylorus, congenital hypertrophic stenosis of the, 495, 1059; disappearance of a tumor of the, after gastro-enterostomy, 627; hypertrophic stenosis of the, 835; prognosis of cancer of the, after gastro-enterostomy, 550.
Pyonephrosis of typhoid origin, 788; painless, 508.
Pyorrhœa alveolaris, 1037.
Pyosepticæmia, cryptogenic, 668.
Pyramidal tract, functional significance of the, 1010.
Pyrexia, drug treatment of, 979; prolonged, from an unusual cause, 1059.

Q

Quackery, 520; prize essay on the dangers from, 296.
Quacks, crusade against, in New York, 102.
Quakers, longevity of, 298.
Quarantinable diseases, bacteriological commission for the study of, 310, 312.
Quarantine, inspection of the New York, 1003.
Queen Victoria, illness and death of, 141, 177, 178, 348.
Quinine, exanthemata due to, 68; subcutaneous injection of, 827.

R

Rabies, rarity of, in Constantinople, 1052.
Radiographs, technique and correct interpretation of, 155.
Radiography, instantaneous, 392.
Radius, fissure of the head of the, 194.
Rats and the plague, 422, 818; pathogenic bacillus for, described by Danysz, 827; production of bacterial disease in, 931.
Raynaud's disease, a case of, 511.
Raynor, Nathan, death of, 220.
Reardon, H. D., death of, 181.
Reciprocity in medical practice, 418, 458, 1053.
Rectum, cancer of the, 193, 675, 927; foreign body in the, 428; new operation for prolapse of the, 193; resection of, per vaginam, 344; treatment of cancer of the, 858; Red Cross Hospital in New York City, 298.
Reed, Charles A. L., the president's address delivered at the fifty-second annual meeting of the American Medical Association, held at St. Paul, Minn., June 4–7, 1901, 881.
Regeneration, physical, of the human race, 931.
Relapsing fever in Sumatra, 1049.
Renal colic with the passage of urethral casts, 106; insufficiency without disease of the kidneys, 258; surgery, 585.
Repair, process of, in damaged tissues, 24.
Reptilian delusions, 54.
Resections, 1017.
Respiration, effect of the distillate of coffee on the, 54.
Responsibility and crime, 826.
Retina, embolism of the central artery of the, partial recovery from, 574; glioma of the, 959.
Retinitis albuminurica in pregnancy, 208, 654.
Retroperitoneal cyst, 262.
Retropharyngeal abscess and adenitis, 108; in the adult, 221.
Rheumatic affections, discussion on, 630, 671.
Rheumatism, acute dilatation of the heart in, 105; affections simulating, 925; atypical case of, 135; bacteriology of, 391, 787, 1040; epidemiology of, 150; etiology and pathology of, 824; etiology of acute, 238, 375; in relation to the throat, 376; pathology of, 150; petroleum massage in acute articular, 262; relations of the chronic rheumatic and rheumatoid affections to acute infective, 505; symptomatology of, 867; treatment of, 149, 639; treatment of the heart in acute, 397.
Rheumatoid arthritis, pathology and treatment of, 627.
Rhinitis, purulent, causing cervical adenitis, 104.
Rhinorrhœa, 263.
Rhoads, M. Albert, death of, 742.
Rib, cervical, 1009.
Rice, Charles, death of, 782.
Rice, William, death of, 299.
Rinderpest in the Philippines, 582.
Robin, A., a new saccharometer and ureometer combined, 477.
Roby, James W. E., death of, 1044.
Rockefeller's foundation of an institution for medical research, 907, 911, 971, 1004.
Rodent ulcer, 187; *x*-ray treatment of, 345.
Roentgen rays, alleged death from, 69; diagnosis by means of, 479; in cancer of the breast, 1009; malpractice with, 839; photography, 569; value of, in medicine, 156, 215, 497; without electricity, 620.
Rogers, John, Jr., experiences with tracheotomy, 641.
Roofs as play-grounds, 1057.
Roosa, D. B. St. John, the relation of the public to the medical profession, 521, 592.
Rosacea, 836.
Rose, A., splashing sound and atony, 1012.
Rose, William Meadows, death of, 299.
Ross, Charles Austin, death of, 384.
Ross, J. J., death of, 742.
Ross, John Dean, death of, 424.
Rosse, Irving C., death of, 741.
Roussel, Albert E., report of three cases of malignant endocarditis: one following measles, another typhoid fever in a child and simulating lymphatic leukæmia, and another terminating in recovery, 608.
Rumbold, Thomas F., death of, 864.
Rundle, George Lester, death of, 144.

S

Saccharin, action of, on digestion, 319.
Saccharometer and ureometer combined, 477.
Sacral plexus, perineuritis of the, 429.
Sactosalpinx hæmorrhagica, 595.
Safford, Lillian R., death of, 144, 180.
Saline solutions, 962.
Salpingitis, gonorrhœal, 677; suppurative, 677; tuberculous, in an infant, 117.
Salt sickness of cattle, investigation of, 662.
Samoan Islands, census of the, 863.
Sanatorium, ancient, 838; and hotel in Chicago, 946; for consumptives in Hartford, 947.
Sanitary treaty, an international, 737.
Sanitation and quarantine, 267; municipal, 426; need for more efficient, 337.
Sarcoma cutis, 716; late results of the treatment of inoperable, with the mixed toxins, 794; round-cell, of the thigh, 195.
Saunders, Sedgwick, death of, 264.
Saunders, Sir Edwin, death of, 590.
Sayre, Lewis Albert, memorial address on the life of, 113.
Scabies, treatment of, 591, 837.
Scarlet fever, aural complications of, 67; convulsions with, 286; diphtheria antitoxin in, 776; infection of, 1047; transmission of, to a cat, 827; treatment of the nephritis of, 1007; virulence of the contagion of, 955.
Schleich's anæsthetic mixture, modified form of, 838.
School-girl, pubescent, 983.
School-room, the sanitary, 304.
Schott, Theodor, tonometric examination in chronic diseases of the heart, 1028.
Sciatica, cremasteric reflex in, 958; spinal cocainization for, 540.
Sciatic nerve, multiple tumors of the, 626.
Scientific research and teaching, need of endowment for, 175.
Sclerema neonatorum, 416.
Sclerodactylia, 953.
Scleroderma, a case of diffuse, 505.
Sclerosis, family disseminated, 28.
Scotch universities, Mr. Carnegie's gift to, 1024.
Scruggs, H., death of, 663.
Scurvy in Cuba, 108; infantile, 221, 709, 824; infantile, artificial feeding in relation to, 343, 667.
Seaman, Richard S., death of, 299.
Seasickness, a journal devoted to, 38.
Seborrhœa, benzene in, 106.
Selenium compounds, poisoning by, 261.
Seminal vesicles, chronic inflammation of the, 1007; new operative method of exposing the, 393.
Septic infection, oil of turpentine in, 655; possibilities of the occurrence of, when operative technique is perfect, 835; through the stomach and duodenum, 755.
Serum, gelatinized, in gynæcology, 428; hæmolytic property of human, 1048; poisoning with, in Milan, 255; treatment with, 749.
Sewage, bacterial treatment of, 25, 304.
Sex, a case of concealment of, 143; cause of, 111.
Sherwell, S., on the effect of topical applications of excessive strength and improper diet and hygiene, in prolonging and causing skin diseases in infants and young children, 8.
Shock, effect of, in chronic glaucoma, 953; from a clinical point of view, 1017; medical, 964; surgical, 1007; use of the hot-bed in the treatment of, 745.
Shoulder, congenital dislocation of the,

186, 546; treatment of paralytic luxation of, 866.
Shrady, George F., early diagnosis of mammary tumors, 121, 155.
Sight, training of, 199.
Sigmoid sinus, ligature of the jugular vein in thrombosis of the, 732; thrombophlebitis of the, masking a latent brain abscess, 87; thrombosis of the, 503.
Silk sutures, absorption of, 149.
Simpson, William, death of, 180.
Sing Sing prison, association of the, 619; insanitary condition of, 143, 218.
Sinus thrombosis, 874; ligation of the jugular vein in, 517.
Siriasis, 147, 148.
Sitophobia of enteric origin, 832.
Skin, absorption through the, 181; diffuse chronic œdema of the, with involvement of the larynx, 24; disability in diseases of the, 788; diseases of the, in young children, causes of, 8; diseases of the, in relation to the menstrual functions, 188; general care of the, 26; phototherapy in diseases of the, 25; sensory disturbances of the, in internal diseases, 184.
Skull, perforation of the, by sarcomata originating in the orbit, 428; spoon-shaped indentations of the, in the newborn, 182.
Slevin, Walter T., ichthyol in the treatment of deep-seated inflammations, 469.
Smallpox, causative agent of, 735, 955; diazo reaction of Ehrlich in, 428; in various places, 160, 177, 341, 381, 501, 623, 660, 662, 780, 820, 950; pseudo- or modified, 972; treatment of, 877; use of calf lymph in epidemic, 640.
Smith, Alice M., postural treatment in threatened miscarriage, 732.
Smith, Alonzo T., death of, 461.
Smith, Emmet L., an easy-working, non-spilling atomizer, 679.
Smith, Mayo G., death of, 343.
Smokers, affections in, 309.
Snowden, Harold, death of, 742.
Sobel, Jacob, enlargement of the sublingual gland in infantile myxœdema, 552.
Social evil, discussion on, 397.
Sodium chloride, bactericidal action of the saturated solution of, 814.
South Africa, conduct of civil surgeons in the war in, 298; hospital scandal in, 180, 422, 552, 590, 631, 747; insanitary condition of towns in, 1061.
South Sea medicine men, 80.
Southworth, Thomas S., a plea for the conservation of breast milk in whole or in part, 686, 717.
Spain, longevity in, 479.
Spearman, Alfred, death of, 584.
Specialism, relation of, to general practice, 1008.
Spectacles, use and abuse of, 386.
Speculum, an illuminated vaginal, 877.
Sphenoid wings, pneumatic sinuses in the, 507.
Spina bifida, 921; iodine injections in the treatment of, 113; pathogenesis of, 551.
Spinal abscesses, treatment of, 23.
Spinal accessory nerve, paralysis of the, 358.
Spinal anæsthesia, 21, 73, 91, 728, 744, 746, 783, 787, 870.
Spinal cord, degenerative disease of, associated with anæmia, 62; differential diagnosis in diseases of the, 190; surgery of the, 921.
Spine, fractures of the, 295, 799; lateral curvature of the, 63; treatment of abscess of the, 878; tumor of the, 32.
Spitting nuisance, efforts to abate the, 143, 341, 581, 672.
Spitzka, Edward A., the redundancy of the preinsula in the brains of distinguished educated men, 940.
Spleen, subcutaneous laceration of the, 225; influence of, on the pancreatic digestion of proteids, 138; rupture of the, 116; surgery of the 192; tuberculosis of the, of unusual type, 275.
Splenomegaly, anæmic, 104; in cancer of the liver, 1010; in infancy, 210; pretuberculous, 54; primary, 656.
Spondylitis typhosa, 1049.
Sponges, sterilization of, by boiling, 280.
Sprague, Seth B., death of, 951.
Sprains, treatment of muscular and joint, in railway employees, 913.
Sputum, value of examination of the, to the general practitioner, 344.
Squint, latent, 187.
Squires, George W., placenta prævia, or detached placenta, 173.
Stains for fat, indifferent dye-stuffs as, 628.
Stammerers, preponderance of male over female, 624.
Stammering, prevention of, 547.
Staphylococci, predisposition to infection with, 708.
Stark, Henry S., on the diagnosis and prognosis of diabetes mellitus, 535, 557.
Starr, M. Allen, the toxic origin of neurasthenia and melancholia, 721, 753.
Static electricity in medicine, 576.
Steam disinfection in surgery, 225.
Sterility, increase of, in American women, 971.
Sterilizer, a pocket, 676.
Stern, Arthur, suppurative parotitis complicating croupous pneumonia, 637.
Stern, Heinrich, investigations upon corporeal specific gravity, and upon the value of this factor in physical diagnosis, 204; tobacco as a factor in glycosuria, 646.
Stethophonometry, 299.
Stickel, H. L., death of, 180.
Still-birth, hydrostatic test of, 240.
Stites, William, death of, 583.
Stockdell, Hugh, death of, 1006.
Stockings, dermatitis from arsenic in, 748.
Stokes-Adams syndrome, 27.
Stomach, a case of exsection of the, in New York, 544; acute ulceration of the, 369; atrophy of the mucous membrane of the, 665; bicycling in cases of disease of the, 815; cancer of the, 39; cancer of the, running a singular course, 828; chronic dilatation of, ending in death from tetanic convulsions, 64; concealed hemorrhage of the, 915; determination of the lower border of the, by the *x*-rays, 184; diagnosis of cancer of the, 657; digestion leucocytosis in cancer of the, 505; effect of diet on the osmotic tension of the, 959; effect of mastication on the secretion of the, 29; fistula into the, 548; foreign body in the, 1049; gases from the, 1049; hair cast of the, 191, 301; iodipin reaction in diseases of the, 959; operative treatment of cancer of the, 263; palliative operative treatment of cancer of the, 385; perforating ulcer of the, 12, 548; perforating ulcer of the, causing subdiaphragmatic abscess, 917; photographing the, 599; primary sarcoma of the, 346; splashing in atony of the, 828, 1012; steatolytic ferment of the, 959; surgical treatment of ulcer of the, 308, 628; total extirpation of, 750; treatment of hemorrhage from the, 346; treatment of ulcer of the, 784, 798; ulcer of the, 292; ulcer of the, sex in relation to, 106.
Stomatitis ulcerosa chronica, 1037.
Stone, George, death of, 783.
Stone, Robert, death of, 424.
Stony Wolde Sanatorium, 142, 619, 820.
Storer, Horatio R., gift of medical medals by, to the Boston Medical Library, 640.
Strabismus, treatment of, 250.
Stramonium, poisoning by, 506.
Streptococcal infection, antistreptococcus serum in, 868; following labor, 971.
Streptothrix, infection by, 755.
Stricture, continuous dilatation of urethral, 231.
Stronach, James Watson, death of, 180.
Study, Joseph N., albuminuric retinitis in pregnancy; premature labor; death in utero of twin children; puerperal convulsions; hemiplegia; acute mania; death, 654.
Sturmdorf, Arnold, nephrorrhaphy with flap fixation, 998.
Subphrenic abscess as a complication of appendicitis, 452.
Sugar, dietetic value of, 748, 858; in the urine, tests for, 225, 388.
Suicide, further remarks concerning, 1001.
Summer diarrhœa, 1055, 1057.
Sunstroke, is it an accident or a disease? 278.
Suprarenal extract as a hæmostatic, 197, 207; in Addison's disease, 956; in diseases of the heart, 823; in diseases of the middle ear, 136; in rhinological operations, 585; resorcin as a preservative of, 425, 733; uses of, 230, 748.
Surgery, disappointments in, 111; value of blood examinations in, 912; value of clinical microscopy, bacteriology, and chemistry in, 892.
Surgical operations, combined, on women at a single séance, 299; training in French medical schools, 631.
Sweatshop work, law restricting, 216.
Sydenham, Thomas, life of, 38.
Sydney, N. S. W., sanitary condition of, 179.
Symes, J. G., death of, 264.
Symphyseotomy, 719; comparison of, with Cæsarean section, 1020.
Syphilides, treatment of palmar, 400.
Syphilis, albuminuria in the early stages of, 700; clinical observations on, 792; difficulty of cure of cerebral, 867; enlargement of the inguinal glands in the diagnosis of primary, 666; fever of, 1046; hereditary nasal, 107; heredity of, 1048; in the well-to-do, 727, 819; itching of the throat in secondary, 786; league against, in France, 862; mental affections in, 184; mercurial injections in, 390, 783, 915; nitrite treatment of, 21; pyrexia of, 64; refractory to treatment, 224; supposed defensive power of the phagocytes of the lymphatic glands against, 467; treatment of, 743; urinary secretion in, 668.
Syringe, a shielded piston, for urethral and vesical irrigation, 624.
Syringomyelia, 388; gastric crises in, 150.

T

Tabes dorsalis and diabetes mellitus, 276; biceps tendon jerk in, 912; etiology and treatment of, 16; idiomuscular excitability in, 667; prognosis of, 415; recognition of, 914; throat paralysis in a case of, 1046; treatment of, 472; treatment of, the Fraenkel method, 357.
Tabes mesenterica, 1009.
Tachypnœa, nervous, 954.
Tails in man, 957.
Tanner, Charles K. D., death of, 707.
Taussig, F. J., subarachnoid cocainization in obstetrics and gynecology, 91.
Tear passage, operation for the relief of stoppage of the, 172, 239.
Teeth, and growth of children, 983; caries of the, as a factor of disease, 26; of natives of the tropics, condition of, 916.
Temperaments, application of the human, in medicine, 211.
Temperatures in healthy children, 540; reduction of, by evaporation baths, 824.
Temporal bone, cholesteatoma of the, 304.
Tendinitis rheumatica ocularis, 867.
Tendon surgery, 750; transplanting in paralytic deformities, 816.
Tenement-house bill, opinions regarding the, 543.
Tennessee State Medical Society, 661.
Tenonitis serosa, 587.
Tesson, Louis S., death of, 952.
Testicle, diagnosis of sarcoma of the, 159.
Testicular fluid, injection of, to prevent atrophy of the prostate after removal of the testes, 67.

Tetanus, 814; a case of, 472; antitoxic properties of the bile of a victim of, 38; antitoxin treatment of, 429; following cœliotomy, 1021; Fourth-of-July, 912; in infancy, 64; orrhotherapy in, 654; puerperalis, 748.
Tetany, gastric, 825.
Therapeutics, some fallacies of, 481, 511.
Thomson, Edgar S., an unusual case of partial recovery from embolism of the arteria centralis retinæ, 574.
Thorax, penetrating wounds of the, 39.
Thorburne, Richard, death of, 181.
Throat diseases, rectal feeding in, 584; nose, and conjunctiva, relation existing between diseases of the, 1008.
Thrombosis of the sigmoid sinus, ligature of the internal jugular vein for infective, 386; of the subclavian artery, 273; vulvo-vaginal, 464.
Thrush in advanced age, 955.
Thumb, method of reducing dislocations of the, 332.
Thymic death, 184.
Thymotal, 385.
Thymus, tumor of the, cured by thyroid extract, 467.
Thyroid gland, carcinoma of the, 73; medication, interesting results of, 816; operations, shaping of the stump after, 955.
Thyroiditis in typhoid fever, 1050.
Tibia, osseous cyst of the, 516; splint for transverse fracture of the, 585.
Timber, preservation of, 583.
Tobacco, alkaloids of, 559; as a factor in glycosuria, 646.
Toes, clubbed, 549.
Tokio, university for women in, 176.
Tomlinson, H. A., rest in bed in the treatment of acute mental disease, 112.
Tongue as a breeding-place for bacteria, 311; operation for cancer of the, 928; syphilitic diseases of the, 22.
Tonsils as portals of infection, 222; hemorrhage from an abscess around the, 385; hypertrophied, 343; primary malignant disease of the, 466.
Torticollis, mental, 226; treatment of, 465.
Touch, education of the sense of, in feeble-minded children, 105.
Toxæmia, mental disease from, 120.
Toxins, the bacterial, 344.
Trachea, foreign body in the, 668; impaction of a piece of orange in the, 914; removal of foreign bodies from the, 968.
Tracheal hemorrhage, post-influenzal, 416.
Tracheotomy, experience with, 356, 641.
Trachoma, management of, 868.
Training, effects of, 952.
Tremor, systemic exercise in the amelioration of, 539.
Trichinosis, excessive eosinophilia in, 1007.
Trinitrol, 632.
Trional, multiple neuritis and hæmatoporphyrinuria following the prolonged ingestion of, 626.
Triplets with a single placenta, 866.
Tropical medicine, Liverpool school of, 1024.
Tropics, meat rations in the, 503.
Tubercle bacilli, chemistry of, 755; cultivation and staining of, 305; disseminated by cows in coughing, 498; effect of coal on, 668; in food-fats, extermination of, 588; in the sputum, 27; variability of, 1007.
Tuberculin test for cattle, 380.
Tuberculosis, a bar to immigration, 947; acute, 1010; acute miliary, 753; among the poor, 457; Arloing-Courmont's serum reaction in, 507; causative treatment of, 23; collection of statistics of, 949; compulsory notification of, 656; defence against, 232; diagnosis and surgical treatment of renal, 913; duty of the State in the prevention of, 599; early diagnosis of, 344; electro-chemical action of the *x*-rays in, 385; extermination of, by dietetics and hygiene, 913; heredity of, 506; home treatment of, 1045; hygienic treatment of, among the ancients, 65; importance of early recognition of, in relation to treatment, 758; in prisons and reformatories, 334, 475; in Roumania, 27; infantile, 438; institutional treatment of, in Norway, 27; latent, of the bones or joints, value of the tuberculin test in, 615; mammary, 148, 1037; natural immunization against, 668; new treatment for, 608, 620; no specific cure for, 814; observations in, 26; of bone, 104; of fascia, 865; of the iris, 864; of the mesenteric ganglia, 1009; of the parotid gland, 959; of the pericardium, 966; of the upper-air passages, etiology, diagnosis, and treatment of, 145; of the vas deferens and seminal vesicle, 516; officers of the congress on, 860; orrhodiagnosis of, 107; peritoneal, 107; pregnancy in relation to, 54; prevention of, in babes born of tuberculous parents, 982; problems relating to, 39; prophylaxis of, 23, 297, 464, 839, 1037; renal, surgical treatment of, 1020; secondary, 692; sodium cinnamate in, 355; some anatomical lesions caused by the poisons of, 700; splenic, of unusual type, 275; surgical, discussion on, 77; treatment of laryngeal, 359; typhoid fever simulating, 540; urea in the treatment of, 463, 1047; see also *Consumptives, Phthisis*, and *Pulmonary tuberculosis*.
Tuberculous meningitis, analysis of symptoms of, 33.
Turbinated bones, cysts of the middle, 185; reduction of hypertrophy of the, 1000; surgery of the, 424.
Typhoid arthritis, 1047.
Typhoid bacillus, active substances in the cultures of the, 807; hemorrhagic infection due to, 22.
Typhoid fever, 978; abdominal pain in, 747; anæmia in 1048; anomalous cases of, 22; apparent immunity of Asiatics, 223; bacteriology of, 785; bacteriology of mild, 303; bacteriological diagnosis of, 784; complications of, 1007, 1045; diagnosis of, from appendicitis, 700; diet in, 25; disinfection of the urine in, 507; dysentery associated with, 549; etiology of, 320; experience in an epidemic of, 868; exploratory laparotomy in intestinal perforation in, 226; hemorrhagic diathesis in, 261; immunity after, 627; in South Africa, 360, 552, 630, 710; infection of, spread by linen, 218; influence of fatigue in the causation of, 239; inoculation against, 148, 659, 779, 787; intestinal perforation in, 224, 441; isolation in relation to, 880; jaundice in, 147; leucocytosis in cases of perforation in, 664; localized neuritis as a complication of, 146; operation for supposed appendicitis in, 873; orchitis complicating, 756, 801; origin and spread of, in the United States army during the Spanish war, 98; pleurisy complicating, 150; prevention of, in armies in the field, 223; pyonephrosis in, 788; rectal feeding in, 305; relation of the bowel lesion of, to the general symptoms, 147; rôle of the domestic animals in the causation of, 135; sequelæ of, 153, 1007, 1045; signs of perforation with intact bowel in, 467; simulating tuberculosis, 540; some unusual symptoms in, 575; spontaneous dislocation of the hip occurring during, 291; study of the symptoms of perforation in, 347; successful operation for perforation of the bowel in, 193; surgical treatment of, 1047; sustaining treatment of, 344; thyroiditis in, 1050; treatment of, 230, 261, 348; treatment of, in South Africa, 439; treatment of intestinal hemorrhage in, 744; treatment of intestinal perforation in, 750.

U

Ulcers of the leg, treatment of, 628.
Umbilical cord, treatment of the, 480.
University of Pennsylvania, changes in the medical course at the, 379, 459; Historical Club of the Medical Department of the, 706; medical class of '76 of the, 1005; medical laboratories of the, 861.
Upson, Charles R., important points in the management and treatment of consumption, 94.
Uræmia, osmotic pressure in relation to, 924; treatment of, 229.
Ureine, some facts regarding, 329.
Ureometer and saccharometer combined, 477.
Ureter, calculus of the, in a boy, 981; calculus of the, scratch-marks on wax-tipped bougies in the diagnosis of, 1020; calculus of the, simulating vesical calculus, 782; method of repairing by direct suture, 495; obliteration of the right, by a calcified fibroid, 221; reflux of the vesical contents into the, 320; traumatic injuries of the, 76; tuberculosis of the, 677; vesical implantation of the, by Dudley's forceps method, 221.
Ureteritis, operation for calculous, 973.
Uretero-ureteral anastomosis, relative merits of the different methods of, 929.
Urethra, dilator of the, with modified handle, 1008; fallacies in the treatment of diseases of the, 967; fibromyoma of the female, 78; peculiar micro-organism in a discharge from the, 792; prolapse of the female, 1010; rupture of the, 790; surgical asepsis of the, 105.
Urethritis membranacea, 106; treatment of post-gonorrhœal, 1032.
Uric-acid diathesis, 185, 943; lesions, oxygen treatment of, 184; the problem of, 744; toxæmia, inheritance of, 814.
Urinary tract, bacterial infection of the, 275.
Urination, frequent painful, guaiacol in, 22.
Urine as a culture medium, 755; blue, 953; casts in the, without albumin, 136; conservative operation for renal retention of, 550; delicate test for sugar in the, 225; excretion of, in neurasthenia, 112; immediate examination of the, to determine the specific gravity, 449; phenyl-hydrazin test for sugar in the, 388; test for diacetic acid in the, 506.
Urotropin as a urinary antiseptic, 182.
Urticaria factitia accompanying scleroderma, 712; pleuritic, 375; with albuminuria, 668.
Uterine appendages, conservative operations upon the, 271.
Uterus, acute puerperal inversion of the, 428; adenoid changes in the cervix, during pregnancy, labor, and the puerperium, 66; Cæsarean section for fibrocystic tumor of the, 615; calcareous fibroma of the, 78; calcium carbide in the treatment of cancer of the, 1046; cancer and fibroma coexisting in the corpus, 547; cancer of the body of the, 183; cancer of the cervix, 677, 928; cancer of the fundus, 1015; cause and significance of hemorrhage from the, 313; circulatory phenomena as sequelæ of the pregnant, 152; congenital hypertrophy of the cervix, 113; curability of cancer of the, 148; dilatation of the cervix, 719; fibroids of the, 344, 593; fibroids of the, complicating pregnancy, 436, 719; hitherto unknown form of stenosis of the, 464; hyperæsthesia of the, during pregnancy, 733; improved technique in the surgical treatment of myomata of the, 1013; injections in diseases of the, 960; intraligamentous cysts, 1013; myomata of the, 928; one hundred and twenty fibroids in a, 626; operations for lacerations of the cervix, 434; operations for retrodisplacements of

the, 75; origin of fibroid growths of the, 267; pathology and surgical treatment of tumors of the, 733; prolapse of the, 551, 1016; prolapse of the, vaginal hysterectomy for, 114; removal of epithelioma of the cervix during pregnancy, 388; retraction of the, with special reference to the third stage of labor, 629; retroflexion and retroversion of the pregnant, 576; retroversion of the, 869; round-ligament ventro-suspension of the, 1007; sarcoma of the, 262, 954; shortening the round ligament, 519; spontaneous delivery of a polyp of the, 114; subinvolution of the, 868; treatment of infection arising in the, 24; treatment of retrodisplacements of the, 277, 969; tumors of, in infancy and early life, 732; use of the Paquelin cautery in the cavity of the, 115.
Uvula, mechanical constriction of the, 23; pulsation of, in aortic insufficiency, 1007.

V

Vaccinia and smallpox, relation of, 826; causative agent of, 735, 828, 955; serous, in connection with cretinism and rickets, 787.
Vaccination, aseptic, 524, 555; clinically considered, 546; compulsory, in Pennsylvania, 582; in Paris, 79; keloid on a scar following, 730; Mrs. Eddy on, 380; obligatoriness of, 107; technique of, 550.
Vagina, atresia of the, 928; double, with a single uterus, 185; false membrane in the, due to bacterium coli, 747; prolapse of the, 551; sarcoma of the, 954.
Vaginal speculum, an illuminated, 877.
Vagitus uterinus, 465.
Valentine, Ferd. C., chronic gonorrhœa and post-gonorrhœal urethritis—a sketch of their modern treatment, 1032.
Valentine, Richard K., death of, 502.
Van Fleet, Frank, the bill to regulate medical practice, 238; the new medical bill, 307.
Van Zandt, I. L., creosote in pneumonia: a *résumé*, 492.
Varicella, rash of, 107.
Varices, guaiacol in the treatment of, 389.
Varicocele, guaiacol in, 389.
Varicose ulcers, treatment of, 399; veins of the abdomen and extremities, 872; veins, treatment of, 551.
Veins, lateral and circular suture of, 954.
Veld sores, 223, 710, 915, 1048.
Vena cava, rupture of the inferior, 914; thrombosis of the inferior, 834.
Venereal disease a social problem, 547; circumcision as a preventive of, 541; prophylaxis of, 954.
Veratrum viride, 615.
Vernon, Bawater J., death of, 306, 343.
Version, indication, technique, and limitation of, 692, 719; spontaneous, 627.
Vice and the church, 734.
Virchow fund, 621.
Virginia, convicts in, 545; report of the Central State Hospital of, 319.
Vision, injury to the earning capacity of the individual from partial or complete loss of, 440; neurotonic architecture of the organ of, 386.
Vitalis, Othan, death of, 198.
Vitality after severe injury, 1009.
Vital statistics, practical use of, 838.
Vitiligo, etiology of, 150.
Vivisection in England, 949.
Volvulus complicated with hemorrhage, 782.
Vomiting of pregnancy, sodium bicarbonate in, 390; recurrent, of nervous origin, 645.
Vratch, 861, 910, 1005.

W

Wachenheim, F. L., a case of fatal stenosis of the larynx following intubation for papilloma, 469.
Waggener, Richard, some facts bearing upon the malarial problem, 469.
Wagner, R. V., static cataphoresis, 160.
Waite, E. E., death of, 1044.
Ware, Martin W., the field for ethyl chloride narcosis, 533.
Wasdin, Eugene, generalized gonorrhœal infection, 918.
Water, relative merits of slow sand and mechanical filtration, 139.
Water-itch, 467.
Weiss, Ludwig, chronic gonorrhœa and marriage, 447.
Wells, John A., death of, 823, 864.
Wells, J. Hunter, the use of the hot-bed in Korea in the recovery-room and for treatment of surgical and other shock, and similar conditions, 745.
Werlhof's disease, bichloride of mercury in, 226.
West, Mary S., death of, 500.
West Point training, nervous exhaustion due to, 1046.
Western Surgical and Gynæcological Association, 72.
Whistling spells in brain injury following operation, 480.
Whitbeck, Henry D., death of, 864.
Whooping-cough, irrigation of the nares in, 786; pathology of, 978; treatment of, 14, 105, 399, 749.
Widal reaction in typhoid fever, 14; plea for uniformity of technique in, 825; technique of the, 462; value of infancy and childhood, 868.
Wienges, Conrad, death of, 864; resolutions on the death of, 911.
Williams, J. Frank, death of, 707.
Winn, James Mitchell, death of, 69.
Witham, Wright Lane, death of, 912.
Women as hospital internes, 560; hospital appointments for, 708; medical education of, in Russia, 856; medical profession for, 479; medical students, Dr. Vaughan on, 581; students in college, susceptibility to disease and physical development of, 664.
Women's Medical Association of New York City, 142.
Woodruff, Charles E., the treatment of gonorrhœa with frequent irrigations of hot decinormal salt solution, 401.
Woodward, Henry L., Jr., honors to, 780.
Woodward, J. H., strabismus and its management, 250.
Worcester, William Leonard, death of, 1044.
Wounded, care of, in naval warfare, 1038.
Wounds, closing of cutaneous, without suture, 259.
Wren, George, death of, 502.
Wright, Jonathan, the non-myxomatous character of nasal polypi, 132.
Wrist, injuries to the, 13; resection of the, by Studsgaard's method, 826.
Wrist-drop due to traumatism of the musculo-spiral nerve, 230.
Wyeth, John A., the value of clinical microscopy, bacteriology, and chemistry in surgical practice, 892.
Wynkoop, Edward Judson, ether as an anæsthetic, 852.

Y

Yale Medical School, clinical buildings for, 383.
Yaws in Fiji, 916.
Yellow fever and mosquitos, 58, 81, 201, 269, 1042; etiology of, 387, 474; experimental, 754; immunity against, 839; international commission for the study of, 232, 312; on the Gold Coast, 712; period of incubation of, 361, 459; prophylaxis of, 308; serum, rival claimants for a, 949; spread of, in houses, 933; study of the propagation of, 201; treatment of, 310.
Youmans, William J., death of, 624.

Z

Zona, an epidemic of, 960.
